Changes in Urologic and Medical Treatment of Cystinuric Patients Over Time Caroline Prot-Bertoye,[1] Said Lebbah,[2] Michel Daudon,[3] Isabelle Tostivint,[4] Olivier Traxer,[5] Bertrand Knebelmann,[6] Marie Courbebaisse.[1] *[1]Physiology, APHP, Georges Pompidou European Hospital, Paris, France; [2]Biostatistics, AP-HP, Necker Hospital for Sick Children, Paris, France; [3]Physiology, AP-HP, Tenon Hospital, Paris, France; [4]Nephrology, AP-HP, Pitié-Salpétrière Hospital, Paris, France; [5]Urology, APHP, Tenon Hospital, Paris, France; [6]Nephrology, AP-HP, Necker Hospital for Sick Children, Paris, France.*

Background: Cystinuria is the most common monogenic nephrolithiasis disorder, but few studies have described its urological and medical treatment in a large cohort.

Methods: We retrospectively collected data from 442 French cystinuric patients. Clinical and laboratory data, urological and medical treatments were described. A mixed-effects logistic regression model was used to estimate the effects of urinary pH, urinary specific gravity, and cysteine-binding thiol agents (CBT) on the risk of cystine crystalluria.

Results: The median follow-up [min-max] was 15.8 years [0.1-65.6]. The average annual rate of surgical procedures increased with time (P<0.001). During the period 2000-2004, 7.3 % of patients had at least one flexible ureteroscopy, versus 23.2 % after 2005 (P<0.001). CBT were prescribed for 55.3% of patients. Prescription of tiopronin increased with time in newly symptomatic patients (P<0.001). At least one side effect was recorded in 23.7% of patients treated with tiopronin, and 30.2% of patients treated with D-penicillamine (P=0.23). Increasing urinary pH and decreasing urinary specific gravity significantly reduced the risk for a patient to have a cystine crystalluria whereas D-penicillamine and tiopronin did not reduce this risk. The estimated probability of cystine crystalluria was 45%, 38%, 31% and 25% for an urinary pH of 6.5, 7.0, 7.5 and 8 and was 52%, 31% and 16% for an urinary specific gravity of 1015, 1010 and 1005.

Conclusions: The number of urological interventions and the prescription of tiopronin has increased over time. We show for the first time that D-penicillamine and tiopronin don't impact cystine crystalluria although inducing frequent adverse effects in the same proportions. Urinary pH above 7.5 and morning urinary specific gravity below 1005 should be the goals of medical therapy.

FR-PO180

Defect of Interdependent Membrane Targeting and Endocytosis of Cubilin and Amnionless Leads to Imerslund-Gräsbeck Syndrome Tomohiro Udagawa,[1] Ken-ichiro Miura,[1] Akihiko Saito,[2] Yutaka Harita.[1] *[1]Pediatrics, Graduate School of Medicine, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan; [2]Applied Molecular Medicine, Niigata Univ Graduate School of Medical and Dental Sciences, Chuo-ku, Nigata, Japan.*

Background: Imerslund-Gräsbeck syndrome (IGS) is an autosomal recessive disorder characterized by low-molecular-weight proteinuria and megaloblastic anemia. IGS is caused by mutations of either cubilin (*CUBN*) or amnionless gene (*AMN*). Cubilin forms protein complex with amnionless (cubam complex) and functions as the receptor-mediated endocytotic machinery.

Methods: A six year-old boy with history of megaloblastic anemia was diagnosed with IGS because of low-molecular weight proteinuria. Whole-exome sequencing identified novel heterozygous missense mutations, one each in *CUBN* and *AMN*. The *CUBN* mutation was de novo and the *AMN* mutation was inherited from a healthy parent.

Results: Renal biopsy showed translocation of amnionless from the apical membrane to the cytoplasm of proximal tubular cells. Using cultured cells, the mechanism of membrane trafficking of cubam and the effect of the mutations were analyzed. Although wild-type cubilin and amnionless were interdependently targeted to the cell membrane, the *CUBN* or *AMN* mutation abrogated membrane expression and endocytosis without affecting the interaction between cubilin and amnionless. Coexpression of amnionless induced maturation of cubilin protein, and the modification were identified by stable isotope labeling using amino acids in cell culture (SILAC)-based quantitative mass spectrometry. Notably, the *CUBN* mutation completely abrogated the amnionless-dependent glycosylation of cubilin. Tunicamycin or substitution of several Asn residues to Asp abrogated membrane targeting of cubam without affecting cubilin and amnionless interaction, further supporting a role of cubilin glycosylation.

Conclusions: Our results demonstrate that digenic heterozygosity can lead to IGS and suggest that interdependent membrane trafficking of cubam complex mediated by posttranslational modification is crucial for the renal and intestinal absorption.

FR-PO181

Metabolic Control of Nephron Progenitor Cell Renewal and Differentiation Anna Abrams, Jiao Liu, Zubaida R. Saifudeen. *Pediatrics, Tulane Univ, New Orleans, LA.*

Background: Nephron progenitor cells (NPC) availability and differentiation potential determine nephron endowment. Emerging data from embryonic stem cells and other developing systems emphasizes the significance of energy metabolism in cell fate determination. Systemic metabolic dysfuntion such as hyperglycemia alters neural and adipocyte stem cell fate. Nephron deficit in kidneys of infants of diabetic mothers (idm) is known; however the effect on NPC and nephrogenesis under maternal hyperglycemia are unknown. Metabolic parameters of renewing NPCs are also unknown. Based on published stem cell data, we hypothesized that NPC self-renewal and differentiation are balanced by energy metabolism.

Methods: a. Fetal kidneys were exposed to maternal hyperglycemia using Streptozotocin (STZ). P0 kidney sections were immunostained to detect apoptosis (active caspase3) in the CM (Six2 and NCAM) and nascent nephrons (Lef1 and NCAM). b. Glycolysis was inhibited ex vivo in E12.5 kidneys by pharmacological inhibition of PFKFB3 (YN1 5-25nM). c. Glycolysis and oxidative phosphorylation were measured in NPC of Six2CreGFP+;p53fl/fl, a genetic model of impaired cap mesenchyme renewal.

Results: a. CM of P0 kidneys of STZ-treated females showed increased apoptosis and reduction in nascent nephron number (Lef1+ and NCAM+). b. Glycolysis inhibition resulted in a smaller dispersed CM, accelerated but not ectopic differentiation of the NPC with up to a 50% increase in Lhx1+ nascent nephrons 24-48h post-treatment, and decreased Cited1 expression by QPCR in isolated NPC. UB tip and branch numbers were unchanged. Thus, increased nephrogenesis was independent of UB branching. Expression of Wnt4 was unchanged. c.Conditional deletion of p53 in NPC also resulted in dispersed CM, depletion of the Cited1+/Six2+ NPC independent of apoptosis, and hypoplastic kidneys with fewer nascent nephrons. Isolated mutant cells show reduced basal oxygen consumption rate and decreased maximal respiratory capacity. Accordingly, the mutant cells exhibit a significant, nearly two-fold decrease in ATP ($p<0.005$, n=3).

Conclusions: Our data are consistent with the idea that the metabolic status of the NPC is a critical determinant of NPC renewal and differentiation.

Prorenin Receptor Signaling Promotes Nephron Induction During Mouse Kidney Development Renfang Song,[1] Graeme James Preston,[1] Laura R. Kidd,[2] Ihor V. Yosypiv.[1] *[1]Pediatrics, Tulane Univ, New Orleans, LA; [2]Pathology, Tulane Univ, New Orleans, LA.*

Background: Deficient nephrogenesis is the major factor contributing to congenital renal hypodysplasia (RHD), one of the leading causes of childhood end-stage kidney disease. Nephron induction is driven by reciprocal interactions between progenitor cells of the cap mesenchyme and the ureteric bud (UB).

Methods: To determine the potential role of the prorenin receptor (PRR) in nephrogenesis, we generated mice with a conditional deletion of the *PRR in Six2-positive nephron progenitors* of the cap mesenchyme and their epithelial derivatives ($Six2^{PRR-/-}$).

Results: Inactivation of *PRR* in nephron progenitors caused a marked decrease in the number of developing nephrons, severe congenital RHD with collapsed glomeruli and an enlarged Bowman's space (such as those seen with a collapsing FSGS), podocyte foot process effacement and early postnatal death within 48 hours from birth. UB branching was greatly reduced, likely secondary to decreased nephrogenesis. Reduced congenital nephron endowment resulted from premature depletion of nephron progenitor cell population due to impaired progenitor cell proliferation and loss of normal molecular inductive response to canonical Wnt/*β-catenin signaling within the metanephric mesenchyme. At 2 months of age, heterozygous* $Six2^{PRR+/-}$ mice exhibited focal glomerulosclerosis, decreased kidney function and massive proteinuria.

Conclusions: Collectively, these results are consistent with a cell-autonomous requirement for the PRR within nephron progenitors for progenitor maintenance, induction of nephrogenesis, normal kidney development and function. Thus, *PRR* is a potential candidate for future genetic screening studies in patients with congenital RHD and proteinuric kidney disease.

FR-PO183

Functional Dissection of Enhancers for *Bmp7* in Kidney Development Taro Tsujimura,[1,2,3] Osamu Takase,[1,2,3] Masaomi Nangaku,[2] Keiichi Hishikawa.[1,2,3] *[1]Advanced Nephrology and Regenerative Medicine, The Univ of Tokyo Hospital, Tokyo, Japan; [2]Div of Nephrology and Endocrinology, The Univ of Tokyo Hospital, Tokyo, Japan; [3]Div of Tissue Engineering, The Univ of Tokyo Hospital, Tokyo, Japan.*

Background: Bmp7 is a critical player in the kidney development, as shown by its sever retardation in the KO mice of the gene and their subsequent perinatal lethality due to the malfunction. Previous studies identified two potential enhancers for the *Bmp7* expression in the developing kidney around the locus: one residing inside the 1st intron of *Bmp7* for expression in the developing ureteric bud; the other located downstream of the 3' end of *Bmp7*, which is rather active in the metanephric mesenchymal cells. Consistently, *Bmp7* is also expressed in these two distinct domains. However, neither the requirement of these elements nor the precise roles of Bmp7 secreted from these different cell types for the kidney development has been uncovered so far. In this study, we aimed to characterize the roles of the two enhancers to better understand the *cis*-regulation of *Bmp7* and the kidney development.

Methods: We established and analyzed homozygous mice carrying a large genomic deletion of the downstream region of *Bmp7* including the mesenchymal enhancer.

Results: We found that they have significantly smaller body size than their wild type littermates, although they are viable unlike the KO mice of *Bmp7*. We previously showed that the same deletion also disrupts the topological partition of the chromatin conformation between the *Bmp7* domain and the neighboring one of another developmental gene, *Tfap2c*, resulting in a merger between them (Tsujimura *et al. PLoS Genetics* 2015). Interestingly, upon this deletion, we scored significant up-regulation of *Tfap2c* in the kidney probably by the action of the intron enhancer.

Conclusions: These results suggest that the endogenous genomic context guarantees robustness in the regulation of the kidney development by linking the more important ureteric bud enhancer to *Bmp7* tightly. The differential roles of the two enhancers will be further discussed based on the histological and functional analysis of the kidney in the homozygous deletion mice.

FR-PO184

BMP7 Regulates Expansion of the Postnatal Nephron Mary E. Taglienti,[1] Seymour Rosen,[2] Jordan A. Kreidberg.[1,3,4] *[1]Dept of Medicine, Boston Children's Hospital, Boston, MA; [2]Dept of Pathology, Beth Israel Deaconess Medical Center, Boston, MA; [3]Dept of Pediatrics, Harvard Medical School, Boston, MA; [4]Harvard Stem Cell Inst, Cambridge, MA.*

Background: The factors that regulate the expansion of nephrons after their initial induction and differentiation are largely unknown. Bone morphogenic protein 7 (BMP7) is a crucial factor driving proliferation and self-renewal of nephron progenitor cells during the development of the embryonic kidney. In this study we investigated a potential role for BMP7 as a regulator of post-induction nephron growth and differentiation.

Methods: The Bmp7 gene was conditionally mutated in progenitor cells using Six2-GFP/Cre. Kidneys from mutant and control mice were analyzed using a novel approach to quantify proximal tubule expansion as an indicator of nephron growth in the postnatal mouse.

Results: Kidneys of Bmp7 conditional mutant mice were smaller with reduced numbers of nephrons. Bmp7 was expressed in developing nephron tubules of control kidneys and was absent from mutant kidneys. Proximal tubule growth, as determined by computationally measuring the area of lectin-stained proximal tubules in postnatal kidneys, was reduced in mutant kidneys. However, the proximal tubule area per glomerulus was increased in mutant kidneys, indicating that those nephrons that were induced underwent hypertrophy. Proliferation, as defined by Ki67+ nuclei per LTL lectin+ cells within the proximal tubule compartment, was initially greater in mutants but declined by P10.

Conclusions: Loss of Bmp7 in progenitors leads to low nephron number. Bmp7 appears to be an important driver of postnatal nephron expansion. This phenotype is similar to oligomeganephronia and may be used to understand the basis for nephron hypertrophy in low nephron number situations.

FR-PO185

Grainyhead-Like 2 (Grhl2) Regulates Collecting Duct Barrier Function, Aquaporin 2 Expression and Urinary Concentration Christian Hinze,[1,2] Janett Ruffert,[2,5] Katharina Walentin,[2] Max Werth,[3] Jonathan M. Barasch,[3] Andong Qiu,[3] Kerim Mutig,[4] Sebastian Bachmann,[4] Kai M. Schmidt-Ott.[1,2] *[1]Dept of Nephrology, Charité-Universitätsmedizin, Berlin, Germany; [2]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [3]Div of Nephrology, Columbia Univ, New York; [4]Dept of Anatomy, Charité-Universitätsmedizin, Berlin, Germany; [5]Urological Research Laboratory, Charité-Universitätsmedizin, Berlin, Germany.*

Background: Osmotic homeostasis is tightly regulated by the kidney and its collecting ducts which form tight barriers, thereby maintaining steep concentration gradients and allowing transcellular reabsorption of water via aquaporins. The transcription factor grainyhead-like 2 (Grhl2) is highly expressed in renal collecting ducts. Using cultured collecting duct cells, we recently showed that Grhl2 regulates epithelial barrier formation and lumen expansion via a target gene set comprising the transcription factor Ovo-like 2 (Ovol2), the small GTPase Rab 25 (Rab25) and the tight junction component claudin 4 (Cldn4). The role of Grhl2 in the collecting duct *in vivo* is unknown.

Methods: To investigate the role of Grhl2 in the renal collecting duct, we generated a collecting duct-specific knockout with Hoxb7/Cre; $Grhl2^{flox/-}$ mice, which exhibit a deletion of Grhl2 protein in most cells of the collecting duct. The molecular and cellular alterations in their kidneys and their response to water deprivation were analyzed.

Results: Transcriptional profiling of Hoxb7/Cre; $Grhl2^{flox/-}$ mice kidneys and control littermates showed deregulation of Ovol2, Rab25 and Cldn4, but also differential expression of Aquaporin 2 (Aqp2). Following water deprivation, Grhl2-deficient mice displayed significantly lower urinary osmolality at 6 hours ($P=0.001$) and 24 hours ($P=0.04$) when compared to control mice. Moreover, Grhl2-deficient mice had more than 35% more urine volume during the first 24 hours in response to water deprivation when compared to controls ($P=0.005$).

Conclusions: Our data indicate that Grhl2 critically participates in water homeostasis, epithelial barrier function and Aqp2 expression. This might be of relevance to diseases involving defective renal responses to water deprivation.

FR-PO186

Loss of the Transcription Factor Tcf21 in the Renal Stroma Leads to Polyuria and Defects in Tubular Development Shintaro Ide,[1] Yoshiro Maezawa,[1] Rizaldy P. Scott,[2] Tuncer Onay,[2] Kana Ide,[1] Minoru Takemoto,[1] Koutaro Yokote,[1] Susan E. Quaggin.[2] *[1]Clinical Cell Biology and Medicine, Chiba Univ Graduate School of Medicine, Chiba, Japan; [2]Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

Background: Renal stromal cells serve as a supportive framework for nephrons and the collecting duct network, produce erythropoietin, and contribute to renal fibrosis when they undergo myofibroblast-like transformation. Tcf21/Pod1 is a bHLH transcription factor

strongly but not restrictively expressed in the developing renal stroma. Conventional Tcf21 knockout mice die perinatally and have maldevelopment of nephrons and mispatterning of the renal interstitium. However, the precise function of Tcf21 within renal stromal cells has yet to be clarified as Tcf21 is also expressed within the condensing metanephric mesenchyme during development.

Methods: In order to characterize the role of Tcf21 in stromal development and function, we bred floxed Tcf21 mice with Foxd1-Cre mice allowing specific inactivation of Tcf21 within the developing renal stroma and its derivatives.

Results: Mice lacking Tcf21 in the renal stroma ($Tcf21^{str/str}$) do not have an overt phenotype at birth and exhibit normal ureteric bud branching in embryonic kidney explant cultures. However, by 4 weeks postnatal, $Tcf21^{str/str}$ mutant mice develop polyuria similar to diabetes insipidus. Polyuric mutant mice produce urine with significantly reduced osmolarity and creatinine levels but with higher levels of sodium and chloride relative to control littermates. Mutant kidneys are smaller, have a disorganized interstitium, and shriveling of the medullary rays due to a reduction in the loops of Henle and collecting ducts, whereas proximal tubule densities appear undisturbed.

Conclusions: Specific inactivation of Tcf21 in the stroma causes polyuria underscoring an important role of the renal interstitium in regulating postnatal development of tubules critical for urine concentration. Identification of direct targets of Tcf21 will provide novel insights regarding interactions between stromal cells, renal tubules and the collecting ducts.

FR-PO187

Genetic Deletion of Cyclooxygenase-2 Impairs Glomerular Slit Diaphragm Formation During Late Stages of Kidney Development Kirsten Madsen,[1,2] Niels Marcussen,[2] Boye Jensen.[1] *[1]Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; [2]Dept of Pathology, Odense Univ Hospital, Odense, Denmark.*

Background: Renal cyclooxygenase-2 (COX-2) expression is necessary for normal glomerular development. Impaired COX-2 activity has been associated with decreased expression of VEGF, a vascular growth factor of significant importance for glomerular capillary development. Therefore experiments were designed to test the hypothesis that COX-2 expression supports glomerular development through stimulation of capillary loop formation.

Methods: Kidney tissue was collected from a developmental series of COX-2 knockout (KO) mice and wild-type littermates (WT).

Results: Renal COX-2 expression showed developmental regulation with significantly higher COX-2 expression at postnatal (P) days 1 and P7 than at any later time points (P14, P21 and P40). Quantitative unbiased stereology at P28 showed significantly reduced glomerular number in COX-2 KO mice compared to WT littermates (8188 ± 781 and 12251 ± 454 glomeruli/kidney respectively, P=0.0001). Subcapsular accumulation of small and immature glomeruli was seen in COX-2 KO mice whereas glomeruli deeper in the cortex towards the medullary junction appeared normal. Tissue abundance of VEGF, angiopoietin-1 and -2 mRNAs was significantly reduced in COX-2 KO mice compared to WT at P7. By electron microscopy at P28, immature subcapsular glomeruli showed normal appearance of fenestrated endothelial cells but severe podocyte foot process effacement and absence of mesangial cells. Normal morphology was confirmed in glomeruli deeper in the cortex. At P7, COX-2 KO mice showed reduced expression of slit diaphragm proteins nephrin and podocin but not synaptopodin compared to WT.

Conclusions: In summary, deletion of COX-2 leads to decreased renal expression of vascular growth factors without changes to glomerular endothelial cell ultrastructure and severe podocyte foot process effacement and impaired expression of slit diaphragm proteins. In conclusion, COX-2 activity is necessary for normal podocyte function and slit diaphragm formation during late stages of kidney development.

FR-PO188

Functional Cross Talk Between Tyrosine Phosphorylation of Crumbs Homolog 2 and Mechanistic Target of Rapamycin Complex1 in Developing Podocyte Sho Hamano, Yukino Nishibori, Kunimasa Yan. *Dept of Pediatrics, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.*

Background: Mutation of crumbs homolog 2 (CRB2) is a novel cause of congenital nephrotic syndrome. CRB2 is suggested to function in apical polarity and epithelial integrity; however, how CRB2 functions in podoyte development is unknown. Other isoform: CRB3 is known to be involved in deactivation of mechanistic target of rapamycin complex1 (mTORC1): a master regulator for cell growth. The objective of the present study is to determine functional cross talk between CRB2 tyrosine phosphorylation and mTORC1 pathway and the relevance of CRB2-mTORC1 interaction to podocyte development.

Methods: MDCK cells expressing mouse full-length CRB2 or mutated-CRB2 lacking tyrosine phosphorylation site were established. Specific antibodies against CRB2 intracellular domain (int-CRB2Ab) or tyrosine phosphorylation site (pY-CRB2Ab) were generated. The samples from cultured cells and rat kidneys were subjected to Western blot study and immunofluorescence microscopy.

Results: Int-CRB2Ab determined CRB2 to locate at the apicobasolateral membrane in wild-CRB2 cells. Specificity of pY-CRB2Ab was confirmed by using samples from mutated-CRB2 cells and wild-CRB2 cells treated with protein tyrosine phosphatases inhibitor. Int-CRB2Ab identified that CRB2 expression commenced at the comma-shaped body stage, observed in the apical side of glomerular epithelium. CRB2 in the S-shaped body was still visible at the apical side of immature podocytes, then translocated along the lateral side to basal side during capillary stage.At the mature stage, CRB2 was observed in the podocyte foot processes. In contrast, phosphorylation of CRB2 was determined faintly in immature podocyte at the S-shaped body stage, intensely at the capillary stage and then disappeared at the mature stage. mTORC1 pathway was strongly activated in the podocyte at the mature stage, but was not in immature podocyte. Finally, mTORC1 in mutated-CRB2 cells was activated more than that in wild-CRB2 cells.

Conclusions: CRB2 tyrosine phosphorylation may regulate energy system of developing podocytes through suppressing excessive mTORC1 activation.

FR-PO189

Specific Deletion of Early B Cell Factor 1 within the Kidney Mesanguim Recapitulates the Abrogated Renal Development Present in the Global Knockout Jackie A. Fretz, Tracy Nelson, Li Li. *Orthopaedics and Rehabilitation, Yale School of Medicine, New Haven, CT.*

Background: Globally deficient mice lacking the transcription factor Ebf1 (Ebf1 KO) are extremely sick owing to the multiple functions of Ebf1 across the body. We recently described a novel function of Ebf1 as an essential component of the latest stages of metanephric development. Within the kidney Ebf1 is present within multiple cell types including distinct tubular epithelium, interstitial pericytes, glomerular mesanguim, and podocytes. This investigation aimed to identify if the actions of Ebf1 in the mesangium and pericytes was driving the developmental defects present in the global knockout.

Methods: In this study we made a specific deletion of Ebf1 within the Foxd1+ lineage using a cre-driver that targets the progenitors of the kidney glomerular mesanguim and interstitial pericytes and mating these with mice where the 3rd exon of Ebf1 (encoding part of the DNA-binding domain) is flanked by flox sites. This is the same genetic region that is excised in the global deletion model.

Results: Restricted deletion of Ebf1 from Foxd1-lineage cells resulted in development of hypoplastic kidneys, poorly differentiated peripheral glomeruli, and decreased proximal tubular mass. Renal insufficiency was apparent at P21 (one week later than Ebf1 KO mice), with the appearance of proteinuria and 2+ leukocytes in urine. Growth of the animals is normal until P25, and approximately a third of the Foxd1+,Ebf1fl/fl mice die before they are 3 months old. This phenotype is similar to that seen in the Ptgs2/Cox-2 insufficient models (chemical inhibition and genetic deletion), and mechanistic investigation revealed impaired Ptgs2 expression in both the global KO and Foxd1-specific Ebf1 deletion models.

Conclusions: Taken together these results suggest that Ebf1 regulates metanephric development mainly through its actions in the mesangial lineage where it participates in proper regulation of prostaglandin biosynthesis.

Epithelial Cell Fate in the Nephron Tubule Is Mediated by the Etv5a Transcription Factor During Zebrafish Kidney Development Amanda N. Marra, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: Kidney development requires the differentiation and organization of discrete nephron epithelial lineages, however the genetic and molecular pathways involved in these events remain poorly understood. The embryonic zebrafish kidney, or pronephros, provides a simple and useful model to study nephrogenesis.

Methods: The pronephros is comprised of two types of epithelial cells: transportive and multi-ciliated cells (MCCs). Transportive cells occupy distinct tubule segments and are characterized by expression of solute transporters, while MCCs function in fluid propulsion and are dispersed in a "salt-and-pepper" pattern in the tubule. Epithelial cell identity is reliant on interplay between the Notch signaling pathway and retinoic acid (RA) signaling, where RA promotes MCC fate by inhibiting Notch signaling in renal progenitors, while Notch activity acts downstream to trigger transportive cell formation and restrict MCC identity. Previous research has shown that *etv5a* and its ETS family members are required for ciliogenesis in other zebrafish tissues.

Results: Here, we mapped *etv5a* expression to renal progenitors that occupy domains where MCCs later emerge. Thus, we hypothesized that *etv5a* is required for ciliogenesis of MCCs in the nephron. *etv5a* loss of function produced a decline of MCC number and reduced expression of the MCC markers *odf3b* and *centrin*, where rescue experiments partially restored wild-type MCC number. In epistatic studies, exogenous RA treatment expanded the *etv5a* domain, indicating that *etv5a* acts downstream of RA. Additionally, treatment with exogenous RA partially rescues the reduced MCC phenotype after loss of *etv5a*. Further, abrogation of Notch with the small molecule inhibitor DAPT increased *etv5a* expression, while overexpression of Notch using a transgenic line reduced the *etv5a* domain, suggesting Notch acts upstream to inhibit *etv5a*.

Conclusions: Taken together, these findings provide novel insights about the mechanisms of epithelial cell development during nephrogenesis.

FR-PO191

Emx1 Is Essential for Distal Segment Development During Nephrogenesis Elvin E. Morales, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: Vertebrate kidneys are comprised of functional subunits called nephrons that typically have three basic parts: a renal corpuscle, a tubule with proximal and distal segments, and a duct. The developmental pathways that establish nephron segment identities from renal progenitors remain poorly understood.

Methods: The zebrafish embryo forms a simple two-nephron pronephric kidney that possesses a conserved segment anatomy with higher vertebrates. *emx1* is a homeobox gene that, along with its paralog *emx2*, is known for playing essential roles in brain development. While both genes are expressed in the pronephros, their roles in nephrogenesis have not been established. Using whole mount *in situ* hybridization, we found that *emx1* and *emx2* were dynamically expressed in renal progenitors, and became localized to the distal and proximal segments, respectively.

Results: In knockdown studies, *emx1* morphants formed a normal distal domain, marked by *clcnk*, but within it formed an expanded distal early (DE) segment, marked by *slc12a1*, and a reduced distal late (DL) segment, marked by *slc12a3*. These data suggest that *emx1* is essential to promote the DL, and may restrict the DE and/or negotiate the site of the DE/DL boundary. Furthermore, *emx1/2* expression is responsive to changes in retinoic acid (RA), which is essential to induce proximal segments and repress distal segments during nephrogenesis. RA treated embryos had a restricted *emx1* domain and expanded *emx2* domain, while exposure to the RA biosynthesis inhibitor DEAB conversely expanded *emx1* and restricted *emx2* expression. These data suggest that RA signaling acts upstream of both genes in renal progenitors, positively regulating *emx2* and negatively regulating *emx1*.

Conclusions: Future studies will define the role of *emx2*, independently explore *emx1/2* nephron patterning functions with CRISPR-Cas lines, and assess the relationship of these *emx* genes to other factors, such as *irx3b*, that have been shown recently identified to be components of the gene regulatory networks that direct nephron segmentation. Preliminary data looking at factor interactions suggest that *emx* genes may be located downstream of them or work independently.

FR-PO192

Prostaglandins as Regulators of Nephron Proximo-Distal Cell Fate Decisions Shahram Jevin Poureetezadi, Christina N. Cheng, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: To date, there have been a number of important discoveries furthering our understanding of nephron segmentation. Despite this, the factors that direct nephron cell-fate decisions remain largely unknown. *Danio rerio*, the zebrafish, possess an embryonic kidney composed of two nephrons and a blood filter that share a remarkable degree of genetic, structural, and functional homology with the human nephron and when coupled with genetic tractability, *ex utero* development, and optically transparent embryos make it a cutting-edge model to study nephrogenesis.

Methods: The zebrafish embryonic kidney, the pronephros, is organized in a proximal-distal pattern of contiguous segments much like the human nephron. The proximal segments, the proximal convoluted tubule (PCT) and the proximal straight tubule, share a name with their mammalian counter parts; the distal segments, the distal early (DE) and the distal late (DL) – are homologous to the mammalian thick ascending limb (TAL) and distal convoluted tubule (DCT) respectively. We performed a chemical genetic screen using zebrafish embryos during nephrogenesis and analyzed the effects on segmental patterning.

Results: Interestingly, a large number of prostaglandin (Pg) pathway components were identified among our hits. Prostaglandins (Pgs) are fast-acting lipids necessary for an array of physiological functions. We discovered that treatment with bioactive Pg agonists restrict the PCT and DL, while inducing an expansion of the PST. Genetic knockdown and small molecule inhibition of the Pg producing Cox1/2 enzymes or the Pg Ep G-protein receptors triggered an expansion of the DE segment at the expense of the DL. Further, we saw that modifying levels of Pg pathway components significantly altered renal progenitor expression domains, including *sim1a* and *mecom*, which are required for normal proximal and distal tubule patterning, respectively.

Conclusions: Thus, we show here for the first time that Pg signaling has an impactful role in nephron cell-fate decisions, suggesting that Pgs may have considerable implications for therapeutic treatment of congenital kidney diseases as well as end-stage renal disease.

Funding: NIDDK Support, Other NIH Support - Office of the Director

FR-PO193

Cloning of the Zebrafish Kidney Mutant Zeppelin Reveals That Brca2/Fancd1 Is Essential for Renal Development Paul T. Kroeger, Rebecca A. Wingert. *Biological Sciences, Univ of Notre Dame, Notre Dame, IN.*

Background: Zebrafish kidneys are conserved with other vertebrates, making them an excellent genetic model to study renal development. The kidney collects metabolic waste using a blood filter with specialized epithelial cells known as podocytes. Podocyte formation is poorly understood but relevant to many kidney diseases, as podocyte injury leads to progressive scarring and organ failure.

Methods: *zeppelin (zep)* was isolated in a forward screen for kidney mutants and identified as a homozygous recessive lethal allele, which has a loss of podocyte numbers, deficient filtration, and fluid imbalance. Addition of retinoic acid did not rescue the *zep* mutant phenotype. Although mutants had normal proliferation and cell death, the interrenal gland was increased in size, suggesting a possible cell fate switch between these related lineages. This data was corroborated by interrenal gland volume identified by FISH analysis. 3β-HSD staining indicated the interrenal gland produced more hormones in the *zep* mutants, possibly suggesting an alternative mechanism of an endocrine feedback loop leading to overproliferation of interrenal cells.

Results: Meiotic mapping and whole genome sequencing of *zep* identified a splicing mutation in *breast cancer 2, early onset (brca2)/fancd1*, which was confirmed by sequencing of individual fish. Several independent *brca2* morpholinos phenocopied *zep*, causing edema and podocyte reductions, as well as an increase in the size of the interrenal gland. Additionally, 3β-HSD staining suggests that morphants have an increased number of cells that generate hormones, similar to *zep*. Histological analyses of the adult kidney in *zep* heterozygotes, brca2^{ZM_00075660} juveniles and adults showed renal pathologies associated with glomerular defects. Taken together, these data suggest for the first time that *brca2/fancd1* is essential for kidney development and homeostasis.

Conclusions: These findings impart novel insights into genetic components that impact kidney biology, and as Brca2/Fancd1 mutations cause Fanconi anemia and several common cancers, specifically breast and ovarian cancer in humans, this work has identified a new model to understand the role of Brca2/Fancd1 in disease.

Development of the Vasculature in the Bladder Julia K. Schaffer,[1] Kenneth A. Walker,[2] Caitlin M. Schaefer,[2] Daniel S. Bushnell,[2] Elina Mukherjee,[2] Sunder Sims-Lucas,[2] Carlton M. Bates.[2] *[1]Div of Newborn Medicine, Univ of Pittsburgh; [2]Div of Nephrology, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Developing bladder consists of differentiating outer muscle, middle stromal, and inner epithelial layers. To date, formation of the bladder vascular network has not been determined. Aim: To determine vascular patterning through bladder development.

Methods: We examined developing bladder vasculature from embryonic day (E) 11.5 through postnatal day (P) 30 by general histology and immunohistochemistry (including morphometry with GSL1 lectin staining). We performed quantitative realtime PCR (qPCR) for genes associated with vascular formation (e.g. Angiopoietin 1 and Vegfa ligands and Tie2 and Vegfr2 receptors) and hypoxia inducible factors (Hifs).

Results: In early bladder development (E11.5-13.5) vascular branches from the umbilical arteries grow towards a network of developing vessels within the primitive bladder mesenchyme. However, by E15.5, connections between the umbilical arteries and the maturing vascular network in the bladder are diminished, suggesting major vascular remodeling. Perfusion (presence of red blood cells) of most bladder vessels was identified even at early developmental time points. Morphometric assessment revealed a peak in relative vascular tissue content in the bladder at E15.5, which regressed with further maturation. This reduction in vascular content after E15.5 suggests vascular pruning and further remodeling. qPCR revealed that *Angpt1* and *Vegfr2* expression peaked during early embryonic development, whereas expression of the Angpt1 receptor, Tie2, peaked in early postnatal mice. The Vegfr2 ligand Vegfa displayed consistent expression at all ages. Interestingly, Hif1a and Hif2a demonstrate inverse mRNA expression profiles with Hif1a highest in embryonic bladders and Hif2a expression peaking in adult bladders.

Conclusions: Unexpectedly, bladder vasculature appears to arise from angiogenic vessels that arise from the umbilical artery. Subsequently, early bladder vessels undergo pruning with age. Key molecules that regulate vascular development, including hypoxia inducible factors, have differential expression patterns.

Exploring the Relation Between Cells and Extracellular Matrix in the Developing Human Fetal Kidney Astgik Petrosyan,[1] Estefanie Rodriguez,[1] Ruby Kim,[1] Hasmik Soloyan,[1] Brendan Grubbs,[2] Matthew Edward Thornton,[2] Roger E. De Filippo,[1] Laura Perin,[1] Stefano Da Sacco.[1] *[1]Urology, Children's Hospital Los Angeles, Los Angeles, CA; [2]Univ of Southern California.*

Background: It is widely accepted that, during development, the renal compartment undergoes dramatic changes in regards to cell specification and differentiation, matrix deposition and spatial organization. However, despite the growing number of studies focusing on kidney mouse development, very little is known of changes, including cell differentiation and extracellular matrix (ECM) deposition, occurring during human development. To fill this gap, we have characterized human embryonic kidneys (hEK) at different weeks of gestation to better understand renal progenitor biology and cell-matrix interactions.

Methods: Histological analysis were carried out on hEK between 11-22 weeks of gestation for ECM components (such as collagen IV a1-6 chains, collagen I, fibronectin) and progenitor/mature renal cells markers such as WT1, Pax-2, Six-2, Cited1, VE-Cadherin, a-SMA.

Results: We observed dynamic changes in the hEK throughout the progression of the gestational ages. In particular, decrease in nephrogenic zone size along with a higher presence of C- and S-shaped structures and fully developed glomeruli and tubules was confirmed in 19-22 week samples. Identification of progenitors or mature renal cells and fibrous proteins confirmed that ECM composition varies depending on the differentiation state of the surrounding cells. Collagen IV and fibronectin were absent in nephrogenic zone and condensing mesenchyme but found in C- and S-shaped bodies. In addition, Pdgfra (marker of cortical interstitial cells) was strongly expressed in the stromogenic zone and later restricted to the interstitium, co-localized with collagen I, suggesting a strong link between cell specification and matrix environment.

Conclusions: Our data suggest that, during hEK development, cell specification is accompanied by marked changes in ECM composition. This characterization might increase our knowledge of reparative processes enabling investigations focused on matrix remodeling and progenitor cell activation, thus ultimately enhancing the chances to treat renal damage.

Enalapril Treatment Modulates Lymphangiogenesis and Fibrogenic Machinery in the Developing Rat Kidney Kee Hwan Yoo, Hyung Eun Yim, In Sun Bae, Byungkwan Kim, Young Sook Hong, Joo Won Lee. *Dept of Pediatrics, Korea Univ Medical Center, Seoul, Republic of Korea.*

Background: The renin angiotensin system plays a pivotal role in both renal development and progressive renal disease.Lymphangiogenesis occurs during normal organ development and pathological processes. In this study, we aimed to investigate the effect of angiotensin II inhibition on the expression of fibrogenesis-related molecules and lymphatic vessels in the developing rat kidney.

Methods: Newborn rat pups were treated with enalapril (30 mg/kg) or vehicle for 7 days after birth. We investigated the intrarenal expression of fibroblast growth factor (FGF)-1, FGF-2, FGF receptor (R)-1, fibroblast-specific protein (FSP)-1, intercellular adhesion molecule-1, toll-like receptor (TLR)-2, and TLR-4 with Western blotting and immunohistochemistry at postnatal day 8. For the determination of lymphatics, the lymphatic vessel markers of vascular endothelial growth factor (VEGF)-C, VEGFR-3, and podoplanin were assessed. For the detection of cell proliferation and collagen fibers, Ki-67 and Sirius red stainings were performed.

Results: In the enalapril-treated group, intrarenal FGF-1, FGF-2, FGFR-1 and VEGF-C protein expression were decreased, compared to the controls ($P < 0.05$). Immunohistochemistry for the lymphatic vessel markers of VEGF-C, VEGFR-3, and podoplanin showed reduced lymphatic immunostainings in the enalapril-treated kidneys. However, FSP-1 expression was prominent in the interstitium and glomeruli in enalapril-treated kidneys. While cell proliferation was reduced in the enalapril-treated group, collagen deposition was enhanced in the enalapril-treated kidneys ($P < 0.05$). Intercellular adhesion molecule-1, TLR-2, and TLR-4 protein expression showed no differences between the two groups.

Conclusions: Enalapril treatment during postnatal 7 days may induce perturbations in FGF/FGFR signals, cell proliferation, and lymphangiogenesis required for renal development and maturation and activate in part the fibrogenic machinery in the developing rat kidney.

FR-PO197

The Effect of Prenatal Hypoxia and a Postnatal High Salt Diet on Renal Structure in the Aged Mouse Sarah L. Walton,[1] Reetu R. Singh,[2] Joan Li,[3] Helle Bielefeldt-Ohmann,[4] Tamara Paravicini,[1] Melissa H. Little,[3] Karen M. Moritz.[1] *[1]School of Biomedical Sciences, Univ of Queensland, Brisbane, Queensland, Australia; [2]Dept of Physiology, Monash Univ, Melbourne, Victoria, Australia; [3]Inst for Molecular Bioscience, Univ of Queensland, Brisbane, Queensland, Australia; [4]School of Veterinary Science, Univ of Queensland, Gatton, Queensland, Australia.*

Background: Chronic fetal hypoxia leads to growth restriction and increased risk of adulthood disease. This study examined the long-term renal outcomes of offspring prenatally exposed to hypoxia, and whether a postnatal high salt diet could exacerbate impairments.

Methods: Pregnant CD1 mice were housed in a hypoxic chamber (12.0% O_2; N=8, HYP) or control (21% O_2; N=8, CON) environment from embryonic day (E) 14.5 to birth (E19.5). A subset of male offspring was randomly allocated to a control diet (0.2% NaCl; NS) or high-salt diet (5% NaCl; HS) from 10 weeks of age. Blood pressure was measured at 12 months of age and kidneys were collected. Kidney sections were examined for nephron number, glomerulosclerosis, interstitial fibrosis, renal vascular remodeling, and alpha-smooth muscle actin (α-SMA) expression by a researcher blinded to treatment groups.

Results: Prenatal hypoxia led to a decrease in nephron number and elevated blood pressure. Kidneys of HYP offspring showed expansion of the mesangial matrix, thickening of glomerular basement membranes and increased glomerulosclerosis compared to CON. These changes were exacerbated by the HS diet. Interstitial fibrosis and renal vascular remodeling scores were increased in CON and HYP offspring fed the HS diet, with the effect greatest in HYP offspring. α-SMA staining of CON kidneys was confined to vascular smooth muscle cells; however, aberrant glomerular and interstitial α-SMA staining was observed in CON offspring fed the HS diet and HYP offspring fed NS and HS diets.

Conclusions: Prenatal hypoxia led to reduced nephron number and pathological renal abnormalities, likely contributing to elevated blood pressure. The combination of prenatal hypoxia and a postnatal high salt diet significantly exacerbated renal abnormalities and signs of injury.

Folic Acid Alleviates Reduced Ureteric Branching and Nephrogenesis Induced by Maternal Undernutrition in Rat Embryonic Kidney Midori Awazu, Mariko Hida. *Dept of Pediatrics, Keio Univ School of Medicine, Tokyo, Japan.*

Background: We reported that maternal undernutrition reduces nephron number, ureteric branching, and global DNA methylation. Also, blockade of DNA methyltransfarase 1, which maintains DNA methylation, inhibited ureteric branching in organ culture. Since the supplementation of folic acid (FA), a methyl-group donor, ameliorates hypertension due to maternal low protein diet, we examined whether FA rescues the kidney developmental defects induced by maternal undernutrition.

Methods: The kidneys of embryonic day 14 and 18 (E14 and E18) fetuses from dams given food ad libitum (CON), those subjected to 50% food restriction throughout pregnancy (NR), and NR supplemented with FA 5 mg/kg (NRFA) were examined (n=3-7 litters). Ureteric buds were visualized by pancytokeratin staining. DNA methylation was assessed by methylated DNA quantification kit. E13 metanephroi from normal rats were subjected to organ culture in DMEM with or without FA 8 μg/ml for 3 days.

Results: Maternal undernutrition significantly reduced fetal body weight (0.143±0.004 vs 0.173±0.003 g), kidney surface area (2.4±0.3 vs 3.8±0.5), and ureteric tip number (4.0±0.4 vs 8.5±0.8) at E14. FA supplementation did not affect body weight (0.147±0.003 g) or kidney surface area (2.2±0.4), but restored ureteric tip number (7.0±0.7, P<0.05 vs NR). At E18, FA supplementation again did not affect body weight (1.28±0.02 vs NR: 1.24±0.05 g) or kidney weight (6.1±0.8 vs NR: 5.5±0.4 mg). FA, however, partially restored the glomerular density (15.6±2.7/mm^2, P<0.05 vs NR) that was significantly lower in NR (10.3±0.9) than CON (20.2±3.7). DNA methylation of NR was significantly reduced in NR (8.7±1.1%) vs CON (29.8±5.6%) at E18. IN NRFA, DNA methylation was partially restored to 20%. In the metanephroi cultured under FA deficiency, the ureteric tip number was significantly reduced (6.6±0.3, n=10) vs controls (9.9±0.9, n=7). The kidney surface area was also significantly reduced by FA deficiency (3.0±0.2 vs 3.8±0.2).

Conclusions: FA is needed for the metanephric development, and its supplementation alleviates the reduced ureteric branching and nephrogenesis in the offspring of nutrient restricted rats probably by restoring DNA methylation.

A Perinatal Switch in Iron Utilization Determines Postnatal Chronic Kidney Disease Rongjia Deng,[1] Rosemary V. Sampogna,[1] Andong Qiu,[1,2] Jonathan M. Barasch.[1] *[1]Columbia Univ; [2]Tongji Univ, China.*

Background: Iron deficiency affects 2 billion people world-wide and is a threat to embryonic and early postnatal development. Periconceptual maternal iron deficiency (PM-ID) results in hypoplastic postnatal kidneys but it is not clear whether PM-ID causes cell-lineage or cell-stage specific hypoplasia, nor which species of iron is involved.

Methods: We investigated a mouse model of dietary iron deficiency and a series of deletions of the transferrin receptor,TfR1 (cell autonomous transferrin iron deficiency, ATF-ID) in different cellular lineages using a novel TfR1-floxed construct.

Results: Severe PM-ID depleted both Tf iron and NTBI (non-transferrin bound iron) resulting in severely hypoplastic proximal tubules and even anephria during gestation, whereas the overall structure of ureteric bud was maintained. Milder PM-ID resulted in surviving but severe postnatal kidney hypoplasia, disruption of the growth of the proximal tubule and TALH and increased mortality before weaning. To determine the mechanism of hypoplasia we examined mesenchymal, ureteric and stromal ATF-ID with different Cre drivers. Mesenchymal ATF-ID (Six2Cre or KspCre) demonstrated increasing demand for transferrin by the time of birth, resulting in worsening proximal tubule hypoplasia, remarkable cystic transformation and interstitial fibrosis, and even anephria (ProPax3Cre) after birth, the timing of which coincided with accelerated segment-specific growth. The combination of ATF-ID and PM-ID further worsened nephron development. In contrast, the collecting ducts (HoxB7Cre) and stroma (Foxd1Cre) did not depend on transferrin.

Conclusions: In sum, NTBI supported prenatal and postnatal stromal and ureteric development and the initial stages of metanephric development, whereas Tf iron was required for perinatal maturation of the nephron. Tf-iron depletion resulted in hypoplasia, cysts, and fibrosis, the timing and specificity of which was the result of a sequence of utilization of NTBI followed by Tf-iron. We propose that a peri-natal switch in the mechanisms of iron utilization accompanies the compartmentalization of the kidney and reflects changing cellular control of iron delivery. Iron deficiency is a cause of CKD.

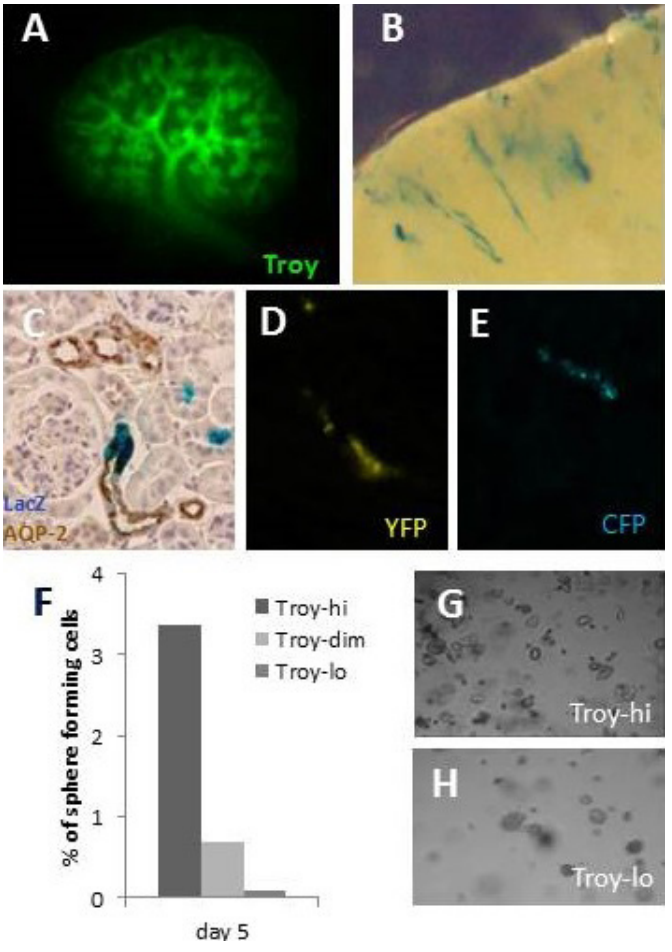
Troy/TNFRSF19 Marks a Progenitor/Stem Cell Population in the Kidney Frans Schutgens,[1,2] Maarten B. Rookmaaker,[1] Robert Vries,[2] Marianne C. Verhaar,[1] Hans Clevers.[2] *[1]Nephrology and Hypertension, UMC Utrecht, Utrecht, Netherlands; [2]Hubrecht Inst, Utrecht, Netherlands.*

Background: Segment committed stem cells play a crucial role in renal development and regeneration. Identification of these stem cells is an important step towards the development of new diagnostic and therapeutic strategies for renal diseases. In this study, we evaluated Troy, an adult stem cell marker in other organs, as a marker for segment committed stem cells in the developing and adult kidney.

Methods: Renal Troy expression was assessed during embryonic development and adult turnover using Troy-GFP mice. The contribution of Troy+ cells to renal development and turnover was investigated using *in vivo* lineage tracing in Troy-GFP-CreERT2;Rosa-LacZ mice and the clonality of this contribution in Troy-GFP-CreERT2;Rosa-4color mice. Tracing was induced during or after cessation of nephrogenesis (p1 or p35) by tamoxifen injection. Daughter cells were identified using immunohistochemistry for tubular segment-specific markers. In addition, *in vitro* stem cell capacity was assessed by a sphere-forming assay.

Results: During embryonic development Troy+ cells were present in the ureteric bud [1A], whereas in adult kidney Troy+ cells were present in the papilla. After p1 induction, Troy+ cells gave rise to tubular structures by clonal expansion that persisted up to 2 years after induction [1B-1E]. Immunohistochemistry revealed predominant co-staining with collecting duct marker AQP2 [1C]. Troy+ cells continued to contribute to collecting duct formation after cessation of nephrogenesis. Finally, Troy^{hi} cells had a higher *in vitro* sphere forming capacity than Troy^{dim} and Troy^{lo} cells [1F-1H].



Conclusions: These data show that Troy marks a stem/progenitor population for the collecting duct in the developing kidney. Moreover, our data also suggest a role for Troy+ progenitor cells in the adult kidney.

Preserved Nephrogenesis following Partial Nephrectomy in Early Neonates Yuhei Kirita,[1] Daisuke Kami,[2] Ryo Ishida,[1] Tetsuro Kusaba,[1] Takaomi Adachi,[1] Satoshi Gojo.[2] *[1]Nephrology, Graduate School of Medical Science, Kyoto Prefectural Univ of Medicine, Kyoto, Japan; [2]Regenerative Medicine, Graduate School of Medical Science, Kyoto Prefectural Univ of Medicine, Kyoto, Japan.*

Background: For a long time, although the appendage regeneration has been limited to non-mammalian vertebrates, the rodent neonates demonstrated the capability to regenerate the resected cardiac apex. In this study, we hypothesized that neonatal kidney could maintain the capability of neonephrogenesis.

Methods: One sixth-partial resection at the inferior pole of right kidney was performed on neonatal rats at postnatal day 1 (P1) and day 4 (P4) under the hypothermic anesthesia. The animals were sacrificed with time to examine by pathology and quantitative PCR, including key transcription factors, cytokines, and signaling molecules related to nephrogenesis, whether the resected portions were regenerated, or not.

Results: The pathological findings in nephrectomized kidney on P1 (P1X-kidney) seemed to bulge the newly formed cortex from the edge of the wound with the minimum inflammations, on the contrary, the inflammations was prominent in nephrectomized kidney on P4 (P4X-kidney). Immunohistochemistry in P1X-kidney demonstrated the preservation of the nephron number and the cortex area 28 days post-resection. On the other hand, P4X-kidney showed that those significantly decreased. Numerous apoptosis and sparse cell proliferation were significantly recognized in P4X-kidney, and P1X-kidney expressed the opposite findings. An array of quantitative PCR postulated the implication of Six2 expression to those differences between P1 and P4 kidney following the partial nephrectomy. The Six2 expression was reinforced in P1X-kidney more than age matched control kidney, whereas it had already gone in P4X-kidney.

Conclusions: Our results indicate that rat kidney maintains the capability to generate new nephrons in early neonates. Neonatal period could offer the unique model to study the regenerative or reparative phenomena.

FR-PO202

BrdU Labeling Adult Renal Stem Cells in Development Kidney Li Ni, Jing Chen. *Nephrology, Huashan Hospital, Shanghai Medical College, Fudan Univ, Shanghai, China.*

Background: The labeling-retaining cell (LRC) approach is a reliable way to identify adult stem cells.To identify the best labeling time for adult renal stem cells,we administered BrdU in different periods of the kidney development.

Methods: A pulse of BrdU was administered at different periods during E11.5-20.5, respectively, covering the whole process of the kidney development.The adult kidney were examined the distribution of BrdU-positive cells.A subtotal nephrectomy(Nx) was induced in adult mice to observe the response of BrdU-retaining cells to injury.

Results: In adult kidneys,the distribution of BrdU-retaining cells was heterogeneous with different BrdU-labeling time.With BrdU labeled at E11.5-13.5,lots of BrdU-positive cells were located in the papilla and inner medulla,only few scattered in the proximal tubules.With BrdU labeled at P0.5-2.5,lots of cells in the inner medulla and outer medulla could retain the immunoreactivity of BrdU.With BrdU labeled at P3.5-5.5,P6.5-8.5,or P9.5-11.5,the distribution of BrdU-positive cells was mainly in the outer medulla,few in the cortex inner medulla,no longer in the papilla.With BrdU labeled at P12.5-14.5 and P15.5-17.5,lots of BrdU-positive cells were in the outer medulla,but no longer in the papilla or inner medulla.With BrdU labeled at P18.5-21.5,BrdU-positive cells were only found in the cortex.The proximal tubules were the only nephron segments stably containing few BrdU-retaining cells after a chase period of six months.After Nx in adult mice,BrdU-positive cells were more significantly increased in the cortex near the incision edge.BrdU-positive cells mainly distributed in the proximal tubules at the site of injury.Some BrdU-positive cells did not express PCNA,even though numerous PCNA-positive cells were found near the incision edge of kidney.In contrast,originally retained abundant BrdU-positive cells in the outer medulla and inner medulla significantly reduced and disappeared rapidly in the vicinity of incision.

Conclusions: The locations of LRCs were different if BrdU was administered in different periods of kidney development.Most of BrdU-retaining cells were quiescent,few of them in the proximal tubule and papilla may be the renal progenitor cells.

FR-PO203

Tissue-Specific Transport and Injury Response in Kidney Tubules Derived from Human Pluripotent Stem Cells Benjamin S. Freedman,[1,2,3] Craig R. Brooks,[1,2] Albert Q. Lam,[1,2] Ryuji Morizane,[1,2] Joseph V. Bonventre.[1,2] *[1]Brigham and Women's Hospital; [2]Harvard Medical School; [3]Univ of Washington School of Medicine.*

Background: Human pluripotent stem cells (hPSCs) can differentiate into cells expressing markers of kidney proximal tubules, but the functional capacity of these structures remains poorly understood. We developed a new, adherent, 3D culture system to evaluate transport and injury characteristics in hPSC-derived kidney tubules, compared to undifferentiated hPSCs.

Methods: hPSCs sandwiched in extracellular matrix were maintained in pluripotency-sustaining media to form undifferentiated cavitated spheroids ($SOX2^+OCT4^+$), or differentiated with growth factors into nephron progenitor cells ($PAX2^+SIX2^+$) and subsequently proximal tubules (LTL^+LRP2^+). hPSC spheroids or differentiated tubules were incubated with small molecule fluorescent probes to monitor transport into lumens, or with nephrotoxic chemicals to assess upregulation of kidney injury molecule-1 (KIM-1).

Results: Kidney tubule lumens selectively accumulated rhodamine-dextran (RD) and fluorescein methotrexate (MTX) transport cargoes. Inhibition of actin polymerization with Latrunculin B, or permeabilization of tight junctions with EDTA, significantly reduced cargo accumulation. When treated with the nephrotoxic compounds gentamicin or cisplatin, ~ 70 % of hPSC-derived proximal tubules expressed KIM-1 at the apical/luminal surface. In contrast, the lumens of undifferentiated hPSC spheroids did not accumulate RD and MTX, nor express KIM-1 after toxic injury with cisplatin or gentamicin.

Conclusions: hPSC-derived kidney tubules are capable of transport and injury responses, which are characteristic of kidney proximal tubules and distinct from undifferentiated hPSC epithelia. The accessibility of this system to small molecules and live-cell microscopy enables rapid and real-time visualization of transport processes and testing of molecular pathways. KIM-1 expression in hPSC-derived kidney tubules may provide a quantifiable standard with which to predict human nephrotoxicity. Our findings introduce a framework in which to evaluate the functionality of hPSC-derived kidney epithelia, prior to transplantation into ESRD patients.

FR-PO204

Progress in the Development of Human iPSC Derived Proximal Tubule-Like Cells for Drug Toxicity Screening Anja Wilmes, Georg Kern, Caroline Rauch, Gerhard Gstraunthaler, Paul Jennings. *Dept of Physiology, Medical Univ of Innsbruck, Innsbruck, Tirol, Austria.*

Background: Nephrotoxin exposure can initiate acute kidney disease and accelerate the progression of chronic kidney disease. The proximal tubule is a frequent target as it transports a wide variety of chemical entities, some of which can cause tubular injury. Primary cell culture and cell lines have been used successfully to investigate molecular mechanisms of chemical toxicity. However, there are several disadvantages of traditional cell culture, including limited tissue availability, phenotypic alterations due to immortalisation and a lack of genetic diversity. With the dawn of induced pluripotent stem cell (iPSC) technology,

many of these disadvantages could potentially be overcome. To this end we have been attempting to develop a protocol to produce proximal tubule-like cells from human iPSCs with xenobiotic transport capabilities.

Methods: Human iPSCs were differentiated into the intermediate mesoderm (IM) using Wnt and retinoic acid activation (CHIR99021 and TTNBP). Cells were further differentiated using combinations of different growth factors.

Results: The derived cells exhibit cobble stone morphology and express certain proximal tubule proteins such as claudin-2. Additionally, the cells can be maintained for up to 4 weeks in culture. Preliminary results demonstrate the ability of the differentiated cells to take up organic cations (4-Di-10-ASP) and organic anions (6-CF) and to extrude p-glycoprotein substrates (calcein-AM).

Conclusions: While further characterization will be needed, the initial results are promising, indicating that proximal tubule-like cells derived from iPSCs could be a new tool for screening the nephrotoxic potential of compounds.

Funding: Private Foundation Support, Government Support - Non-U.S.

The Direct Differentiation Method of Renal Tubular Cells by Synthetic mRNAs of Transcription Factors Identified from TF-Inducible Human ES Bank Ken Hiratsuka,[1] Toshiaki Monkawa,[1] Shintaro Yamaguchi,[1] Ryuji Morizane,[1] Shigeru B.h. Ko,[2] Minoru S.h. Ko,[2] Hiroshi Itoh.[1] *[1]Dept of Internal Medicine, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan; [2]Dept of System Medicine, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan.*

Background: To find transcription factors which promote differentiation towards renal tubular cells, we utilize the human ES lines with doxycycline-controllable transcription factors (TF-inducible hES bank). To establish the differentiation method of renal tubular cells, we transfect the synthetic human mRNA of the target transcriptional factors into human ES cells.

Methods: We performed exhaustive search for DNA microarray data after TF induction in the hES bank, and analyzed them in silico to find the specific transcription factors, which expressed in kidney epithelial cells. We synthesized the synthetic human mRNA of the target transcription factors. By using the lipofection method, we transfected the synthetic mRNA of target transcription factors to human ES cells, and cultured them. The morphological changes, mRNA expressions, and protein expressions were analyzed.

Results: Some candidate transcription factors, which expressed in human kidney epithelial cells, were identified by in silico analysis. We successfully made synthetic mRNA of candidates of transcription factors. Five days after the transfection of the synthetic mRNA to human ES cells, we were able to observe characteristic morphological changes in the differentiated cells. The mRNA expression of OSR1, ITGA8, AQP1, and MEGALIN were increased. Moreover, the protein expression of AQP1 and LTL were also detected in the differentiated cells.

Conclusions: We identified specific transcription factors for differentiation toward kidney (especially, proximal tubular cells) , and demonstrated that the differentiation of proximal tubular cell phenotype from human ES cells by a novel method using synthetic mRNA.

FR-PO206

Differentiation of Human iPSC into Functional Podocytes Caroline Rauch,[1] Anja Wilmes,[1] Elisabeth Feifel,[1] Georg Kern,[1] Paul Jennings,[1] Gerhard Gstraunthaler.[1] *[1]Innsbruck Medical Univ; [2]Innsbruck Medical Univ; [3]Innsbruck Medical Univ; [4]Innsbruck Medical Univ.*

Background: Podocyte injury and subsequent loss of glomerular integrity is a major cause for chronic kidney disease (CKD). Two-thirds of patients with CKD suffer from disorders that arise from the glomerulus, mainly due to podocyte injury. Podocytes are highly specialized cells with a complex cytoarchitecture composed of foot processes that form the glomerular filtration barrier. The study of the molecular processes of glomerular injury is hampered by the fact that cultured primary podocytes have a limited capacity to divide and are difficult to maintain. However, generation of pluripotent stem cells (induced PSCs) from somatic cells allows the possibility of a new source of human cells. The high differentiation capacity of iPSCs would potentially enable the establishment of differentiation protocols for iPSC-derived podocytes which can overcome the burden of primary podocytes in culture.

Methods: To this end we applied and optimized a previously published protocol for podocyte differentiation (Song et al., 2012; PMID: 23029522). Human iPSCs are grown in differentiation media for ten days, containing growth factors known to be important for *in vivo* podocyte differentiation, BMP-7, activin A, and retinoic acid. Conditionally immortalized human podocyte cultures served as controls.

Results: After three days in differentiation media, iPSCs showed a clear podocyte morphology with podocyte foot processes. To further prove the state of podocyte differentiation, expression of specific podocyte markers was examined via immunofluorescence. Marked expression of the podocyte specific markers podocin and synaptopodin could be successfully verified on differentiated iPSCs. In addition, iPSC-derived podocytes showed significant release of VEGF into the culture medium. Finally, doxorubicin, a podocyte specific toxin, was highly toxic to these cells with an IC50 of 1μM after 48h.

Conclusions: Podocytes generated from iPSCs have far reaching applications in disease modelling, tissue engineering, drug screening and discovery, and toxicity testing.

Sourcing of Renal Tubular Epithelial Cells from Human Stem Cell-Derived Kidney Organoids Elijah Weber,[1] Benjamin S. Freedman,[2] Jonathan Himmelfarb,[3] Edward J. Kelly.[1] *[1]Pharmaceutics, Univ of Washington, Seattle, WA; [2]Nephrology, Univ of Washington, Seattle, WA; [3]Kidney Research Inst, Univ of Washington, Seattle, WA.*

Background: Human pluripotent stem cells (hPSCs) provide a self-renewing, reproducible source of kidney cells for laboratory investigation and regenerative medicine approaches. We tested the potential of hPSC-derived renal tubular epithelial cells (RTECs) to grow and maintain differentiation in 2D and 3D cultures, compared to primary RTECs from adult kidneys.

Methods: hPSCs were treated with growth factors to promote differentiation into nephron progenitor cells ($PAX2^+SIX2^+$) and subsequently proximal tubules ($LTL^+ZO1^+LRP2^+$). RTECs purified from tubular organoids were re-plated on tissue culture plates with or without extracellular matrix. RTECs were analyzed for proliferation, kidney-specific marker expression, and their capacity to seed a 'kidney on a chip' 3D microphysiological system (MPS).

Results: RTECs purified from hPSC organoids grew to confluent monolayers in minimal RTEC growth media on extracellular matrix. hPSC-derived RTECs resembled primary RTECs morphologically. Marker immunofluorescence analysis revealed that purified hPSC-RTECs possessed $ZO1^+$ tight junctions and reacted with LTL. Sub-cultivation was limited to 2-3 passages, after which hPSC-RTECs underwent epithelial-to-mesenchymal transition and senesced. In a 3D MPS, hPSC-derived RTECs formed tubular structures comparable to primary RTECs. Immunofluorescence staining demonstrated positive signals for the tubule transporters SGLT2 and OAT3 as well as the epithelial markers CD13 and E-cadherin.

Conclusions: We have shown that hPSC-RTECs can propagate *in vitro* and maintain their differentiated characteristics, with morphology and markers similar to primary RTECs. When hPSC-RTECs are grown in a 3D MPS, they maintain an epithelial phenotype and express membrane transporters essential for functions including glucose reabsorption and organic anion secretion. This system establishes a platform in which to optimize hPSC-RTEC expansion and function in a 3D, microfluidic context, with relevance for human disease modeling *in vitro* and bioengineering of regenerative therapeutics.

FR-PO208

Genome-Wide Methylation Analysis of Epigenetic Memory in Human Kidney Derived iPS Cells Osamu Takase, Taro Tsujimura, Masaomi Nangaku, Keiichi Hishikawa. *Dept of Advanced Nephrology and Regenerative Medicine, The Univ of Tokyo, Tokyo, Japan.*

Background: Epigenetic memory such as DNA methylation signature of iPS cells derived from parental cells was reported to determine the differentiation fate of the iPS cells (Nature 2012). Last year, we reported the result of kidney specific induction protocol (Nature Commun, 2013) by using two different kinds of human iPS cells established from human fibroblast (F-iPS) and human kidney epithelial cells (K-iPS), and demonstrated more efficient induction of markers of kidney development (WT-1, Pax-1, Sall-1) and differentiation (AQP-1, Nephrin) in K-iPS as compared with F-iPS cells.

Methods: In this study, we performed a genome-wide methylation analysis of K-iPS and F-iPS cells, and tried to clarify the mechanism of kidney lineage specific induction of human iPS cells.

Results: Among 27,578 sites, we focused on high CpG promoter lesion (GC>0.55, CpG>0.75). 56 genes such as Kid1 and SOD2 were strongly methylated in F-iPS than in R-iPS. 17 genes such as KCNK12 and GATA4 were strongly methylated in R-iPS than in F-iPS. The markers of kidney development were strongly methylated in F-iPS than in K-iPS cells (Pax-2; 23.6 vs 2.1, Sall-1; 28.7 vs 4.3). However, the marker of differentiation was strongly methylated in K-iPS (AQP-1; 1.7 vs 1.1).

Conclusions: These results demonstrate that epigenetic memory in parental cell determine the induction of human iPS cells toward kidney lineages, and the role of key genes in kidney lineage specific induction will be discussed.

Mechanism of Kidney Repair in the Omentum-Kidney Model – Tubulogenesis and Differentiation of Free-Lying WT-1 Cells to Podocytes Occurring in the Fusion Zone Ignacio Garcia-Gomez,[1,3] Krishnamurthy P. Gudehithlu,[2] Peter D. Hart,[1,2,4] Jose A.L. Arruda,[1,3] Ashok K. Singh.[1,2,3] *[1]Hektoen Inst of Medicine, Chicago, IL; [2]Div of Nephrology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL; [3]Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL; [4]Internal Medicine, Rush Univ Medical College, Chicago, IL.*

Background: When activated omentum was fused to the injured kidney it induced glomerular repair and ameliorated chronic kidney disease (Garcia-Gomez et al JASN 2014). The fusion zone between the omentum and the injured kidney was highly proliferative (high Brdu uptake), with abundant free-lying nephron progenitor WT-1 cells. In this study, we examined the fusion area to further understand the mechanisms of repair in this model.

Methods: In 5/6 surgically nephrectomized rats polydextran gel was introduced intraperitoneally to activate the omentum and fuse to the injured kidney. Nephrectomized rats with complete omentectomy were used as control. Kidney tissues were examined 1- 3 weeks after injury by histology and immunofluorescence (Pax-2, WT-1 and podocalyxin).

E15 embryonic rat kidney served as control for immune-staining. Two-week fusion zone tissue and tissue far from fusion zone, control and normal was quantified for mRNA for selected developmental genes (WT-1, Wnt-4, Pod1, Lim1, HNF-6, BMP-7) by RT-PCR.

Results: We found that the fusion zone tissue showed proliferation and expansion of collecting ducts, as evidenced by intense staining for Pax2, in a pattern similar to that seen in E15 embryonic rat kidney. Further, several islands of WT-1 cells in the fusion zone differentiated to podocytes, as judged by co-expression of podocalyxin. mRNA for Wnt-4 and WT-1 increased by 10-20 folds and mRNAs for other developmental genes increased by 2-5 folds in the fusion zone. Control tissue did not show the above changes.

Conclusions: The fusion zone tissue between the injured kidney and omentum appears to be a highly active tissue with proliferation and differentiation of kidney progenitor cells (WT-1, Pax-2, podocalyxin) taking place, and thus providing a healing environment to the injured kidney.

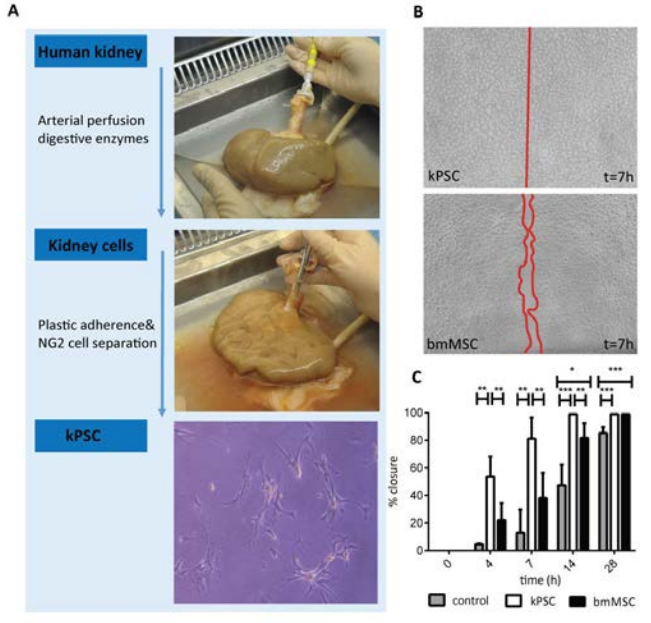
Transcriptional and Functional Characterization of Clinical Grade Isolated Human Kidney Derived Perivascular Stromal Cells Danielle Leuning, Marlies Reinders, Ellen Lievers, Cees van Kooten, Marten A. Engelse, Ton J. Rabelink. *Nephrology, LUMC, Netherlands.*

Background: Mesenchymal stromal cells (MSCs) are immunomodulatory cells and have shown beneficial effects in kidney disease. It has previously been shown that human perivascular stromal cells (PSCs) from several different organs share characteristics of bone marrow derived MSCs (bmMSC), however, at the same time there are tissue specific properties. We hypothesized that human kidney derived PSCs (hkPSCs) are, due to tissue specific imprinting, more potent in kidney repair compared to bmMSCs and sought to find a novel clinical grade isolation method.

Methods: Human transplantation grade kidneys (n=3) were digested with continuously circulating proteolytic enzymes. The resulting crude cell suspension was cultured in αMEM 5% platelet lysates and cells were selected for plastic attachment and NG2 cell enrichment (fig A). Culture was continued until spindle shaped cells appeared (kPSCs) and were compared to bmMSCs between passages 5-10.

Results: hkPSCs have comparable marker expression, cytokine excretion patterns, vascular stabilization and immunosuppressive capacity compared to bmMSCs. hkPSCs showed a distinct gene expression profile including an increased expression of HoxD11, a homeobox factor important in nephrogenesis. In a wound scratch assay, kidney epithelial wound healing with conditioned medium of hkPSCs was significantly faster and after 7 hours approx. 80% closure was seen with hkPSC conditioned medium, which was only 40% with bmMSC supernatant ($p<0.01$) (fig B, C).



Conclusions: Here we show a novel, clinical grade isolation method of hkPSCs and compared these cells to bmMSCs. hkPSCs showed a distinct expression profile and are able to enhance kidney tubular epithelial wound healing to a greater extent than bmMSCs. Therefore hkPSCs are a promising new cell therapeutic candidate to explore for treatment of kidney disease.

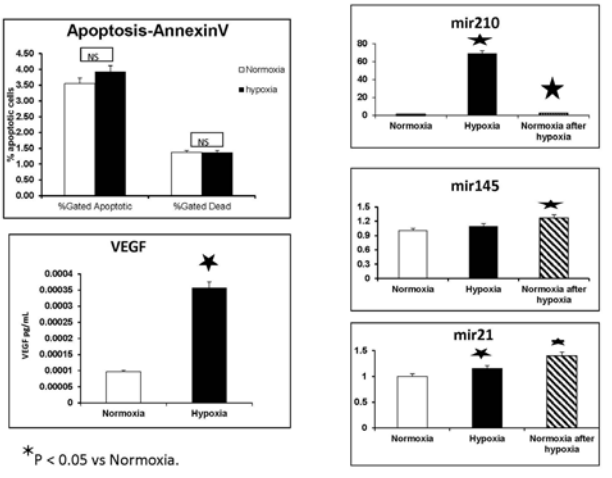
Functional Alterations of Adipose-Derived Mesenchymal Stem Cells from Human with Atherosclerotic Renovascular Disease Under Hypoxic Conditions Ahmed Saad, Allan B. Dietz, Sandra Herrmann, Alfonso Eirin, Abdelrahman Abdallah Abohashem Aly, Hui Tang, Soon Hyo Kwon, Kyra L. Jordan, John R. Woollard, Joseph P. Grande, Lilach O. Lerman, Stephen C. Textor. *Mayo Clinic.*

Background: Atherosclerotic renal vascular disease (ARVD) induces microvascular loss and interstitial inflammation, ultimately leading to ischemic injury. Mesenchymal stem cells (MSCs) can induce angiogenesis, decrease inflammation, and limit apoptosis in experimental animals. Aging and co-morbid conditions may blunt these properties in older human subjects. This study tested the hypothesis that hypoxic preconditioning of adipose tissue-derived MSCs would modify expression of MicroRNAs (miR) associated with MSCs survival, angiogenic, and anti-inflammatory properties.

Methods: MSCs obtained from subcutaneous tissue of 7 patients with ARVD (Age 75.3±4) were cultured under normoxic or hypoxic conditions (1% O_2) for 4 days. Hypoxic MSCs were returned to normoxia thereafter. Levels of the pro-survival and pro-angiogenic factors vascular endothelial growth factor (VEGF) and insulin-like growth factor (IGF) were measured in the supernatant by ELISA. Expression of MiRs- 210, 21 and 145 in MSCs was measured by quantitative rt-PCR and apoptosis by flow cytometry for Annexin V.

Results: Hypoxic conditions increased VEGF and IGF ($p<0.05$) in MSC supernatant, but had no effect on apoptotis.



*P < 0.05 vs Normoxia.

MiR-210 rose more than 68 fold in hypoxic MSCs over control conditions ($p<0.0001$), and reversed when returned to normoxia. Levels of miR-21 and 145 rose in hypoxic MSCs ($p<0.05$) and remained so after restoring normoxic conditions.

Conclusions: Hypoxia augmented angiogenic cytokine secretion and both reversible (miR-210) and irreversible (miR-21 and miR-145) micro-RNA expression in MSC from older human subjects with ARVD. These data support a potential role for hypoxic preconditioning to enhance the angiogenic potency of MSCs in humans with ARVD.

FR-PO212

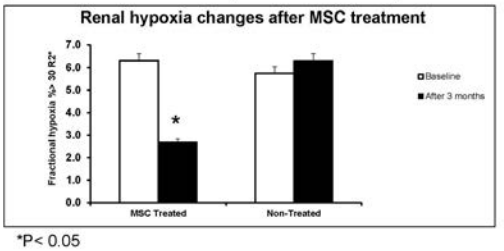
Safety of Intra-Arterial Autologous Adipose-Derived Mesenchymal Stem Cells in Human Atherosclerotic Renovascular Disease Ahmed Saad, Sandra Herrmann, Michael A. Mckusick, Sanjay Misra, James Glockner, Alfonso Eirin, Joseph P. Grande, Allan B. Dietz, Lilach O. Lerman, Stephen C. Textor. *Mayo Clinic.*

Background: Atherosclerotic Renovascular disease (ARVD) reduces blood flow (RBF) and GFR, and amplifies kidney hypoxia and inflammation. Adipose-derived mesenchymal stem cells (aMSCs) improve renal function in swine ARVD, in part by improving cortical micro-vascularization, but their safety and efficacy in humans are unknown. We report initial results from a pilot study of unilateral intra-arterial administration of low dose of autologous aMSCs in human subjects with ARVD under an FDA-approved IND.

Methods: Seven patients (Age 75.3±4) with severe ARVD were studied during fixed Na+ diet and ACE/ARB Rx before and 3 months after unilateral arterial injection of $2x10^5$ autologous aMSCs/kg. Stenotic-kidney (SK) cortical and medullary perfusion, volume and RBF were measured using multidetector CT and GFR by iothalamate clearance. SK deoxyhemoglobin levels (R2*) and fractional hypoxia were measured by 3T BOLD-MRI. Renal vein levels of neutrophil gelatinase-associated lipocalin (NGAL), monocyte chemotactic protein-1 (MCP-1), and tumor necrosis factor (TNF-α) were also measured.

Results: All patients tolerated aMSC without adverse effects. SK cortical volume and whole kidney RBF increased after three months (Figure 1), as did measures of tissue oxygenation, whereas no changes observed in the contralateral untreated kidneys (CLK) (data not shown). SK GFR did not change, nor did renal vein levels of TNF- α, MCP-1, or NGAL.

SK N=7	Baseline	After 3 months	P-value
Cortical Kidney volume (CT) mL	49.9 ± 22.4	54.7 ±25.4	**0.03**
RBF(ml/min)	115.1 ± 74.4	135.2 ± 96.5	**0.05**
TNF-α (pg/mL)	8.5 ± 2.1	10.3± 2.8	0.2
MCP-1 (pg/mL)	577.5 ± 169.7	573.3 ± 103.04	0.5
NGAL (ng/mL)	226.4 ± 32.9	247.3 ± 28.1	0.18
Cortical R2* (1/Sec)	18.7 ± 2.1	16.9 ± 2.5	**0.01**
Kidney hypoxia (% R2*> 20/sec)	41.8 ± 18.02	35.8 ± 15.3	**0.05**
GFR(ml/min/1.73m²)	14.6 ± 8.1	14 ± 7.2	0.2



*P< 0.05

Conclusions: Intra-arterial autologous aMSCs were tolerated with no adverse effects. This low dose, delivered without renal revascularization, was associated with increased tissue oxygenation and cortical RBF, consistent with improved renal microcirculation. Our results provide first-in-humans evidence to support a role for aMSC to restore local blood flow and oxygenation in ARVD.

Cell Therapy with Serelaxin Promotes Angiogenesis and Anastomosis which Is Critical for the Preservation of Vascular Integrity After Kidney Injury

Brooke M. Huuskes,[1] Alexander Ruvantha Pinto,[2] Chrishan S. Samuel,[3] Sharon D. Ricardo.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, Victoria, Australia; [2]Australian Regenerative Medicine Inst, Monash Univ, Clayton, Victoria, Australia; [3]Dept of Pharmacology, Monash Univ, Clayton, Victoria, Australia.*

Background: We previously reported that the combination of mesenchymal stem cells (MSCs) and serelaxin (Rln) attenuates ureteral obstruction (UUO)-induced fibrosis. However the affect on endothelial cell regeneration is yet to be elucidated. Here we tested the hypothesis that a mechanism of repair after fibrosis is induced via endothelial anastomosis and sprouting in the presence of MSCs and Rln.

Methods: Live cell imaging of human bladder endothelial cells (HBECs) and human umbilical vein endothelial cells (HUVECs) in tube forming assays were conducted with MSC-conditioned media and Rln (1-100mg/mL) to observe their affects on anastomosis. Spheroid assays determined the effects of MSC and Rln on HBECs and HUVECs sprouting *in vivo*. Proliferation of HBECs and HUVECs in the presence of MSCs and Rln was investigated. A qPCR for angiogenic genes was performed on MSCs cultured with or without Rln (100ng/mL). Endothelial integrity was visualized using CD31 protein localization in kidneys from mice 3, 5 and 7days post-UUO, with or without MSCs Rln (n=4-6/group).

Results: Anastomosis of HBECs was modulated in the presence of MSC-conditioned media and Rln with tube number and branch length increased compared to control. HUVECs readily formed sprouts in culture, which was enhanced when both Rln and MSCs were present. The migration capacity of MSCs towards injured HBECs was significantly increased when Rln was added. Rln induced the expression of angiogenic genes from the MSCs. Immunofluorescent microscopy of CD31 determined a decrease of endothelial integrity in a time-dependent manner *in vivo*. However the administration of MSCs and Rln preserved the vasculature.

Conclusions: These results suggest that both anastomosis and sprouting is enhanced only when both MSCs and Rln are used in combination. This may be in part due to Rln-induced release of angiogenic factors from MSCs which may aid in revascularization of the fibrotic kidney.

Effects of Adipose Derived Stem Cells in a Model of Chronic Renal Hypoxia

Crysthiane Saveriano Rubiao, Jose Tarcisio Giffoni, Rosemara Silva Ribeiro, Milene Subtil Ormanji, Vanessa A. Varela, Mirian A. Boim. *Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Chronic renal artery stenosis causing chronic hypoxia may lead to irreversible damage of the kidney with progressive deterioration of renal function. Due to reduced regenerative abilities of the kidney, mesenchymal stem cells (MSC) emerge as an alternative therapy. The aim of this study was to investigate the effects of MSC, isolated from adipose tissue (ASC) on renal fibrogenesis induced by chronic renal artery stenosis.

Methods: Left renal artery of male Wistar rats was partially occluded and ASC were injected through caudal vein. ASC were characterized by their immunophenotype/multipotentiality. To analyze the migration and retention time, labeled ASC were injected 6 weeks after renal occlusion (RO) and analyzed 24, 48, 72 hours or 15 days after injection by flow cytometry. Caudal systolic blood pressure (SBP) was weekly estimated. Renal function and the mRNA expression levels of collagen I (Col I), Fibronectin (FN) and TGF-β were determined by qPCR, 6 weeks after renal artery occlusion in the following groups: Sham; Stenotic control (StC, receiving PBS i.v.); Stenotic + ASC (S+ASC). ASC were injected 3 and 5 weeks after RO i.v.

Results: After 48 hours cells were retained in both kidneys, stenotic and contralateral followed by heart and lung. After 15 days the presence of ASC decreased significantly in the lungs and heart but they were still present in the kidneys. StC animals showed progressive increase in SBP while the S+ASC rats had a stabilization of SBP with no further increases after 5 weeks. Plasma creatinine was similar among groups however, StC animals developed proteinuria which was reduced by ASC treatment. There was an increase in the expression of ColI, FN and TGFβ in the stenotic kidney (cortex and medulla) which was reversed by ASC treatment.

Conclusions: In conclusion ASC prevented further increase in SBP and reduced the expression of molecules induced-fibrosis. ASC migration and retention in the clipped and contralateral kidneys can be potentially beneficial to restore damaged tissue and to preserve the function of the contralateral kidney.

Therapeutic Effects of Erythropoietin Producing Kidney Mesenchymal Stem Cell Derived Microparticles on Anemia in Chronic Kidney Disease Mice

Hoon Young Choi, Mirae Lee, Yuri Kang, Ah Ran Choi, Sung-Kyu Ha, Hyeong Cheon Park. *Dept of Internal Medicine, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Progression of chronic kidney disease (CKD) results in aggravation of erythropoietin (EPO)-dependent anemia. Microparticles (MPs) shed from kidney mesenchymal stem cells (KMSC) have been demonstrated to confer protective effects against acute kidney injury and kidney fibrosis via transfer of messenger RNA. Previous studies have demonstrated improvement of renal anemia by EPO transfected MSC. We investigated whether MPs derived from EPO producing KSMC can exert therapeutic effects on anemia in CKD mice.

Methods: Mouse model of CKD and renal anemia was induced by the electrocoagulation of right renal cortex and sequential left nephrectomy. Six weeks post-nephrectomy, CKD and anemia was confirmed via blood urea nitrogen (BUN) and hemoglobin measurements as well as renal histology. Stable human EPO-producing KMSC (EPO-KMSC) and their MPs isolated by differential ultracentrifugation were injected intraperitoneally into established CKD mice and followed for 2 weeks (EPO-KMSC: 1×10^6 per mice, MP: 2×10^7 per mice). BUN and hemoglobin were evaluated and degree of renal tubulointerstitial damage was examined for 2 weeks after CKD.

Results: EPO secretion from EPO-KMSC was confirmed to sustain over 4 weeks in vitro and RT PCR revieled the presence of EPO mRNA within MPs. Injected EPO KMSC-derived MPs were demonstrated within tubulointerstitial area. Animals that received EPO-KMSC and MPs demonstrated significantly lower BUN levels compared to CKD control mice (60±2, 62±7 vs.83±7 mg/dL, P<0.05, respectively). Importantly, hemoglobin levels were significantly higher in CKD mice treated with EPO-KMSC and MPs compared to CKD control mice (11.7±0.1, 11.3±0.5 vs.9.7±0.5 g/dL, P<0.05, respectively).

Conclusions: The use of EPO secreting MSC is a viable strategy for cell therapy in renal anemia. Our results suggest that EPO-KMSC derived MPs as well as EPO-KMSC can improve renal function and renal anemia in CKD mice.

Transplantation of Human Embryonic Mesenchymal Stem Alleviates Lupus Nephritis in MRL/lpr Mice

Yuan Li,[1] Yaping Fan,[2] Shi Hui,[3] Chen Xiao Lan.[4] *[1]Affiliated Hospital of Nantong Univ, Nantong, China; [2]Affiliated Hospital of Nantong Univ, Nantong, China; [3]Affiliated Hospital of Nantong Univ, Nantong, China; [4]Affiliated Hospital of Nantong Univ, Nantong, China; [5]Affiliated Hospital of Nantong Univ, Nantong, China.*

Background: Compared with bone marrow derived MSC, embryo-derived MSC have greater expansion and differentiation potentials. T helper cell 17(Th17) and interleukin 17(IL-17) is closely related to the occurrence and development of Lupus. The glial cell-derived neurotrophic factor (GDNF) which is closely related to the kidney development is found to be a kidney protection factor and can increase the renal protective effects of stem cells as well. Persephin (PSP) is a member of the family of GDNF and also involves in the kidney development. We investigated the effects of human embryonic MSC (hMSC) in lupus nephritis in MRL/lpr mice.

Methods: The MRL/lpr mice were divided into 2 groups: Control, hMSC group. hMSC were injected at one dose of 1×10^6/200ul twice (at the 16th, 19th weeks of age) through tail vein. Mice were sacrificed at 24th weeks of age.

Results: Multi-treatment of hMSC was able to increase the survival, decrease the levels of 24-h proteinuria, and anti-double-stranded DNA (dsDNA) antibody. hMSC treatment Alleviated the extent of renal injury such as crescent formation and Interstitial inflammatory cell infiltration in MRL/lpr mice. hMSC treatment also inhibited Th17 cell differentiation in spleen and decrease the serum level of IL-17. The level of GDNF and PSP was increased in renal of hMSC treatment MRL/lpr mice.

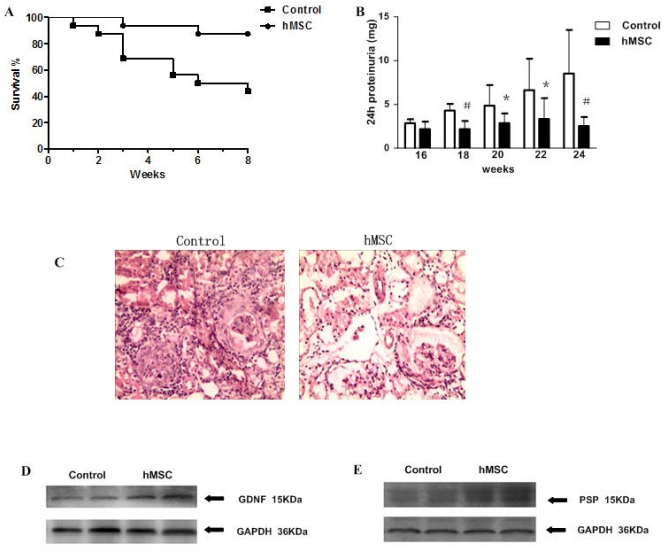

Figure1. hMSC transplantation alleviates lupus nephritis in MRL/lpr mice.(A). hMSC treatment prolongs survival(p<0.01 vs Control).(B) hMSC significantly reduced urine protein (*p<0.05 vs Control).(C) Representative hematoxylin and eosin staining of renal sections from each group. Original magnification, ×400.(D)(E)Western blot analyses showed that hMSC treatment MRL/lpr mice has increased expression of GDNF and PSP (*p<0.05 vs Control).

Conclusions: These findings indicated that hMSCs transplantation might be a potentially promising approach in the treatment of lupus nephritis, possibly by inhibiting Th17 cell differentiation and increasing GDNF and PSP level in renal.

Microarray Analysis of Gene Expression to Compare Low Serum Cultured Adipose Derived Stromal Cell with High Serum Yutaka Kamimura, Naotake Tsuboi, Takayuki Katsuno, Shoichi Maruyama. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan.*

Background: We established human adipose tissue-derived stromal cells (hASCs) cultured in low (2%) serum (hLASCs), which demonstrated great therapeutic potential for inflammatory diseases. We have already reported that hLASCs significantly attenuated rat folic acid-induced acute kidney injury than did hASCs cultured in high (20%) serum (hHASCs). However, the mechanism for hLASCs to exert greater anti-inflammatory function than hHASCs was partly evaluated. In the current study, we compared gene expression profiles and functional difference between hLASCs and hHASCs.

Methods: Human abdominal subcutaneous adipose tissue was obtained from patients underwent liposuction. Cells were cultured under the two conditions; a low serum culture medium containing 2% fetal bovine serum (FBS) and a high serum culture medium containing 20% FBS. Total RNA was isolated from hLASCs and hHASCs. We performed cDNA microarray analysis in total RNA from hLASCs and hHASCs and confirmed microarray data by real-time PCR. Moreover, we performed in vitro functional analysis in some identified molecules.

Results: 312 genes were significantly (False Dicovery Rate:FDR < 0.01) up-regulated (Fold Change > 5.0) and 211 genes were down-regulated in hLASCs. Microarray analysis revealed several differentially expressed genes including C-X-C chemokine receptor type 7 (CXCR7), superoxide dismutase (SOD) 3, Toll-like receptor (TLR) 3. Data were validated by real-time PCR, confirming the differential expression profiles of CXCR7 (Fold change 26.54), SOD3 (Fold change 4.79) and TLR3 (Fold Change 2.22) in hLASCs. Related to CXCR7 function, hLASCs demonstrated accelerated cell migration depending on SDF-1α, a CXCR4/7 agonist, compared to hHASCs. For TLR activation, hLASCs secreted more IL-6 and MCP-1 in response to poly:IC for TLR3 stimulation than hHASCs, but not to LPS for TLR4 ligand.

Conclusions: Our data suggest hLASCs can be characterized by cell migration, intense oxidative stress and immune response through toll-like receptor activation, which determine therapeutic potential of hASC.

FR-PO218

Renoprotective Effects of Tonsil-Derived Mesenchymal Stem Cells in Gentamicin-Induced Acute Kidney Injury (AKI) Duk-Hee Kang, Eun Sun Ryu, Hyun-soo Shin, Jiyeon Ko. *Ewha Womans Univ School of Medicine.*

Background: Gentamicin (GM)-induced AKI occurs in 10-20% of treated patients. GM is accumulated in renal epithelial cells, which causes the loss of the brush border, apoptosis and overt necrosis of renal tubules. Recent developments in stem cell research have shown a promise for the treat-ment of AKI, however the mechanisms underlying the improvement in kidney function provided by stem cell therapy remain unclear. Tonsil-derived mesenchymal stem cells(T-MSCs) can be isolated from tonsils of the patient undergoing tonsillectomy, andare reported to be effective in treatment of various diseases. The aim of this study is to investigate the therapeutic potential of T-MSCs in the treatment of AKI induced by GM.

Methods: Twenty male Sprague-Dawley rats were divided into four groups: Control, GM (140 mg/kg/day, ip for 10 days), GM+T-MSCs ($1x10^7$ cells, intravenous injection at 1 day after the 1st GM injection) and T-MSC group. To examine the intra-renal localization of T-MSCs, T-MSCs were labeled with PKH-26 red fluorescence before infusion. Measurement of BUN, Cr, proteinuria and histologic analysis including TUNEL staining were performed on 16 days of GM injection. Effect of T-MSC on renal tubular cells was also evaluated using a transwell co-culture system of NRK cells and T-MSC. Intracellular ROS was analyzed by measuring NOX activity, H_2O_2 generation, NOX mRNA expressions with DCF-DA staining.

Results: PKH-26-labeled T-MSCs were observed in renal tubular cells in GM+T-MSCs group. The infusion of T-MSCs preserved renal function with a decrease in proteinuria. T-MSCs also ameliorated renal tubular dilatation and reduced apoptosis of renal tubular cells in the rats with GM-induced AKI. The infusion of T-MSCs downregulated the expression of Bax, Cytochrome *c*, Cleaved caspase-9 and -3 and upregulated Bcl-2 of renal cortical tissue. In-vitro study revealed an amelioration of GM-induced oxidative stress and apoptosis of NRK cells by T-MSC.

Conclusions: Our results suggest that T-MSCs protect the kidney from GM-induced AKI, possibly via the mechanism of modulation of oxidative stress and apoptosis.

Funding: Government Support - Non-U.S.

FR-PO219

Exosomes Secreted by Human Urine-Derived Stem Cells Could Prevent Kidney Complications from Type I Diabetes in Rats Zhenzhen Jiang, Yumei Liu, Ying Fan, Jing Zhang, Yang Fei, Niansong Wang. *Dept of Nephrology and Rheumatology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.*

Background: Stem cells are currently the main candidates for the development of new treatments for diabetic nephropathy, as they may exert their therapeutic effects mainly through paracrine mechanisms. Exosomes derived from stem cells have been reported to play an important role in kidney injury.

Methods: Exosomes from conditioned medium of human urine-derived stem cells (USCs-Exo) were isolated using ultra-filtration and purification methods. USCs-Exo was then verified by morphology characteristics and specific biomarkers. After the establishment of the streptozotocin (STZ) induced Sprague - Dawley (SD) rats' model, the effects of USCs-Exo on kidney injury were observed via tail intravenous injection of USCs-Exo or control weekly until 12 weeks. In vitro, podocytes cultured in high glucose medium were treated with USCs-Exo to test the protective effect of USCs-Exo on podocytic apoptosis.

Results: USCs were cultured and were verified by positive markers of CD29, CD73, CD90 and CD44 antigens, and negative markers of CD34 and HLA-DR. USCs-Exo were 100 nm spherical vesicles under transmission electron microscopy and the specific markers including CD9, CD63 and CD81. Intravenous injections of USCs-Exo could potentially reduce the urine volume and urinary microalbumin excretion, prevent podocytes and tubular epithelial cells apoptosis, suppress the caspase-3 overexpression and increase glomerular endothelial cells proliferation in diabetic rats. In addition, USCs-Exo could reduce podocytic apoptosis induced by high glucose in vitro.

Conclusions: USCs-Exo may have the potential effect to prevent kidney injury from diabetes by inhibiting podocytes apoptosis and promoting vascular regeneration.

FR-PO220

Characterization of a Nanotube-Based Mechanism for Hematopoietic Stem Cell-Mediated Kidney Repair in Cystinosis Spencer M. Goodman,[1] Swati Naphade,[1] Jay Sharma,[1] Heloise P. Gaide Chevronnay,[2] Pierre J. Courtoy,[2] Stephanie Cherqui.[1] *[1]Dept of Pediatrics, Div of Genetics, Univ of California, San Deigo, La Jolla, CA; [2]Cell Biology Unit, de Duve Inst, Univ Catholique de Louvain, Brussels, Belgium.*

Background: Cystinosis is a lysosomal storage disorder caused by mutations in the *CTNS* gene, encoding the lysosomal transmembrane transporter cystinosin. As a consequence, cystine builds up in all tissues and eventually causes multi-organ degeneration. Patients develop renal Faconi syndrome before the age of one, and ultimately, end-stage renal failure. We previously showed in *Ctns*$^{-/-}$ mice that transplantation of hematopoietic stem cells (HSCs) resulted in abundant integration of bone marrow-derived cells into all tissues and long-term kidney preservation. To address the cellular mechanism of kidney rescue, we observed that HSCs differentiated into macrophages that extended intercellular bridges called tunneling nanotubes (TNTs). TNTs were seen transporting cystinosin-GFP lysosomes into diseased proximal tubular cells (PTCs) across the tubular basement membrane.

Methods: *In vitro* co-culture of primary DsRed Ctns$^{-/-}$ fibroblasts with IC21 macrophages expressing CTNS-GFP allowed visualization of bidirectional lysosome transfer. We designed an application using ImagePro to automatically quantify TNTs via morphological filters. *In vivo*, we further evidenced glomerular rescue by HSCs in DsRed Ctns$^{-/-}$ mice transplanted with GFP-expressing HSCs. Cells and glomeruli are currently analyzed by confocal and electron microscopy.

Results: We thus showed that HSC-derived cells result in morphological and functional preservation of both PTCs and glomeruli in grafted *Ctns*$^{-/-}$ mice. However, while PTC rescue implied differentiation of donor cells into F4/80+ macrophages, glomeruli-engrafted HSCs were apparently not macrophages. Work is ongoing to characterize the cellular mediators of glomeruli repair.

Conclusions: In conclusion, HSC transplantation can repair and preserve near-normal kidney architecture in cystinosis. Understanding mechanisms underlying kidney repair could spur the development of novel stem cell-based therapies for degenerative renal disorders.

FR-PO221

Towards the Clinical Application of Gene-Modified Hematopoietic Stem Cell Transplantation for Cystinosis Tatiana Vm Lobry, Jay Sharma, Sarah Ur, Celine Rocca, Betty Cabrera, Stephanie Cherqui. *Pediatrics, Univ of California San Diego, San Diego, CA.*

Background: Cystinosis is an autosomal metabolic disease caused by mutations in the *CTNS* gene, encoding a lysosomal cystine transporter, leading to cystine accumulation and multi-organ failure. Affected individuals present before 2 years of age with a Fanconi syndrome and eventually progress to end-stage renal failure. Treatment with cysteamine does not prevent these complications. We showed previously that wild-type HSC transplantation could treat cystinosis in the $Ctns^{-/-}$ mice. Thus, we developed an autologous transplantation strategy of HSCs genetically modified *ex vivo* to express a functional *CTNS* gene. Preclinical studies using a SIN-lentivirus vector containing *CTNS* to transduce $Ctns^{-/-}$ HSCs and transplanted in $Ctns^{-/-}$ mice led to cystine reduction in all tissues and kidney function improvement.

Methods: Pharmacological and toxicological studies are in progress. We established the optimal conditions to transduce human $CD34^+$ HSCs with our lentiviral vector to obtain a Vector Copy Number (VCN) included between 1 and 3. We performed Colony Forming Unit (CFU) assays to ensure normal proliferation and differentiation of transduced human $CD34^+$ HSCs from healthy donors and cystinotic patients and the In Vitro Immortalization (IVIM) assay, a genotoxicity test. Serial transplantations in the $Ctns^{-/-}$ mice will assess the safety of our vector *in vivo*.

Results: While we obtained VCN within the range for healthy donors $CD34^+$ HSCs, the VCN for the $CTNS^{-/-}$ $CD34^+$ HSCs is below 1, requiring further optimization. CFU assays did not show aberrant differentiation of the transduced $CD34^+$ cells from the healthy donors and cystinotic patients. Finally, no immortalized clones were observed with the IVIM assays suggesting a good safety profile of our vector. These results will be included in our IND for a phase 1 clinical trial for cystinosis. The *in vivo* serial transplantations are in progress.

Conclusions: This work represents the first stem cell and gene therapy treatment strategy for cystinosis and should lead to a phase I clinical trial.

Mesenchymal Precursor Cell Therapy for Diabetic Nephropathy: 24 Week Results from a Phase 2A Randomized Controlled Trial David K. Packham,[1] Ian R. Fraser,[2] Peter G. Kerr,[3] Silviu Itescu,[4] Karen R. Segal.[4] *[1]MRRG, Melbourne, VIC, Australia; [2]Epworth H, Melbourne, VIC, Australia; [3]Dept Neph, Monash M C, Melbourne, VIC, Australia; [4]Mesoblast PLC, NY, NY.*

Background: Renal inflammation and endothelial dysfunction contribute to the etiology of diabetic nephropathy (DN). Bone marrow derived mesenchymal precursor cells (MPC) can modulate both inflammatory cells and microvasculature. We conducted a randomized, placebo (PBO) controlled, dose-escalating trial of allogeneic MPC in 30 subjects with type 2 DN.

Methods: Patients (24 men, 6 women) with an estimated glomerular filtration rate (eGFR) of 20-50 ml/min/1.73/m2 and on a stable regimen of renin-angiotensin inhibition were randomized to a single IV infusion of PBO (saline) or 150 million (M) or 300M MPCs (N=10 per group). Patients have been followed-up for 24 w. Baseline mean age was 70 years mean eGFR was 34.6, 35.7 and 34.6 ml/min/1.73/m2 for PBO, 150M and 300M, and 19/30 patients had eGFR>30.

Results: There were no treatment-related adverse events. For eGFR change from baseline at 24 w, the least square mean (LSM) differences from PBO were 3.2+2.5 (8.1%) in both 150M and 300M groups. PBO-adjusted treatment differences were greater in pooled MPC with baseline eGFR>30: 4.9+2.3 (+12%) at 24w. The LSM differences from PBO for mean individual annualized slopes of eGFR change over 24w was 6.8+4.8 in both treatment groups. Baseline IL6 levels correlated with SCr and eGFR improvement at 12 w in the MPC groups ($r=0.57$ and 0.50; both $p<0.05$) but not in PBO. The LSM differences from PBO for mean individual annualized slopes of eGFR change over 24w was 7.8+4.8 ml/min/1.73 m2/y in pooled MPC patients with baseline IL-6 >3.5 pg/dl and 5.6+5.0 in MPC patients with baseline IL-6 <3.5 pg/dl, suggesting greater preservation or improvement in eGFR relative to PBO in the presence of elevated IL-6.

Conclusions: In this first in humans study, a single MPC infusion improved or stabilized GFR over 24w. Baseline eGFR>30 and high IL-6 levels suggest two biomarkers that may predict efficacy with MPC treatment. Positive response to MPC therapy may be enhanced by the presence of non-fibrotic, but at-risk, renal tissue and aberrant pro-inflammatory milieu.

Long-Term Effect of Methylprednisolone Pulse and Autologous SVF (Stromal Vascular Fraction) Therapy in Severe IgA Nephropathy with CKD Stage III Byoung-Soo Cho,[1] Yumi Choi,[2] Jin-Soon Suh.[3] *[1]TheAll Medical Hub Kidney Center, MIRAE ING Research Inst, Seoul, Republic of Korea; [2]Dept of Pediatrics, Gwangmyeong Sung-Ae Hospital, Gwangmyeong-si, Gyeonggi-do, Republic of Korea; [3]Dept of Pediatrics, College of Medicine, The Catholic Univ of Korea, Bucheon-si, Gyeonggi-do, Republic of Korea.*

Background: Up to date there is no specific method of treatment in severe IgA nephropathy with CKD, but giving ACE inhibitor, angiotensin II receptor blocker(ARB), omega-3 etc. and eventually almost all cases fall into CKD V and need KTP or dialysis. Cell-based therapy is an emerging field in nephrology field especially adipose derived stem cells(ASCs). The beneficial effects of mesenchymal stem cell occur through differentiation-independent pathways include increased cell survival and proliferaton, decreased inflammation, immune modulation, tissue regeneration etc.

Methods: We tried methylprednisolone(MP) pulse therapy followed by autologous SVF(stromal vascular fraction), which contained ASCs in severe IgA nephropathy with CKD stage III. This case was 44years old female patient, Renal biopsy finding showed Grade IV(Lee's classification) with CKD stage 3. MP pulse was tried 6 cycles followed by autologous SVF were injected through intravenously 4 times at 3 weeks interval.

Results: Initial renal biopsy findings before treatment(Tx) showed 61% scerotic glomeruli, however follow up renal biopsy 18 months after Tx showed 41% sclerotic glomeruli and disappeared immune deposits, The serum creatinine level before Tx was 1.77mg/dl with GFR 35ml/min, however 18 months after Tx serum creatinine was 1.03mg/dl with GFR 61ml/min.

Conclusions: In conclusion MP pulse therapy with autologous SVF treatment in intractable IgA nephropathy might be a promising therapeutic means without any notable side-effect or complications especially in early stage CKD, although the efficacy and safety, of SVF infusion therapy needs long term studies.

Extracellular Vesicles in Glomerular VEGF Homeostasis Sargis Sedrakyan,[1] Stefano Porta,[2] Hasmik Soloyan,[1] Nikita Tripuraneni,[1] Roger E. De Filippo,[1] Benedetta Bussolati,[2] Laura Perin.[1] *[1]Children's Hospital Los Angeles; [2]Univ of Turin.*

Background: Strict regulation of VEGF signaling between podocytes and glomerular endothelial cells (GEC) is critical for GEC survival and function, therefore, loss of glomerular VEGF homeostasis during disease progression can impact GEC integrity leading to decline in glomerular function. Importantly, recent studies have described extracellular vesicles (EVs) to play important role in stem cell mediated paracrine modulation, including in kidney. We have already established that amniotic fluid stem cells (AFSC) are renoprotective, and we hypothesize that EVs released within damaged glomeruli are involved in VEGF regulation. Herein, we investigate the impact of AFSC derived EVs in the maintenance of glomerular VEGF homeostasis.

Methods: Using qPCR and ELISA we measured VEGF expression along the course of disease progression in isolated glomeruli of mice affected by Alport Syndrome (AS). Endothelium morphology was evaluated by IHC and TEM. GEC were FACS sorted from a GEC specific Tek reporter mice and studied by gene and protein arrays for VEGF/VEGF-R, oxidative stress, and apoptotic pathways. Co-cultured GEC and AFSC overstimulated with VEGF were used to study the direct role of EVs in VEGF regulation. EVs were characterized and injected into AS mice for *in vivo* evaluation.

Results: Mice at advanced stages of Alport disease presented with aberrant VEGF activity within glomeruli, significant GEC apoptosis, oxidative stress and loss of GEC fenestrations. Delivery of AFSC derived EVs normalized VEGF expression and ameliorated endothelial damage. Importantly, the soluble receptor of VEGF, sFlt1—involved in regulating VEGF signaling—was also modulated upon treatment, indicating a VEGF/sFlt1 mechanism of regulation by EVs. In vitro experiments further confirmed the direct role of EVs in VEGF/sFlt1 regulatory mechanism.

Conclusions: In conclusion, our data demonstrate for the first time the aberration of VEGF signaling within AS glomeruli. We further showed that AFSC derived EVs play an important role in maintaining glomerular homeostasis of VEGF signaling, so critical to normal GEC integrity and function, presenting with a potential for new targeted therapies in CKD.

FR-PO225

Renal Exosomes Store and Transfer the Ischemia Preconditioning State and Protect Rats with Severe Renal Ischemia Katherine J. Kelly,[1] Jesus H. Dominguez.[1,2] *[1]Medicine, Indiana Univ Medical School, Indianapolis, IN; [2]Medicine, Veterans Administration, Indianapolis, IN.*

Background: Acute Kidney Injury (AKI) is a risk factor for chronic kidney disease (CKD) and end-stage renal disease (ESRD). We have reported that intravenous renal cell transplants (IRCT) improve outcomes in rats with AKI (AJP 303:F357, 2012). IRCT action was mediated by relatively small number of anchored and retained cells, and we hypothesized that cells amplified renal protection by releasing exosomes (EX) acting at a distance.

Methods: We tested if renal EX from cultured cells used for IRCT improved AKI. Normal Sprague Dawley rats (SD, n = 4-7) were subjected to 45 minutes of bilateral ischemia (IR). Renal exosomes (600 ug/protein/rat) were then given intravenously .

Results: There were 5 groups of rats: 1, sham, no IR; 2, renal ischemia (IR) untreated (NO-EX); IR treated with heat inactivated EX (HI-EX); 3, IR treated with normal EX (NL-EX), RI treated with EX released by kidney cells subjected to ischemia preconditioning (IPC-EX). In sham, serum creatinine was 0.3±0.03 at 24 hrs and 0.3±0.02 at 48 post-surgery. In NO-EX it was 2.1±0.6 and 1.7, post IR, respectively. In HI it was 2.2±0.1 and 1.6±0.3. However, in NL-EX it was 2.4±0.4 and 0.78±0.1. The most striking effect was from IPC-EX: 2.0±0.2, and 0.54±0.1, p <0.05 vs. all including NL-EX. Kidney weight (mg/gm body weight) 6 days post IR was also improved by EX: 3.8±0.1 in sham; 6.7±0.6 in NO-EX; 6.7±0.6 in HI; 5.2±0.2 in NL-EX 5.2±0.2, and 4.4±0.2 in IPC-EX, which was significantly lower than all IR groups, including NL-EX. Neutrophils (PMN) in IPC-EX were also reduced by 65 % ($p<0.05$) when compared to NL-EX. IPC-EX reduced renal C3 expression in glomeruli and tubules by 73 % and 82 % respectively ($p < 0.05$ for both). IPC-EX also protected 76 % of renal tubules when compared to NO-EX.

Conclusions: IPC is effective but impractical. However, EX given IV can communicate the IPC state, reach the kidneys, modulate inflammation and protect function and structure following severe IR.

The Impact of Preexisting Chronic Kidney Disease on the Severity and Recovery of Acute Kidney Injury

Sung Yoon Lim,[1] Young Ju Na,[1] Myung-gyu Kim,[1] So-young Lee,[2] Sang-Kyung Jo,[1] Won-Yong Cho.[1] *[1]Dept of Nephrology, Korea Univ Hospital, Seoul, Korea; [2]Dept of Nephrology, Eulji Univ Hospital.*

Background: Recent observational studies have shown that a substantial proportion of patients with acute kidney injury (AKI) have often progression to chronic kidney disease (CKD). Among several risk factors for the development of CKD after AKI, decreased baseline glomerular filtration rate (GFR) represents an important risk factor. However, precise mechanisms involved in the development of fibrosis after AKI with preexisting CKD have not been completely ascertained. Here in this study, we assessed the impact of preexisting CKD on the severity and recovery of AKI in mouse model of 5/6 nephrectomy.

Methods: Male CD-1 mice underwent 5/6 nephrectomy or sham operation, and 6 weeks later ischemia reperfusion injury (IRI) was performed. On day 1, 7 and 28 after IRI, functional, histological, and molecular parameters were compared between them.

Results: Twenty five minutes clamping of renal pedicle in 5/6 nephrectomized mice did not provoke more severe functional, histological deterioration compared to normal mice on day 1 and 7. Similar elevations in SCr were observed in both groups until day 7 after IRI; however, SCr remained higher on day 28 in 5/6 nephrectomized mice compared to normal mice, suggesting that preexisting CKD does not modify severity of AKI but adversely affect the recovery process. From day 7 to 28, mRNA expression of p21, and protein level of pH3, both representing cell cycle arrest were significantly increased in 5/6 nephrectomized mice (CKD+AKI) compared to sham (sham+AKI). Treatment with p53 inhibitor after IRI resulted in not only decreased p21 and pH3 protein level, but also fibrosis in CKD+AKI mice, suggesting that epithelial cell cycle arrest is partially responsible for impaired recovery from AKI in 5/6 nephrectomized mice.

Conclusions: Taken together, reduced nephron mass do not seem to increase severity of AKI, but have negative effect on repair process, leading to development of fibrosis.

FR-PO227

Impaired Functional Recovery from Acute Kidney Injury in Rats with Preexisting Chronic Kidney Disease Predicts the Severity of De Novo Hypertension

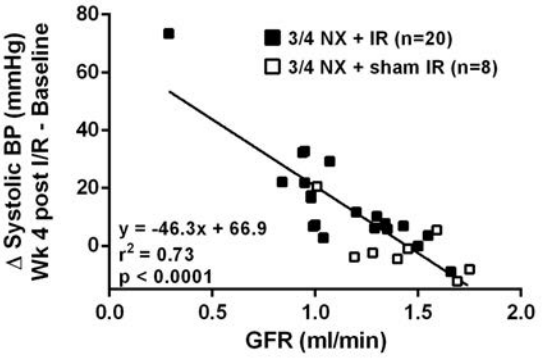
Aaron J. Polichnowski,[1,2] Karen A. Griffin,[1,2] Mana Dissadee,[1,2] Anil K. Bidani.[1,2] *[1]Edward Hines Jr. VA Hospital, Hines, IL; [2]Medicine, Loyola Univ Medical Center, Maywood, IL.*

Background: The mechanisms by which AKI accelerates the progression of CKD remain poorly understood. We have recently demonstrated that preexisting CKD predisposes to impaired recovery from AKI as evidenced by exaggerated levels of tubulointerstitial fibrosis and modest elevations in blood pressure at 4 weeks post injury. However, a rigorous examination of the relationship between impaired functional recovery from AKI and the development of hypertension has not been examined.

Methods: Male SD rats underwent normotensive 3/4 nephrectomy (3/4 NX) and were chronically instrumented with a BP radiotelemeter. Two weeks later, rats were subjected to 40 min IR (n=20) or sham IR (n=8). BP was assessed every 10 min, 24 hr/day for 4 weeks and glomerular filtration rate (GFR) was then assessed in the conscious state (FITC-inulin).

Results: As compared to baseline values, systolic BP was significantly elevated ($P<0.05$) in rats at 4 weeks post IR (134±2 vs. 149±5 mmHg, respectively) but not sham IR (139±4 vs. 140±2 mmHg, respectively). GFR was significantly less ($P<0.05$) in rats subjected to IR vs. sham IR (1.1±.1 vs. 1.4±.1 ml/min, respectively). As shown in Figure 1, a very strong negative correlation was observed between GFR and the increase in systolic BP over the 4 week protocol. S_{Cr} values 48 hours post AKI did not correlate with either GFR or the change in systolic BP at 4 weeks post AKI, indicating that the development of hypertension following IR was due to impaired recovery from AKI as opposed to a greater severity of AKI.

Figure 1



Conclusions: The development of hypertension following AKI in the presence of pre-existing CKD is likely to significantly contribute to the subsequent progression of CKD.

Exocytosis of Endothelial Lysosome-Related Organelles Hair-Triggers a Patchy Loss of Glycocalyx at the Onset of Sepsis

Joseph A. Zullo,[1] Jie Fan,[2] Tala F. Azar,[1] Wan-yi Yen,[2] Min Zeng,[2] Jun Chen,[1] Brian B. Ratliff,[1] Jungol Song,[3] John Tarbell,[2] Bingmei M. Fu,[2] Michael S. Goligorsky.[1] *[1]New York Medical College; [2]The City College of The City Univ of New York; [3]Ulsan Medical College, Seoul, Republic of Korea.*

Background: Endothelial surface glycocalyx (ESG) is a well-known regulator of leukocyte surveillance, vascular permeability, and a sensor of shear stress. ESG is degraded during sepsis, thus contributing to systemic multiorgan involvement. Our previous demonstration of a very early post-stress exocytosis of lysosome-related organelles (LRO) with their lytic enzymes led us to hypothesize that exocytosis of LRO may catapult a synchronized degradation of ESG.

Methods: To test this hypothesis we first analyzed the time-course of exocytosis of Weibel-Palade bodies and secretory lysosomes after application of lipopolysaccharides (LPS) to endothelial cells.

Results: Time-lapse video microscopy revealed that LROs undergo agitation and vectorial movement with a time course of a few minutes after LPS. In addition, spectrophotometry measurements illustrated an increase of lysosomal cargo, cathepsin B, within the media after 10min of LPS exposure. Two therapeutic maneuvers, a nitric oxide intermediate, NG-hydroxy-L-arginine (NOHA), and culture media conditioned by endothelial progenitor cells (EPC-CM) reduced the directionality and motility of LRO. The patchy loss of ESG occurring with the similar fast kinetics was confirmed using confocal fluorescence microscopy and Stochastic Optical Reconstruction Microscopy. The loss of ESG was blunted by pretreatment with NOHA or EPC-CM. Moreover, these treatments resulted in a significant reduction of mortality of septic mice.

Conclusions: In summary, above studies provide the first demonstration of the very early patchy disintegration of ESG which can be prevented by pretreatment with NOHA and EPC-CM, maneuvers that reduced exocytosis of LRO. Data support the hypothesis assigning to stress-induced exocytosis of these organelles the role of a hair-trigger for local degradation of ESG that in turn initiates leukocyte infiltration, increase in vascular permeability, and partially accounts for the later morbidity and mortality.

FR-PO229

Vitamin D Deficiency Contributes to Vascular Damage in Sustained Ischemic Acute Kidney Injury

Ana C. de Bragança,[1] Rildo A. Volpini,[1] Purvi Mehrotra,[2] Carlie M. Ivancic,[2] Lucia Andrade,[1] David P. Basile.[2] *[1]Nephrology, Univ of Sao Paulo School of Medicine, Sao Paulo, SP, Brazil; [2]Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN.*

Background: It has been shown that injury to the renal vasculature may play an important role in the pathogenesis of ischemic acute kidney injury (AKI). Reductions in microvasculature density may play a critical part in the progression of chronic kidney disease (CKD) following AKI-induced ischemia/reperfusion injury (IRI). Vitamin D deficiency (VDD) is associated to tubulointerstitial damage and fibrosis progression following IRI-AKI. We evaluated the effect of VDD in sustained IRI-AKI, hypothesizing that VDD contributes to vascular damage.

Methods: Wistar rats were fed 25(OH)D-free or standard diets for 35 days. On day 28, rats were randomized into four groups: control (sham), VDD, bilateral IRI and VDD IRI. Rats were analyzed 7 days after the surgeries.

Results: VDD rats showed impaired capillary density (by cablin staining) and reduced VEGF expression, even in the absence of injury. In addition, VDD IRI rats manifested a remarkable capillary rarefaction and also had increased RW/BW, tissue injury scores, FSP-1,

α-SMA when compared to either VDD or IRI rats. VDD IRI also had increased levels of infiltrating activated CD4+ and CD8+ cells secreting higher levels IFN-γ and IL-17 while the number of regulatory T cells was reduced, relative to IRI rats.

	Control n=6	VDD n=5	IRI n=7	VDD IRI n=7
RW/BW ratio	0.34±0.009	0.33±0.005	0.50±0.031[a,d]	0.58±0.030[a,d,i]
Vessel density %	100.0±14.08	77.45±3.33	75.50±6.91	53.42±8.58[b]
FSP1 +cells/field	5.99±1.28	7.35±0.79	18.31±1.72[b,e]	27.0±3.11[a,d,i]
α-SMA %	0.15±0.04	0.16±0.01	2.89±0.43	7.74±1.56[b,d,h]
VEGF %	30.56±3.05	20.51±5.49	16.56±2.08	13.42±4.49[c]

[a]p<0.001, [b]p<0.01 and [c]p<0.05 vs Control; [d]p<0.001 and [e]p<0.01 vs VDD; [h]p<0.01 and [i]p<0.05 vs IRI

Conclusions: VDD impairs renal capillary density and exacerbates fibrotic damage and pro-inflammatory milieu following AKI, which may contribute to the transition of CKD following AKI. *Funding: CAPES/CNPq/FAPESP, NIH DK63114 (DPB).*

FR-PO230

Exosome-Mediated Delivery of Pro-Survival MicroRNA-486-5p in Acute Kidney Injury Jose L. Vinas, Dylan Burger, Alex Gutsol, William A. Knoll, David Allan, Kevin D. Burns. *Nephrology, Dept of Medicine, Ottawa Hospital Research Inst, Univ of Ottawa, Ottawa, ON, Canada.*

Background: We recently showed that administration of human endothelial colony forming cells (ECFCs) and their exosomes to mice with ischemic acute kidney injury (AKI) attenuated renal damage. Our data also indicate that ECFCs release exosomes that are highly enriched in micro-RNA (miR)-486-5p and protect against hypoxia-induced endothelial cell apoptosis. MiR-486-5p targets phosphatase and tensin homologue (PTEN), which may enhance the pro-survival Akt pathway. In this study, we further examined the role of exosomes and miR-486-5p on the Akt pathway in vivo, and tested the hypothesis that exosomes transfer miR-486-5p to endothelial cells in vitro.

Methods: Mice with ischemic AKI were injected (i.v.) with exosomes at reperfusion. Kidneys were subjected to immunoblots and RT-PCR for miR-486-5p. Transfer of ECFC exosomes and miR-486-5p was studied in human umbilical vein endothelial cells (HUVECs).

Results: Bioinformatic analysis of the 10 most abundant miRs in ECFC exosomes revealed that they were all involved in the Akt pro-survival pathway. Inmice with AKI, exosome treatment significantly increased renal miR-486-5p levels (P<0.01 vs ischemia alone, n=6-7), associated with decreased PTEN expression, and increased Akt phosphorylation. In cultured HUVECs, ECFC exosomes labeled with the fluorescent dye PKH-26 localized to the perinuclear compartment. Treatment of HUVECs with ECFC-derived exosomes or co-culture of ECFCs with HUVECs caused a 40-fold increase in levels of miR-486-5p. Transfection of ECFCs with pre-miR-486-5p, followed by co-culture with HUVECs was associated with a further marked increase (~20-fold) in miR-486-5p levels in HUVECs (P<0.001 vs control, n=3). This effect was blocked by pre-incubation of HUVECs with ethylisopropyl amiloride (an inhibitor of exosome uptake).

Conclusions: These data suggest ECFC-derived exosomes exert renoprotective effects in AKI, possibly via the transfer of miR-486-5p to endothelial cells. Exosome-mediated transfer of miRs could represent a strategy to target pro-survival pathways in the injured kidney.

FR-PO231

The Role of Vascular Endothelial Cells in the Protective Effect of Delayed Ischemic Preconditioning in Renal Ischemia/Reperfusion Injury Xialian Xu, Xiaoyan Jiao, Nana Song, Xiaoqiang Ding. *Div of Nephrology, Zhongshan Hospital, Shanghai, China.*

Background: We have previously reported that up-regulation of miR-21 contributed to the protective effect of delayed ischemia preconditioning (IPC) in renal ischemia/reperfusion injury (IRI). The role of vascular endothelial cells in renal IRI is not well-understood. In the present study, we examined the role of vascular endothelial cells in the protective effect of miR-21 in renal delayed IPC.

Methods: For the delayed IPC and IR model, 4 d after IPC (15min ischemia) or sham surgeries, preconditioned mice were subjected to 35 min occlusion of bilateral renal pedicles, followed by 24 h reperfusion. Human umbilical vein endothelial cells (HUVEC) were treated with cobalt chloride for hypoxia model *in vitro*. Locked nucleic acid (LNA) modified anti-miR-21 or anti-scrambled was transfected into cells or delivered into the mice via tail vein injection less than 1 hour prior to IPC. Vascular permeability was determined by the Evans Blue dye. Cell apoptosis was estimated by Annexin V-FITC apoptosis detection. Expression of programmed cell death 4 (PDCD4) protein and miR-21 was examined by western blot and real-time PCR, respectively.

Results: Compared with the Sham+IR group, mice in the IPC+IR group showed significant improvement of renal function and histology injury (P<0.01). MiR-21 was up-regulated in the IPC+IR group with concomitant decline of PDCD4 (P<0.05) and improvement of vascular permeability (P<0.05). *In vitro*, miR-21 in HUVEC was increased in hypoxia, while PDCD4 expression was decreased. Knockdown of miR-21 by LNA anti-miR-21 attenuated the protection conferred by delayed IPC, with concomitant up-regulation of PDCD4 (P<0.05) and exacerbated renal vascular permeability (P<0.05). Cell apoptosis significantly decreased after knockdown of miR-21 *in vitro*.

Conclusions: Up-regulation of miR-21 in renal delayed IPC improved the apoptosis of vascular endothelial cell by inhibiting its target PDCD4. This may be another mechanism underlying the protective effect of the delayed IPC.

FR-PO232

Role of Vascular Mineralocorticoid Receptor in Renal Ischemia/Reperfusion Jonatan Barrera-Chimal,[1] Alan Le Mercier,[1] Sonia Prince,[1] Soumaya El Moghrabi,[1] Norma Bobadilla,[2] Frederic Jaisser.[1] *[1]INSERM U1138, Centre de Recherche des Cordeliers, Paris, France; [2]Inst de Investigaciones Biomédicas UNAM and INNSZ, Mexico City, Mexico.*

Background: Renal ischemia/reperfusion (IR) is a major cause of acute kidney injury and is associated with chronic kidney disease (CKD) development. Mineralocorticoid receptor (MR) antagonism prevents the acute and chronic consequences of renal IR. Whether the benefit of the MR antagonists is due to the blockade of the MR in the vessels is unclear.

Therefore we want to study the specific contribution of endothelial and smooth muscle cells (SMC) MR in acute and chronic consequences of renal IR.

Methods: To inactivate MR in endothelial cells (MR^{endoKO} mice), floxed MR mice ($MR^{fl/fl}$) were crossed with mice expressing the inducible Cre recombinase under the VEcadh promoter. To allow inactivate MR in smooth muscle cells (MR^{SMCKO} mice), $MR^{fl/fl}$ mice were crossed with mice expressing the inducible Cre recombinase under the SMA promoter. Sham surgery or bilateral renal IR for 20 min was performed in $MR^{fl/fl}$ and KO mice and the animals were studied at short term (24 h) and long term (30 days) after reperfusion.

Results: In $MR^{fl/fl}$ mice, IR induced renal dysfunction (plasma creatinine from 8.9±0.3 in sham to 33.8±4.8 umol/L in IR), tubular injury and increased mRNA levels of kim-1 (400-fold) and NGAL (220-fold). The MR^{endoKO} mice displayed similar alterations induced by IR as $MR^{fl/fl}$ mice. In contrast, after 24 h of IR, the MR^{SMCKO} mice presented normal renal function (plasma creatinine was 9.6±0.7 and 14.0±1.9 umol/L in sham and IR, respectively), absence of histological alterations and reduced kim-1 and NGAL levels.

After 30 days, the $MR^{fl/fl}$ mice developed CKD characterized by renal dysfunction (plasma creatinine from 10.5±0.1 in sham to 15±0.8 umol/L in IR), tubule-interstitial fibrosis and increased mRNA levels of fibronectin and Galectin-3 (2-fold). The MR^{SMCKO} mice developed similar alterations.

Conclusions: We provide evidence that the deficiency of MR in the SMC protects against the development of acute kidney lesions induced by IR, however MR deficiency in SMC did not impact the appearance of CKD induced by IR, suggesting that MR in other cell types is involved.

Renal Vein Hydrodynamic Fluid Delivery Ameliorates Established Renal Injury following Ischemia/Reperfusion Injury Jason Andrieu Collett,[1] Purvi Mehrotra,[1] David P. Basile,[1] Robert L. Bacallao.[2,3] *[1]Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN; [2]Div of Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; [3]Richard L. Roudebush VA Medical Center, Indianapolis, IN.*

Background: Past and current treatment for Acute Kidney Injury (AKI) is mainly supportive in nature; no therapeutic modalities to date have shown efficacy in treating the condition. While numerous experimental approaches can prevent AKI, there are few potentially translatable studies which may influence the course of established AKI. The goal of this study was to target vascular congestion and inflammation, which contribute to impaired renal perfusion and renal damage, following the established injury. We hypothesized that high-pressure retrograde hydrodynamic delivery (HD) of saline will improve established AKI, in part, by improving vascular congestion.

Methods: Male Sprague Dawley rats underwent left unilateral ischemia (35 min) and right unilateral nephrectomy or bilateral IRI (35min) and reperfusion for 24 hours to induce AKI. 0.5ml of isotonic saline was then injected into either the vena cava (VC) or retrograde to left kidney via the renal vein (RV) under high pressure (~60mmHg). Recovery was evaluated via serum creatinine and accumulation of immune cells were evaluated using FACS.

Results: Average serum creatinine at 24hrs was similar between groups (sCre=3.3mg/dl), however, RV-HD treated rats showed a rapid improvement in serum creatinine over the following 24 hours vs VC HD rats (24 to 48 hr Δ serum creatinine -0.544 mg/dl vs. +0.6375 mg/dl; p=0.0237). To evaluate effects on inflammation, bilateral IRI rats subjected to left-RV HD resulted in a significant reduction in CD4+ (54%±18; p<0.05), CD8+(60%±8; p<0.05), B cells (56%±3.5; p<0.05) and DC/Macs (71%±13; p<0.05) compared with VC rats.

Conclusions: These results indicate that high pressure retrograde HD may provide a novel and effective therapeutic strategy for the treatment of AKI and transition of AKI to CKD.

FR-PO234

Human Adipose Stromal Cells Ameliorate Renal Injury and Attenuate Capillary Rarefaction following Ischemia-Reperfusion Jason Andrieu Collett, Purvi Mehrotra, Dmitry O. Traktuev, Stephanie Merfeld-Clauss, Keith March, David P. Basile. *Indiana Univ School of Medicine, Indianapolis, IN.*

Background: Acute kidney injury (AKI) is a syndrome characterized by the rapid loss of the kidney's excretory function, resulting in excess of 17 million hospital admissions a year. Although the tubular epithelium is the primary target of ischemic injury, early damage to endothelial cells contribute to AKI by resulting in impaired perfusion. Moreover, renal capillary density is permanently compromised in rats following AKI induced by ischemia reperfusion (IRI), which is hypothesized to promote CKD. Therefore, strategies to preserve capillaries may impact both short-term recovery and long-term function post-AKI. Adipose stromal cells (ASCs) have pro-angiogenic and anti-inflammatory properties. It is hypothesized that ASCs facilitate repair by capillary preservation, revascularization of damaged endothelium and decreased inflammation.

Methods: Male Sprague Dawley rats were subject to bilateral IRI (40 min). At the time of reperfusion, ~$2x10^6$ human ASCs (hASCs; n=15) or vehicle (n=14) were injected into the suprarenal abdominal aorta. Recovery was evaluated via serum creatinine and capillary specific staining. Accumulation of immune cells in the kidney were evaluated using FACS.

Results: hASC-treated rats had a 90% survival by day 7, compared with 70% for vehicle. Serum creatinine showed a significant reduction in hASC-treated rats vs vehicle at 48 hrs, (35%; p=0.0008). By day seven, vehicle-treated rats showed a reduction in renal capillary density relative to sham (43%), which was significantly attenuated in hASC-treated rats (28%). Additionally, hASCs-treated rats exhibited a significant decrease in CD4+ (62%±16.8) and CD8+ (72%±3.5) T-cell infiltration ($p<0.05$). Further, IL-17 cytokine secreted by CD4+T cells was also reduced by ~40% in hASC-treated rats (185±66) as compared to vehicle (299±83.9). Conversely, the number of regulatory T cells was increased in hASC-treated rats compared with vehicle (35%; $p<0.05$).

Conclusions: These results suggest that ASCs may ameliorate injury, at least in part, by preserving capillary density, decreasing inflammation and restoring renal function.

Studying the Effect of Induced Expandable Human Kidney Progenitor Cells on Renal Function Using Transcutaneous Assessment Zeneida Herrera Perez,[1] Oren Pleniceanu,[2] Dorit Omer,[2] Benjamin Dekel,[2] Norbert Gretz.[1] *[1]Medical Research Center, Medical Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany; [2]Sheba Center for Regenerative Medicine, Sheba Medical Center, Tel Aviv, Israel.*

Background: The use of induced stem cells from adult tissues is a promising therapeutic approach for the treatment of kidney diseases. However, traditional techniques to monitor recovery from damage or a delay in chronic renal disease development after cell therapy are cumbersome and time-consuming, as well as inaccurate to detect early changes in function. A recent method allows the evaluation of renal function transcutaneously, using an optical device and the exogenous renal marker FITC-sinistrin, with no need for plasma or urine samples. For the first time, we have studied the effect of human adult kidney epithelial cells (hKEpCs) induced to stably overexpress the SIX2 or OSR1&SIX2 genes in a cisplatin (CP)-induced injury model using the transcutaneous assessment of renal function.

Methods: Three different animal groups were established: induced SIX2-hKEpCs, SIX2&OSR1&mCherry-hKEpCs and CP control group. On days 2 and 7 following a single dose of CP (7mg/kg b.w.), rats received intravenously either vehicle or $1x10^6$ of the corresponding cell type. Kidney function was assessed over 14 days transcutaneously. In addition, urinary and plasma parameters, as well as histological changes were evaluated.

Results: Before cell treatment, all the groups experienced a comparable decrease in renal function with respect to baseline. Transcutaneous measurement showed that both cell types improve renal function compared to control group, with a substantial amelioration on day 7 after CP administration. The rise of creatinine and urea serum levels was also ameliorated in the cell treated groups and the histological analysis supported the beneficial of hKEpCs administration shown in renal function.

Conclusions: SIX2- and SIX2&OSR1mCherry-hKEpCs display therapeutic potential in CP-induced injury, preventing loss of kidney function and diminishing renal tissue damage. The transcutaneous assessment of renal function is a suitable method to detect changes due to disease progression or therapeutic interventions.

Indole Analogs Have Novel Therapeutic Effects on Mitochondrial Diseases and Kidney Injury Takehiro Suzuki,[1] Tetsuro Matsuhashi,[1] Akihiro Matsuo,[1] Yuki Oba,[1] Koichi Kikuchi,[1] Hisato Shima,[1] Eikan Mishima,[1] Yasutoshi Akiyama,[1] Joseph V. Bonventre,[2] Sadayoshi Ito,[1] Takaaki Abe.[1] *[1]Tohoku Univ, Japan; [2]Brigham and Women's Hospital.*

Background: Mitochondrial dysfunction causes various mitochondrial diseases and kidney injuries. Anti-oxidant quinones have been used clinically to prevent the disease progression but the effectiveness is yet to be established. We recently found that an indole-derivative increased ATP levels in Hep3B cells and analyzed 41 newly synthesized indole derivatives. Among those compounds, we focused on the most potent derivative #5(MA-5). The aim of this study was to clarify the effects of MA-5 in mitochondrial diseases and kidney injury.

Methods: Fibroblasts from patients with mitochondrial diseases (Leigh syndrome,MELAS,Leber disease,and Kearns-Sayersyndrome)were cultured in ROS generating condition with BSO(L-buthionine-(S,R)-sulfoximine)andcell viabilities, cellular ROS and glutathione levels were measured. The redox property of MA-5 was examined by cyclic voltammetry. The site of MA-5 distribution was visualized by fluorescence-labeled MA-5(MA-5 FL). MA-5 was administrated, at 50mg/kg body weight by gavage, to mice 3 hr before they were exposed to kidney ischemia (26 min) reperfusion injury (IRI) or cisplatin (20 mg/kg body weight). Plasma creatinine (Cr), blood urea nitrogen (BUN) and renal pathology were assessed.

Results: MA-5 improved cell viabilities in a dose dependent manner in mitochondrial disease fibroblasts. MA-5 exhibited irreversible oxidation peaks by cyclic voltammetry, suggesting that MA-5 did not have antioxidant property like anti-oxidant quinones. MA-5 did not affect the cellular ROS or GSH levels. MA-5 FL co-localized with the mitochondrial marker, mitotracker. In IRI, Cr at 48 hr after ischemia (0.88 + 0.38 mg/dl vs 1.60 + 0.66, control) and tubular cell injury were significantly reduced in MA-5-treated group. BUN (70.9 + 10.1 vs 101 + 13.0 mg/dl) and tubular injuries, at 96 hr after cisplatin injection, were significantly reduced in Indole #5 treated groups.

Conclusions: MA-5 exhibited therapeutic effects in fibroblasts from mitochondrial disease patients as well as renoprotective effects in both IRI and cisplatin nephrotoxicity.

Mechanism of 5-Hydroxytryptamine 1F Receptor Stimulation of Mitochondrial Biogenesis in the Kidney Whitney Sharee Gibbs, Craig Cano Beeson, Rick G. Schnellmann. *Dept of Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: Pharmacological induction of mitochondrial biogenesis (MB), the process of creating new mitochondria to replace damaged mitochondria, is a potential therapeutic target for AKI. Our laboratory has demonstrated that LY344864, a selective 5-HT_{1F} receptor agonist, promotes recovery from AKI as demonstrated by an increase in MB and decreased BUN and Kim-1 in a mouse model of ischemia/ reperfusion AKI. While the 5-HT_{1F} receptor is a G_i- coupled GPCR, the mechanism of 5-HT_{1F} receptor mediated MB is unknown.

Methods: Mitochondrial respiration was measured in renal proximal tubule cells (RPTC) using a Seahorse XF Extracellular Flux Analyzer. Signaling pathways were explored using pharmacological inhibitors and immunoblot analysis.

Results: LY344864 (10 nM) increased FCCP-uncoupled respiration in RPTC, a marker of MB. LY344864 induced FCCP-uncoupled respiration was attenuated by pretreatment with gallein, L-NAME, and ODQ, pharmacological inhibitors of $G_{\beta\gamma}$, nitric oxide synthase, and soluble guanylyl cyclase, respectively. LY344864 upregulated p-Akt and p-eNOS protein expression after 15 min and 1 hr exposures, respectively. Gallein blocked increases in both p-Akt and p-eNOS following LY366864 treatment. Following pretreatment with MK2206, an Akt inhibitor, the increase in p-eNOS protein expression was attenuated.

Conclusions: This study reports the novel finding that $G_{\beta\gamma}$ heterodimer initiates MB and does so through a new pathway. Specifically, 5-HT_{1F} stimulation of $G_{\beta\gamma}$ activates Akt and eNOS, leading to the induction of MB. The identification of this pathway provides additional therapeutic targets for a drug intervention which could treat AKI.

FR-PO238

Formoterol Induces Renal Mitochondrial Biogenesis Through Gβγ-Dependent Signaling Robert Bruce Cameron, Craig Cano Beeson, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: Acute kidney injury (AKI) carries a high morbidity and mortality with no effective treatments beyond renal replacement therapy. AKI is characterized by mitochondrial dysfunction, particularly in the renal proximal tubule cells (RPTC). The induction of mitochondrial biogenesis (MB) is a therapeutic target for AKI. Our group has shown that formoterol, a β_2 adrenoceptor agonist, can induce MB in vitro and in vivo, and stimulate recovery of mitochondrial and renal function following AKI in mice. However, the signaling events leading to formoterol-induced MB remain unknown.

Methods: RPTC were pretreated with DMSO, 100 nM gallein, 10 μM L-NAME, or 100 nM MK2206 for 30 min and then treated with formoterol (30 nM). FCCP-uncoupled oxygen consumption rates (FCCP-OCR) were measured using the Seahorse XF-96 analyzer and protein phosphorylation was determined by immunoblot analysis.

Results: Formoterol increased Akt phosphorylation in RPTC at 30 min, and this increase was attenuated by the $G_{\beta\gamma}$ inhibitor gallein. Gallein also attenuated formoterol-induced increases in FCCP-OCR, a biomarker of MB. Formoterol increased the phosphorylation of eNOS, a downstream target of Akt, at 1 hr, and pretreatment with the Akt inhibitor MK2206 blocked Akt and eNOS phosphorylation. Additionally, treatment with the NOS-inhibitor L-NAME attenuated formoterol-induced increases in FCCP-OCR.

Conclusions: This study demonstrates that formoterol-induced MB occurs via b_2-adrenoceptor coupling to $G_{\beta\gamma}$. $G_{\beta\gamma}$ leads to the activation of Akt and eNOS, promoting MB. Stimulation of these signaling pathways represents an attractive therapeutic target for AKI.

FR-PO239

Identification of Slow-Cycling Cells in the Kidney Using TetOP-H2B-GFP Mice Shunsuke Takahashi, Akito Maeshima, Masao Nakasatomi, Hidekazu Ikeuchi, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura, Yoshihisa Nojima. *Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: Renal tubular epithelium can regenerate after a variety of insults. During tubular regeneration, survived tubular cells proliferate, migrate and differentiate into mature tubular epithelum. Using BrdU pulse/chase method, we previously reported that slow-cycling cells (label-retaining cells: LRCs) are present in renal tubules and act as the source of regenertaing cells after renal ischemia (JASN 14:3138-46. 2003). However, it is difficult to isolate and characterize LRCs in vitro, because there is no LRCs specific markers idenitified. In this study, we utilized the transgenic mice with doxycycline-inducible expression of an H2B-GFP fusion protein (TetOP-H2B-GFP mice), in which dividing cells can be labeled with GFP under doxycycline control.

Methods: TetOP-H2B-GFP mice were treated with doxycycline for the indicated periods (pulse). After several chase periods, kidneys were removed for analysis. Localization of GFP-positive cells was examined by immunostaining with several nephron markers and their cell number was quantitatively assessed.

Results: 1) After a pulse of doxycycline, GFP-positive cells were found in the kidney of TetOP-H2B-GFP mice. Most GFP-positive cells were AQP-1-positive tubular cells. 2) As pulse periods become longer, the number of GFP-positive tubular cells increased (pulse 8h-0.5%, pulse 24h-10%, pulse 72h-18%, pulse 1 week-40%, pulse 3 weeks-50%). 3) After a short pulse (8h) of doxycycline with no chase, all GFP-positive cells were present as a single cell, but after 2 weeks or 4 weeks chase periods, GFP-positive cells were found in clusters of two cells or three cells. 4) In TetOP-H2B-GFP mice treated with a long pulse (3 week) of doxycycline, the number of GFP-positive cells decreased according to chase periods (Chase 0w-50%, Chase 4w-40%, Chase 8w-5%).

Conclusions: These data suggest that slow-cycling cells can be detected as GFP-positive cells using TetOP-H2B-GFP mice under doxycycline control. This model will be applicable for selective isolation and in vitro characterization of slow-cycling tubular cells.

FR-PO240

Renal ERK1/2 Regulates PGC-1a and Mitochondrial Biogenic Homeostasis Physiologically and During Renal Injury Justin B. Collier, Ryan Whitaker, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: Acute kidney injury (AKI) is defined as a sudden decline in kidney function and the outcomes of AKI have not changed in the past few decades. Previous studies demonstrated that persistent disruption of mitochondrial homeostasis (e.g. peroxisome proliferator-activated receptor gamma coactivator-1a (PGC-1a), a master regulator of mitochondrial biogenesis (MB)), is an important contributor to renal ischemia reperfusion (IR) injury and repair. While the MAPK extracellular-regulated kinases 1/2 (ERK1/2) regulates numerous cell signaling pathways, the role of ERK1/2 activation in MB physiologically and as a consequence of renal IR injury remains limited.

Methods: Renal proximal tubule cells (RTPC) were treated with the specific MEK1/2 inhibitor trametinib (10nM) for various time points. Control mice were treated with trametinib (1mg/kg). Trametinib was administered 1 hour before 18 min of bilateral IR. Signaling pathways were explored using qRT-PCR and immunoblot analysis.

Results: Trametinib blocked ERK1/2 phosphorylation in RPTC within 10 min that continued for 24 hr. Trametinib also inhibited ERK1/2 phosphorylation *in vivo* at 4 and 24 hr. Trametinib increased PGC-1a mRNA at 1, 4, and 24 h in RPTC. The mRNA levels of PGC-1a target genes NDUFS1, NRF1, and TFAM increased at 1, 4, and/or 24 h after ERK1/2 inhibition in RPTC. Trametinib administered to control mice increased PGC-1a, NRF1, and TFAM mRNA at 4 h in the renal cortex and increased PGC-1a and TFAM protein. In the IR AKI model, pERK1/2 increased 4-fold at 1 and 3 h post IR. Increased pERK1/2 was linked to decreased mRNA levels of PGC-1a, NRF1, TFAM, and NDUFS1. Trametinib treatment attenuated suppression of mRNA PGC-1a and NRF1 at 3 h, increased TFAM protein 2.5-fold, and attenuated renal dysfunction as measured by BUN and KIM-1.

Conclusions: ERK1/2 downregulates renal mitochondrial homeostasis under physiological conditions and ERK1/2 inhibition during renal IR promotes recovery of PGC-1α and MB, and contributes to both mitochondrial and renal recovery. These results reveal a novel target for pharmacological intervention in AKI.

FR-PO241

The Guanylyl Cyclase Activator BAY 58-2667 Stimulates Mitochondrial Biogenesis and Promotes Recovery from Ischemia-Reperfusion Induced AKI Ryan Whitaker, Rick G. Schnellmann. *Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.*

Background: Mitochondrial dysfunction is an important pathophysiological component of acute kidney injury (AKI). As reduced mitochondrial function can impair energy-dependent renal repair processes following AKI, stimulation of mitochondrial biogenesis (MB), the generation of new, functional mitochondria, could promote renal recovery. We explored the efficacy of the guanylyl cyclase activator, BAY 58-2667, to induce MB and promote renal recovery following ischemia-reperfusion (I/R)-induced AKI.

Methods: Mitochondrial respiration was measured in primary renal proximal tubules cells (RPTC) using the Seahorse XF96 Extracellular Flux Analyzer. I/R injury was induced in male C57BL/6 mice aged 8-10 weeks by bilateral clamping of the renal pedicle for 19 minutes. Mice received daily treatment with saline vehicle or BAY 58-2667 (0.1 mg/kg) beginning at 24 h after I/R.

Results: Treatment of RPTCs with BAY 58-2667 increased FCCP-uncoupled respiration, a marker of MB. BAY 58-2667 also increased mitochondrial gene and protein expression, and mtDNA content in the renal cortex of naïve mice. Beginning 24 h after I/R injury, daily treatment with BAY 58-2667 accelerated recovery of renal function evidenced by reduced BUN and renal expression of NGAL and Kim-1 at 6 d. Histological examination demonstrated reduced renal tubular necrosis in BAY 58-2667 treated mice at 6 d. Furthermore, BAY 58-2667 decreased renal expression of the inflammatory cytokines TNF-α and IL-1β, and reduced oxidative DNA damage. These changes were associated with the recovery of renal MB signaling evidenced by increased mRNA expression of PGC-1α, NRF1, ND1, COX1 and ATPSβ, as well as mtDNA content and protein expression of PGC-1α and COX1. In addition, mitochondrial function was recovered as renal ATP returned to sham control levels. Finally, BAY 58-2667 blunted the progression of renal fibrosis evidenced by reduced COL1A2 and aSMA expression.

Conclusions: These data demonstrate that activation of guanylyl cyclase by BAY 58-2667 promotes recovery from AKI by stimulation of MB, reduction of inflammatory and oxidative damage, and inhibition of renal fibrosis.

Adult Human Renal Papilla CD133$^+$ Cells Improve Erythropoietin Production, Show Long Term Engraftment and Repair Glycerol-Induced Kidney Injury in SCID Mice Shikhar Aggarwal,[1] Cristina Grange,[2] Benedetta Bussolati.[1] *[1]Dept of Biotechnology and Health Sciences, Univ of Turin, Turin, Italy; [2]Dept of Medical Sciences, Univ of Turin, Turin, Italy.*

Background: Acute kidney injury (AKI) often involved deregulation of erythropoietin (EPO) production in the kidney. Novel treatment foresees introduction of cell therapies or strategies involving pharmacological modulations of intrinsic populations to produce EPO and repair of renal injury. CD133$^+$ adult human renal cells have been identified by our group as a promising adult renal progenitor cell. Of note, papillary CD133$^+$ cells show activation of hypoxia-inducible genes and are specifically involved in EPO production. However, their role in EPO production and fate to repair renal injury for long time has not yet been deconstructed in mice.

Methods: AKI is induced in immunodeficient mice using glycerol (8mg/gbw, i.m.) and adult human CD133$^+$ papillary cells (0.5 million cells per mice) are injected (*i.v.*) 1 day after the injury. Mice are euthanized at different time intervals (day 15/day 30) and blood and other tissues (kidneys, lungs, liver) are collected for EPO, creatinine/urea, histological/morphological analysis and molecular analysis (RNA, DNA and protein) respectively.

Results: Data showed that adult human CD133$^+$ papillary cells improve EPO production (of both human and mice origin) in the injured mice and protect against AKI in mice at day 15 and day 30 as compared to control group. The group of injured mice that received cells showed higher level of human and mice specific EPO, lower level of creatinine and urea in serum, lower level of kidney injury marker, KIM-1 and improved histology. CD133$^+$ papillary cells also reduced development of fibrosis in the injured tissues during repair (as shown by lower expression of alpha-SMA, profibrotic gene TGF-β and trichromic stain). In addition, immunohistochemical and fluorescence studies show localization of CD133$^+$ papillary cells within interstitium and tubules of the injured renal tissues.

Conclusions: Thus, our data supports that these CD133$^+$ papillary cells may provide an important source of EPO stimulation *in situ* and repair.

Early Mesenchymal Stem Cell Administration Prevents Acute Kidney Injury Superimposed on Chronic Kidney Disease in Rats and High Risk Patients Anna Gooch,[1] Nicole Molin,[1] Ping Zhang,[1] Zhuma Hu,[1] Christof Westenfelder.[1,2] *[1]Medicine, U of Utah and VAMC, Salt Lake City, UT; [2]Physiology, U of Utah, Salt Lake City, UT.*

Background: We showed that ischemic-reperfusion injury (I/R) causes renal and urine levels of the chemokine SDF-1 (CXCL12) to rise significantly within ~ 2 hrs. This rise mediates the homing of infused, CXCR4 (SDF-1 receptor)-expressing Mesenchymal Stem Cells (MSCs) to the sites of injury, where they act renoprotectively. CKD is a major risk factor for AKI. We tested here whether MSC administration is effective both in preventing I/R AKI superimposed on CKD and in arresting the AKI-induced further deterioration of CKD.

Methods: Rats: Groups of 6 rats underwent 5/6th Nephrectomy. Once CKD was established (~8 weeks), I/R AKI of the kidney remnant was induced and rats were treated either with vehicle or 2x10^6 MSC/kg bw, i.a. SCr and urine SDF-1/creatinine levels were assessed at pre- and post-operatively. **Patients:** 12 subjects with established CKD and at high risk for cardiac surgery associated AKI were treated i.a. with 2x10e6 MSCs per kg bw immediately post on-pump CABG or valve surgery. SCr and urinary SDF-1/creatinine levels were determined pre- and post-op. RIFLE criteria defined post-op AKI. Study subject data were compared to well-matched historical controls.

Results: Rats: MSCs significantly hastened improvement in AKI vs. controls. Urine SDF-1 levels remained low by 24 hrs in MSC vs. vehicle treated animals. **Patients:** No study subject had AKI at discharge, but 2 met post-op AKI Risk criteria. Urinary SDF-1/Cr ratios were significantly elevated at 2 and 6 hrs in subjects who developed AKI Risk, but remained stable in those who did not. In contrast to historical controls, 6 months post-op, no treated subject's CKD had worsened.

Conclusions: MSC administration offers renoprotection from AKI on CKD when given immediately post insult. Early, specific biomarker-guided diagnosis of AKI identifies the optimal time for MSC-based therapy. Another clinical trial in high-risk cardiac surgery patients showed that giving MSCs 24-48 hrs post insult, based on the late and non-specific rise in SCr, abolished their protective effects.

Improved Survival of Graft Bone Marrow-Derived Mesenchymal Stem Cells in the Ischemia-Reperfusion-Induced Injured Kidney with Overexpression of Heme Oxygenase-1

Nanmei Liu. *Jimin Hospital of Shanghai.*

Background: one marrow-derived mesenchymal stem cells (BMSCs) transplantation offers therapeutic potential for acute kidney injury (AKI), but with limited efficacy. This study investigated the effect of HO-1 overexpression on the donor BMSCs' survival, and its impact on the repair of AKI was also observed.

Methods: Ischemia/reperfusion (I/R)-AKI kidney homogenate supernatant (KHS) was prepared. SD BMSCs, eGFP-BMSCs and HO-1-BMSCs were harvested and treated by the AKI-KHS. Cell viability, apoptosis and cell cycle were evaluated. Activities of oxidant stress-related enzymes, expression of p65 and the protein levels of Caspase-3 and Bcl-2 in BMSCs were tested. Survivals of the implanting BMSCs in the AKI rat model as well as the renal function were also assayed.

Results: HO-1-BMSCs showed a high expression of HO-1 and AKI-KHS treatment further enhanced this level. This increased HO-1 expression promoted BMSCs survival under the AKI microenvironment with decreased apoptotic cells as well as less proportion of G0/G1 cells. AKI-KHS induced reduction of SOD activity and GSH-Px in BMSCs with increased MDA and XOD levels, however, HO-1 overexpression changed this phenomenon. Activation of NF-κB p65 was inhibited in HO-1-BMSCs. Western blot showed decreased Caspase-3 expression and increased Bcl-2 expression in HO-1-BMSCs. The in vivo study showed increased survival of HO-1-BMSCs in the AKI kidneys, which was associated with improved renal function.

Conclusions: HO-1 overexpression could enhance survival of BMSCs under the I/R-AKI microenvironment both in vitro and in vivo as the result of ROS elimination. Activity of NF-κB p65 and Caspase-3/Bcl-2 signal transduction pathways were involved in this process.

Induced Pluripotent Stem Cell-Conditioned Medium Mitigates Renal Ischemia-Reperfusion Injury by Suppressing Oxidative Stress

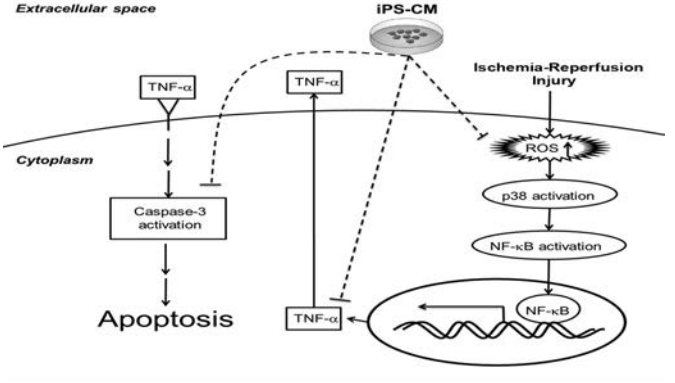
Wei-Cheng Tseng,[1] Der-Cherng Tarng.[2] *[1]Div of Nephrology, Dept of Medicine, Taipei City Hospital Heping-Fuyou Branch, Taipei, Taiwan; [2]Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Ischemic acute kidney injury (AKI) carries high mortality and current treatment remains unsatisfying. Induced pluripotent stem cell (iPS) is a promising therapeutic option for AKI; nonetheless, teratoma formation addresses critical safety concerns for iPS cell tranplantation. iPS-derived conditioned medium (iPS-CM) is comparable with iPS cells on ameliorating acute lung injury but the beneficial role of iPS-CM on AKI remains unclear.

Methods: Rat model of renal ischemia-reperfusion injury (IRI) and NRK52E cells subjected to hypoxia-reoyxgenation (H/R) were used to explore the role of iPS-CM on AKI. BUN, creatinine, tubular cell apoptosis, level of reactive oxygen species (ROS), expressions of proinflammatory cytokines and animal survival were investigated.

Results: Administration of iPS-CM intraperitoneally significantly improved renal function and decreased tubular cell apoptosis after renal IRI. Moreover, elevated ROS level in IRI-rat kidneys was markedly attenuated by iPS-CM. Co-culture of NRK52E cells with iPS-CM also significantly diminished H/R-induced apoptosis and ROS production. Furthermore, iPS-CM downregulated both H/R- and IRI-stimulated expressions of p38 MAPK, TNF-α, NF-κB and caspase 3. Additionally, the IRI-related IL-6 and MCP-1 expressions were also suppressed by iPS-CM. Finally, after being subjected to renal IRI, the rats treated with iPS-CM demonstrated better survival as compared those treated with phosphate-buffered saline or normal control medium.

Conclusions: iPS-CM decreases renal IRI-related lethality by suppressing ROS, inflammation, and tubular cell apoptosis. iPS-CM may be a potential therapeutic option for kidney repair in ischemic AKI.



FR-PO246

Vascular Adhesion Protein-1 (VAP-1) Inhibition Ameliorate Cisplatin Induced Acute Kidney Diseases and Disorders (AKD)

Daisuke Katagiri,[1,2] Yoshifumi Hamasaki,[1] Kent Doi,[1,3] Kousuke Negishi,[1] Takeshi Sugaya,[4] Masaomi Nangaku,[1,2] Eisei Noiri.[1] *[1]Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; [2]Apheresis and Dialysis, The Univ of Tokyo, Tokyo, Japan; [3]Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; [4]CMIC Ltd, Tokyo, Japan.*

Background: Cisplatin (CP) is a platinum compound that is used as an effective chemotherapeutic agent for many malignancies. Its nephrotoxicity is dose dependent, which often limits its administration. Research in the field of acute kidney diseases and disorders (AKD), including acute kidney injury (AKI), is important to prevent their progression to chronic kidney disease (CKD).

Methods: A new clinically relevant animal model using multiple low doses of CP was used to evaluate AKD. Human liver fatty acid-binding protein (L-FABP) transgenic (Tg) mice were administered 10 mg/kg of CP (three times, at 0, 1, 3 weeks) for four weeks. Vascular adhesion protein-1 (VAP-1) inhibitor that was recently reported to prevent fibrosis in organs was studied in this model. For treating group, mice received 2 mg/kg/day of PXS-4728A, a selective VAP-1 inhibitor, starting 3 weeks after the first CP administration.

Results: Moderate renal interstitial fibrosis occurred with multiple CP administration. Urinary L-FABP, one of the promising AKI biomarkers, increased about 10-fold one week after every CP injection. Although no further elevation of L-FABP was observed at 3W, following the omission of CP at 2W, L-FABP did not revert to baseline levels. Treatment of PXS-4728A for one week attenuated interstitial fibrosis in this model. VAP-1 inhibitor treatment remarkably reduced 4-HHE- and 8-OHdG-positive areas. The mRNA expressions of TGF-β, α-SMA, VEGF, and MCP-1 in the kidney were increased significantly by multiple CP treatments and attenuated by VAP-1 inhibitor treatment. Further, the inhibition of lipid accumulation in the S3 segments, together with L-FABP suppression was confirmed.

Conclusions: Multiple treatments with CP lead to moderate kidney dysfunction with increased biomarkers and renal fibrosis. As a standing point of onco-nephrology, VAP-1 inhibitors are promising candidates for the prevention of CKD in patients using CP for the treatment of malignancy.

FR-PO247

Pulsed Focused Ultrasound Improves Mesenchymal Stem Cell Therapy for Acute Kidney Injury by Upregulating Renal Interferon-Gamma to Stimulate Stem Cell Production of Interleukin-10

Scott R. Burks, Matthew Nagle, Michele Bresler, Saejeong Kim, Blerta Milo, Joseph A. Frank. *Frank Lab, NIH Clinical Center, Bethesda, MD.*

Background: Pulsed focused ultrasound (pFUS) to kidneys enhances mesenchymal stem cell (MSC) homing to kidneys and improves outcomes when treating early *or* established acute kidney injury (AKI) compared to MSC infusions alone. However, mechanisms of improved combination therapy are unclear.

Methods: AKI was induced in C3H or interferon-γ (IFNγ)-deficient mice with cisplatin (15 mg/kg). pFUS (40W, 5%dc) was delivered to kidneys ~3hr before infusion of 10^6 human MSC. MSCs were observed by immunostaining for human mitochondria. For some experiments, MSCs were treated in culture with recombinant INFγ or siRNA against IL-10. Cytokines were analyzed by mouse- and human-specific ELISAs. Serum creatinine and blood urea nitrogen values were measured spectraphotometrically.

Results: Proteomic profiling of AKI kidneys revealed that pFUS upregulated renal IFNγ and after MSC homed to pFUS-treated kidneys, they produced more human IL-10 compared to MSC in kidneys without pFUS. pFUS+MSC in IFNγ-ko mice led to greater MSC homing to pFUS-treated kidneys, but MSCs failed to produce greater IL-10 and pFUS+MSC yielded identical outcomes as MSC alone (ie, no improvement from pFUS+MSC). Supplementing MSC with IFNγ improved AKI outcomes in C3H mice in the absence of pFUS, while the improved outcomes seen pFUS+MSC were abrogated by knocking down IL10 in MSC.

Conclusions: pFUS pretreatment of kidneys during AKI alters the renal molecular environment to increase MSC homing to treated kidneys. However, improved disease outcomes from combination therapy are the result of pFUS upregulating IFNγ in the kidney so that MSCs homing to pFUS-treated kidneys are subsequently conditioned to produce more IL10, which has been shown to improve AKI.

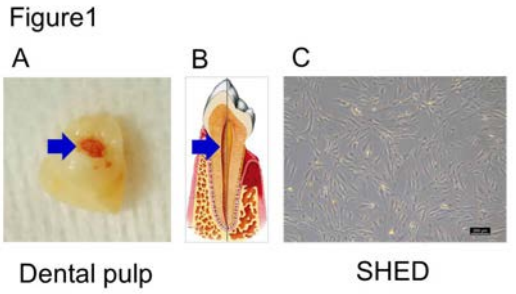
FR-PO248

Stem Cells from Human Exfoliated Deciduous Teeth Ameliorate Acute Kidney Injury in Mice

Yuka Hattori,[1] Hangsoo Kim,[2] Naotake Tsuboi,[2] Akihito Yamamoto,[1] Seiichi Matsuo,[2] Shoichi Maruyama.[2] *[1]Oral and Maxillofacial Surgery, Nagoya Univ Graduate School of Medicine, Japan; [2]Nephrology, Nagoya Univ Graduate School of Medicine, Japan.*

Background: Preclinical studies have indicated that administered mesenchymal stem cells (MSCs) ameliorated various types of renal injury and promoted the subsequent kidney repair. Recently, stem cells from human exfoliated deciduous teeth (SHED), which has been discarded as a medical waste, has received attention as a novel kind of MSCs.



The purpose of this study is to clarify the therapeutic effects of SHED on AKI induced by IRI.

Methods: Seven days after heminephrectomy, the renal artery and vein were clamped for 20 min to induce ischemia in male C57BL/6 mice. SHED or PBS as a control was administered into subrenal capsule right after the reperfusion. Blood, urine and tissue samples were collected. In order to confirm renoprotective potential of conditional media of SHED (SHED-CM) *in vitro*, H_2O_2 stimulation assay and scratch wound assay using mouse tubular epithelial cells (TECs) were also performed.

Results: Serum creatinine and BUN levels and urinary Kim-1 excretion were significantly decreased in SHED-treated group. Inflammatory cell infiltrations and inflammatory cytokine/chemokine concentrations of kidneys were significantly reduced in SHED-treated group. In *in vitro* assay, MCP-1secreted from TEC wasreduced andTEC proliferation and migration were significantly promoted by SHED-CM treatment.

Conclusions: In the present study, SHED administration successfully attenuated mouse IRI-induced AKI. Our results indicate that SHED exerted anti-inflammatory activity in early stage of inflammation and promote cell proliferation by paracrine effect, thereby renoprotective effect in a mouse model of ischemic kidney injury. These results suggest that SHED might offer novel stem cell resource, which can be applied for the treatment of ischemic kidney injury.

FR-PO249

Endothelial Autophagy and Endothelial-to-Mesenchymal Transition (EndoMT) in eEPC Treatment of Ischemic AKI Daniel Patschan, Susann Patschan, Gerhard A. Mueller. *Clinic of Nephrology and Rheumatology, Dept of Internal Medicine, Göttingen, Nierdersachsen, Germany.*

Background: Autophagy potentially prolongs the cellular lifespan. Early Endothelial Progenitor Cells (eEPCs) protect mice from ischemic AKI. The mid-term prognosis in AKI critically depends on vascular rarefication and interstitial fibrosis with the latter partly being induced by mesenchymal transdifferentiation of endothelial cells (EndoMT). Aim of the study was to determine the impact of eEPC preconditioning with different autophagy inducing agents (SAHA / Temsirolimus - Tems) in ischemic AKI.

Methods: Male C57/Bl6N mice were subjected to bilateral renal ischemia (40 minutes). Animals were injected with either untreated of SAHA- or Temsirolimus-pretreated syngeneic murine eEPCs at the time of reperfusion. Mice were analyzed 48 hours and 4 weeks later. In addition, cultured eEPCs were treated with TGF-β +/- SAHA, autophagy (perinuclear LC3-II) and Stress Induced Premature Senescence (SIPS - SA-b-Gal) were evaluated 96 hours later.

Results: Cultured eEPCs showed reduced perinuclear density of LC3-II+ vesicles and elevated levels of SA-b-Gal after treatment with TGF-β alone, indicating impaired autophagy and aggravated SIPS. These effects were completely abrogated by SAHA. Systemic administration of either SAHA or Tems pretreated eEPCs resulted in elevated intrarenal endothelial p62 at 48 h and 4 weeks. This effect was most pronounced after injection of SAHA treated eEPCs. At 4 weeks endothelial expression of mesenchymal aSMA was reduced in animals receiving untreated and SAHA pretreated cells. In addition, SAHA treated cells reduced fibrosis at week 4. Tems in contrast aggravated EndoMT. Postischemic renal function declined after renal ischemia and remained unaffected in all experimental cell treatment groups.

Conclusions: In ischemic AKI, intrarenal endothelial autophagy may be stabilized by systemic administration of pharmacologically preconditioned eEPCs. Early EPCs can reduce postischemic EndoMT and fibrosis in the mid-term. Autophagy induction in eEPCs my either increase or decrease the mesenchymal properties of intrarenal endothelial cells. Thus, endothelial autophagy induction in ischemic AKI is not a renoprotective event per se.

FR-PO250

Impact of Timing Administration of Mesenchymal Stromal Cells on Serum Creatinine following Renal Ischemia/Reperfusion in Rats Pauline Erpicum,[1,2] Pascal Rowart,[2] Laurence Poma,[2] Jean-marie H. Krzesinski,[1,2] Oliveir Detry,[3] Francois Jouret.[1,2] *[1]Nephrology, Univ of Liege Hospital (ULg CHU), Liege, Belgium; [2]GIGA Cardiovascular Sciences, Univ of Liege, Liege, Belgium; [3]Abdominal Surgery and Transplantation, Univ of Liege Hospital (ULg CHU), Liege, Belgium.*

Background: Experimental models of renal ischemia/reperfusion (I/R) have suggested protective effects of mesenchymal stromal cells (MSC) therapy. Still, parameters of MSC injection, including volume, route and timing of cell administration, remain largely debated. Particularly, MSC infusion in mouse has been shown to be beneficial "a priori" but deleterious "a posteriori" of renal I/R injury.

Methods: In order to further investigate the influence of the timing of MSC administration, we used 10-week-old Lewis rats categorized in 4 groups. Groups 1 (MSC D-7, n=10) and 2 (MSC D+1, n=7) received caudal i.v. injection of MSC ($1,5x10^6$ in 1 mL of saline) 7 days before or 1 day after renal I/R, respectively. Control groups 3 (saline D-7, n=6) and 4 (saline D+1, n=6) received equal volume of saline at similar time points. Left renal ischemia (by clamping of the renal pedicle) lasted 45 minutes. Right nephrectomy was simultaneously performed. Blood sample was collected from inferior vena cava at 48 hours post reperfusion. MSC phenotype was confirmed by FACS analysis.

Results: In groups 1 and 3, serum creatinine (SCr) reached 1.4 ± 0,7 *versus 2,4 ± 0,8 mg/dL, respectively ($p<0.05$). In groups 2 and 4, SCr was 4,9 ± 0,7 versus* 3,3 ± 0,9 mg/dL, respectively ($p<0.001$). Furthermore, SCr levels were statistically worse when MSC were administered after renal I/R in comparison to a priori infusion ($p<0.0001$).

Conclusions: MSC administration 7 days prior to renal I/R may attenuate kidney injury in comparison to (i) saline infusion or (ii) MSC infusion 1 day after renal I/R. Conversely, on the basis of SCr levels, MSC therapy performed after renal I/R worsens kidney injury in rats.

Cytosolic Phospholipase A2 Regulates the G2 to M Transition by Modulating the Activity of Tumor Suppressor Sirtuin 2 Said Movahedi naini, Joseph V. Bonventre. *Brigham and Women Hospital, Renal Division, Boston, MA.*

Background: SIRT2, a tumor suppressor gene, contributes to the control of the G2 to M transition checkpoint of the cell cycle under cellular stress. However, the mechanisms underlying both SIRT2 activation and the regulation of the G2 to M transition remain largely unknown. Here, we describe the regulatory function of $cPLA_2\alpha$ on SIRT2 activity and the G2/M transition.

Methods: G2 to M transition in vitro was evaluated in LLC-PK1 cells overexpressing SIRT2 or $cPLA_2\alpha$ and in mouse embryonic fibroblasts (MEFs) derived from cpla2α-/- mice. G2 to M transition in vivo was assessed in *$cpla_2\alpha$*-deficient mice during moderate IRI and under mitotic stress induced by colchicine. G2 and mitotic cells were identified by staining with pH3 and MPM-2 antibodies, respectively. Analysis of the phosphorylation state of SIRT2 was carried out in the presence or absence of $cPLA_2\alpha$ in vitro by kinase assay and in vivo using a SIRT2 ser331 phosphospecific antibody.

Results: $cPLA_2\alpha$, SIRT2, and cyclin A-Cdk2 form a multiprotein complex at the G2/M transition in vivo and in vitro. $cPLA_2\alpha$ acts as a bridge in this complex to promote binding of SIRT2 to cyclin A-Cdk2. Cyclin A-Cdk2 then phosphorylates SIRT2 at ser331. Phosphorylation of SIRT2 at ser331 diminishes its catalytic activity and reduces its binding affinity to centrosomes and mitotic spindles. This detachment of SIRT2 from mitotic spindles in the presence of $cPLA_2\alpha$ promotes G2 to M transition. In *$cpla_2\alpha$*-/- MEFs and kidney tubular cells SIRT2 was hypophosphorylated at the G2/M transition. Lack of $cPLA_2\alpha$ in these cells resulted in a reduction in the number of mitotic cells in response to mitotic stress.

Conclusions: $cPLA_2\alpha$ isa regulator of the G2 to M transition in vitro and during ischemia/reperfusin injury in kidney epithelial cells. This function of $cPLA_2\alpha$ may be further exploited to better understand the important link between $cPLA_2\alpha$ and tumorigenesis and between inflammation and the age-related disorders such as Alzheimer's disease, in which SIRT2 has been implicated.

The Cytohesin Guanosine Exchange Factors Are Required to Promote HGF-Mediated Renal Recovery After Acute Kidney Injury in Mice Lorraine C. Santy, Marta Reviriego-Mendoza. *Dept of Biochemistry and Molecular Biology, Pennsylvania State Univ, Univ Park, PA.*

Background: The lack of current treatment and preventable measures for acute kidney injury (AKI) in hospitalized patients results in an increased mortality rate of up to 80% and elevated health costs. The molecular aspects of kidney injury and repair are still uncertain. Hepatocyte growth factor (HGF) promotes recovery of the injured kidney by inducing survival and migration of tubular epithelial cells to repopulate bare tubule areas. HGF-stimulated kidney epithelial cell migration requires the activation of ADP-ribosylation factor 6 (Arf6) and Rac1 via the cytohesin family of Arf-guanine-nucleotide-exchange-factors (GEFs), *in vitro*.

Methods: We used an ischemia and reperfusion injury (IRI) mouse model to analyze the effects of modulating this signaling pathway on kidney recovery. We treated IRI mice with either HGF, the cytohesin inhibitor SecinH3, or a combination of both. Kidney function was assessed by measuring creatinine (Cre) and blood urea nitrogen (BUN) levels. Standard H&E staining was used to assess kidney structures and immunohistochemistry was performed to detect active-Rac1 and active-Arf6.

Results: Simultaneous treatment with SecinH3 and HGF blocks the ability of HGF to promote kidney recovery as evidenced by Cre and Bun levels. Immunohistochemistry showed that HGF treatment promoted recovery of tubule structure, and had enhanced levels of active, GTP-bound Arf6 and GTP-Rac1. SecinH3 treatment, however, caused a dramatic decrease in GTP-Arf6 and GTP-Rac1 levels when compared to kidney sections from HGF treated IRI mice. Additionally, SecinH3 counteracted the renal reparative effects of HGF.

Conclusions: We show that HGF-dependent damaged kidney recovery requires the function of a cytohesin-dependent signaling module, and that inhibiting cytohesins counteracts HGF-stimulated recovery. In addition, we demonstrate that HGF treatment of ischemic mice promotes the activation of Arf6 and Rac1 in the recovering kidneys in a cytohesin-dependent manner, and that cytohesin activity is required to promote epithelial repopulation of kidney tubules and thus kidney recovery.

Regulation of Kidney Injury Molecule-1-Mediated Efferocytosis by Rho GTPases Ola Ismail,[1] Xizhong Zhang,[2] Lakshman Gunaratnam.[1,2] *[1]Dept of Medicine, Western Univ, London, ON, Canada; [2]Matthew Mailing Centre and Lawson Research Inst, London Health Sciences Centre, London, ON, Canada.*

Background: Kidney injury molecule 1 (KIM-1) is a phagocytic receptor for apoptotic cells that is specifically upregulated on the apical membrane of proximal tubule cells (PTECs) after acute kidney injury. KIM-1-mediated clearance of apoptotic cells (efferocytosis) has been shown to protect from tissue damage during acute kidney injury by down-regulating innate immunity and inflammation. As cytoskeletal remodeling is essential for phagocytosis, we examined the relative importance of Rac1 and RhoA, two key Rho GTPases that mediate actin remodeling, in KIM-1-dependent efferocytosis. We also investigated a possible link between Ga12, which we previously identified as a KIM-1-interacting protein, and these Rho GTPases.

Methods: To study the role of Rac1 and RhoA in KIM-1-mediated uptake of apoptotic cells, we utilized chemical inhibitors or plasmids encoding dominant negative forms of Rac1 and RhoA proteins, and measured the uptake of apoptotic cells by flow cytometery. Using commercially available GTPase pull-down assays, we measured the endogenous Rac1 and RhoA activity in KIM-1-expressing cells after apoptotic cell-stimulation. To decipher whether these Rho GTPases are down-stream mediators of Ga12-KIM-1 signaling, we silenced Ga12 using siRNA and measured Rac1 and Rho GTPase activity.

Results: Inhibition of Rac1 resulted in a significant decrease in KIM-1-mediated phagocytosis, whereas inhibition of and RhoA increased it. RhoA activity gradually increased during phagocytosis and peaked during the later stages of phagocytosis, whereas Rac1 activity remained constant over the entire course of phagocytosis. Furthermore, silencing a key KIM-1-interacting protein, Ga12, caused a significant decrease in RhoA activity.

Conclusions: We conclude that Rac1 and RhoA play opposing roles during KIM-1-mediated efferocytosis, where RhoA serves to mediate signaling by KIM-1 and its interacting partner, Ga12.

Periostin Induces Kidney Fibrosis After Ischemia-Reperfusion Injury via p38 MAPK Pathway Jung Nam An,[1,2] Seung Hee Yang,[3] Jin Ho Hwang,[4] Chun Soo Lim,[1,2] Yun Kyu Oh,[1,2] Yon Su Kim,[2] Jung Pyo Lee.[1,2] *[1]Seoul National Univ Boramae Medical Center; [2]Seoul National Univ Hospital; [3]Seoul National Univ Kidney Research Inst; [4]Chung-Ang Univ Hospital, Republic of Korea.*

Background: Periostin, a matricellular protein, has been reported to play a crucial role in inflammatory and fibrotic mechanism. We hypothesized that periostin involves in the progression of acute kidney injury to kidney fibrosis.

Methods: To establish a kidney progression model, we induced unilateral ischemia-reperfusion injury of left kidney pedicle for 30minutes in wild type (WT) C57BL/6 mice and *Postn null*mice (*Postn*$^{-/-}$), and observed during 4 to 6 weeks. In addition, inner medulla collecting duct cell line was subjected to put in the hypoxic incubator (1% O_2, 5% CO_2, and 94% N_2) for 24 and 72 hours.

Results: After 4 to 6 weeks, the left kidneys in *Postn null* mice were significantly less atrophied and less small in weight compared to those of WT mice. Apparent tubular atrophic changes and collagen fiber deposition, and expressions of collagen I, S100A4, and periostin were also remarkably alleviated in *Postn null* mice compared within WT mice. Furthermore, the expressions of phosphorylated p38 mitogen-activated protein kinase (p-p38 MAPK) and cleaved caspase-3 were significantly decreased in *Postn null* mice compared to in WT mice. *Postn null* mice also attenuated intra-kidney mRNA expression of fibrosis markers, p53, caspase 9, and p-p38 MAPK. *In vitro,* hypoxic injury during 72 hours resulted in cellular morphologic changes and increased the expressions of several fibrosis markers, periostin, and p-p38 MAPK. Treatment of recombinant periostin in hypoxic condition magnified the cellular changes and the expression of p-p38 MAPK, which were comparable to treatment with transforming growth factor-β1. In contrast, inhibition of p38 MAPK attenuated the periostin induced inflammation and fibrosis.

Conclusions: In conclusion, periostin is related to the progression via p38 MAPK pathway to kidney fibrosis following acute kidney injury triggered by hypoxic or ischemic insult. Periostin ablation could have protective effects in kidney progression.

FR-PO255

Tim-3/Gal-9 Pathway Activation Ameliorates Renal Ischemia Reperfusion Injury by Shifting the Balance of Activated CD4$^+$ T Cell Immune Response in Mice Yamei Wang, Yuhong Tao. *Dept of Pediatrics, West China Second Univ Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: Renal ischemia reperfusion injury (IRI) is characterized by kidney inflammation. Galectin-9 (Gal-9) is identified as a T-cell immunoglobulin domain and T mucin domain protein-3 (Tim-3) ligand, and Tim-3/Gal-9 interaction acts as a specific inhibitor of immune response. The purpose of this study was to study whether activation of Tim-3/Gal-9 pathway can ameliorate renal IRI by shifting the balance of activated activated CD4$^+$T cell immune response in mice.

Methods: Expression of renal Gal-9 and Tim-3 were detected in mice with left renal IRI at baseline, day 3,10. The percentage of Th1, Th17 and Foxp3$^+$Tregs and their mRNA expression in kidney were measured.rAAV9 carryingGal-9 was injected to mice two weeks before kidney IRI to overexpress Gal-9 and activate Tim-3/Gal-9 pathway. Then, CD4$^+$T cell subsets and cytokines in kidney were evaluated at day 3 and 10.

Results: The expression of Gal-9 and Tim-3 in IR kidney at day3 and 10 increased ($P<0.05$). The percentage of Foxp3$^+$Treg in CD4$^+$T cells and Foxp3 mRNA was up-regulated with time. Compared with normal control kidney, the mRNA levels of Foxp3, Gal-9 and Tim-3 of kidney at day 3, 10 after renal IRI were increased in IRI kidney. Compared with empty virus group at 3 days and 10 days after IRI, over-expression of Gal-9 can reduce tubular damage in the healing phase of renal IRI. Protein plex results showed that the expression levels of inflammatory cytokines including TNF-α, IFN-γ, IL-17 and IL-6 was decreased, while the expression level of IL-10 was increased. The mRNA level of Foxp3 in kidney, the percentage of Foxp3$^+$Treg cells in IRI kidneys was increased. However, the proportions of Thl, Thl7 cells and the gene levels of T-bet and RORyt were decreased. In the bilateral renal IRI model, the mice mortality was decreased after rAAV-Gal-9 intervention.

Conclusions: Tim-3/Gal-9 pathway activation can ameliorate kidney damage and increase survival rate of mice after renal IRI, inhibit Th1 and Th17 cell-mediated immune responses, and promote the proliferation of Foxp3$^+$Treg after renal IRI, which may be an important mechanism for renal protection of Gal-9 /Tim-3 pathway.

FR-PO256

Administration of an Inhibitor of IκB Kinase Inhibitor at 24 Hours After Acute Kidney Injury Improves Functional Recovery and Prevents Renal Fibrosis Florence Lilian Johnson,[1] Nimesh Patel,[1] Massimo Collino,[2] Christoph Thiemermann.[1] *[1]Translational Medicine and Therapeutics, The William Harvey Research Inst, Queen Mary Univ of London, London, United Kingdom; [2]Dept of Drug Science and Technology, Univ of Turin, Turin, Italy.*

Background: Acute kidney injury (AKI) is a major risk factor for the development of chronic kidney disease (CKD). Renal ischemia may cause post-inflammatory scarring leading to the loss of nephrons and the development of fibrosis. Nuclear factor kappa-B (NF-κB) is a family of transcription factors activated post-ischemia, but its role in the progression of AKI to CKD is unknown.

Methods: Male Wistar rats were subject to a RH nephrectomy and LH unilateral renal ischemia for 30 min, or nephrectomy only (sham) (n=8). Animals subject to ischemia (control animals) were allowed to recover and culled at 1 (n=4), 2 (n=4), 7 (n=4), 14 (n=4) or 28 (n=7) days (d) post reperfusion. A separate group of animals subjected to ischemia were administered IKK16, an inhibitor of IκB kinase (IKK), at 24h post AKI (1mg/kg i.v in 10% DMSO), and culled at 2 (n=4), 7 (n=8) or 28d (n=7).

Results: Compared to sham-operated rats, rats subjected to unilateral renal ischemia developed AKI (increases in serum creatinine and decreases in the estimated creatinine clearance). The delayed administration of IKK16 at 24h post AKI (at peak creatinine values) significantly improved renal functional recovery and structural injury at 48h post AKI. Compared to sham-operated rats, rats culled at 7d post AKI demonstrated significant increases in α smooth muscle actin (α-SMA) and CD68$^+$ staining for myofibroblasts and macrophages, respectively. IKK16 administration significantly decreased α-SMA and CD68+ staining at 7d post AKI. Rats culled at 28d post AKI demonstrated a significant increase in Sirius red staining compared to sham rats, indicating the development of fibrosis. Administration of IKK16 at 24h significantly attenuated Sirius red staining, and therefore the level of fibrosis at 28d.

Conclusions: Inhibition of IKK at 24h post AKI (at peak creatinine values) improves renal functional recovery at 48h post AKI, and reduces the degree of fibrosis observed at 28d.

FR-PO257

The Peroxisome Proliferator-Activated Receptor γ (PPAR-γ) Agonist Pioglitazone Prevents NF-κB Activation in Cisplatin Nephrotoxicity by Reducing p65 Acetylation Through AMPK-SIRT1/p300 Pathway Junhua Li, Ying Zhang, Jiong Zhang, Ying Yao, Gang Xu. *Dept of Nephrology, Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China.*

Background: NF-κB is a ubiquitously expressed transcription factor controlling the expression of numerous genes involved in inflammation. The aim of this study was to evaluate whether the activation of peroxisome proliferator-activated receptor-γ (PPAR-γ) could attenuate cisplatin-induced NF-κB activation in cisplatin nephrotoxicity.

Methods: Acute kidney injury model was established of by intraperitoneal injection of cisplatin. C57BL/6 mice were divided into three groups: normal group; model group; and treatment group, with pioglitazone gavage of three days. Respectively after injection in 24, 48 and 72 hours, the mice serum were collected for renal function and kidney specimen for pathological, Western blot, immunohistochemistry and real time PCR detection.

Results: Our results showed PPAR-γ agonist Pioglitazone could decrease the expression of NF-κB p65 transcription target genes such as pro-inflammation cytokines interleukin 6 (IL-6), interleukin-1 b(IL-1b), and tumor necrosis factor-a(TNF-α) and inhibit cell apoptosis and MPO infiltration in cisplatin nephrotoxicity. Suppressing NF-κB activity following Pioglitazone treatment was involved in inhibiting IκB-α degradation, phosphorylation modification and NF-κB p65 subunit translocation induced by cisplatin injection. The NF-κB p65 subunit translocation is dependent on p65 acetylation, which is mainly regulated by SIRT1 or p300. Of note, The subsequent AMP kinase (AMPK) activation not only decreases the p300 phosphorylation, activation and its interaction with p65, but also increases the SIRT1 expression, activation and binding to p65, leading to a significant reduction p65 acetylation. Interestingly, the reduction in expressions of IL-6, TNF-α and IL-1β, inhibition of cell apoptosis and MPO infiltration following Pioglitazone treatment in cisplatin nephrotoxicity were attenuated by the PPAR-gantagonist GW9662.

Conclusions: Our results suggest that PPAR-γ agonist Pioglitazone prevents NF-κB activation in cisplatin nephrotoxicity by reducing p65 acetylation through AMPK-SIRT1/p300 pathway.

Competitive Inhibition of CD95L Reduces Inflammation, but Only Modestly Improves Outcomes in Experimental Isquemia-Reperfusion Injury
Luis Eduardo Becker, Clara Daschner, Martin G. Zeier, Christian Morath. *Nephrology, Univ of Heidelberg, Heidelberg, Germany.*

Background: After previous encouraging results in CD95L (FasL) mutant mice in ischemia-reperfusion injury (I/R) models, we sought to investigate the effect of the competitive pharmacologic inhibition of CD95 (FAS) in kidney I/R using APG101, an orphan drug developed for the treatment of recurrent glioma, which has shown a good patient tolerability in phase I and II clinical studies.

Methods: C57BL/6 mice treated with different dosages of APG 101 (10, 30 or 100 µg/kg-body weight, single-dose, 12h before I/R) or vehicle (PBS) alone were submitted to a 30min bilateral renal I/R. Sham-op animals were either treated with the highest APG101 dose or PBS. The experiment was further divided into two observation periods: day 2 (injury phase) and day 7 (recovery phase). Serum and kidney tissue analysis were performed focusing on function recovery, cell proliferation, macrophage infiltration and relevant markers of the target pathway. Results are given as mean±SD.

Results: Optimal serum CD95L saturation was only achieved in the APG 100µg/kg group (98.4±0.35% and 96.9±1.3% at day 2 and 7, respectively), so that experiments were further conducted with this dosage. At day 2, serum creatinine was significantly higher in the I/R PBS group, but not in the I/R APG group compared to sham-op (0.26±0.12 and 0.20±0.07 vs. 0.09±0.03 mg/dl P<0.05), a similar pattern was seen in macrophage infiltration and MCL-1 mRNA expression in the kidney, both persisting until day 7. Apoptosis, however, was similar between the I/R groups in both observation periods. APG treatment markedly reduced cell proliferation in both sham and I/R animals compared to PBS (0.5±0.9 vs. 8.4±5.7 Ki67 positive cells/hpf, p=0.0004), which was observed at day 2, but didn't persist until day 7.

Conclusions: Despite an anti-inflammatory effect, the APG101-induced impairment of the tubular cell proliferation may have hampered the early recovery phase after I/R leading to the modest results.

FR-PO259

Oral Treatment with PBI-4050 Reduces Ischemia-Reperfusion-Induced Fibrosis
Jean-François Thibodeau, Mikaël Tremblay, Brigitte Grouix, Lilianne Geerts, Alexandra Felton, François Sarra-Bournet, Pierre Laurin, Lyne Gagnon. *ProMetic BioSciences Inc., Laval, QC, Canada.*

Background: PBI-4050, a novel first-in-class orally active compound which is currently in clinical phase Ib/II in CKD patients, displays antifibrotic activities via a novel mechanism of action. In a double-blind ascending dose (400 to 2400 mg) clinical phase I trial, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant side effects. Clinically, ischemia is a leading cause of acute kidney injury (AKI), which may result from a variety of conditions, such as decreased cardiac output, renal vascular occlusion or obstruction, and kidney transplantation. The aim of this study was to investigate the anti-fibrotic activity of PBI-4050 in a mouse model of acute ischemic kidney injury.

Methods: Renal ischemia-reperfusion (IR) injury was induced by the clamping of the left renal pedicle for 60 minutes in C57BL/6 mice (6-8 week old). Mice were treated with oral administration of vehicle or PBI-4050 (200 mg/kg) from day -3 to day 13 and sacrificed at day 14.

Results: Renal IR-injury induced a rise in serum creatinine at day 2 that was prevented by oral treatment with PBI-4050. At day 14, mice suffering from renal IR demonstrated a loss in hematocrit which was also prevented by PBI-4050 treatment. Furthermore, histomorphometric analysis demonstrated a significant increase in renal fibrosis, determined by medullary collagen accumulation in mice with IR-injury, which was significantly reduced by PBI-4050 treatment. In addition, PBI-4050-treatment reduced kidney type-III collagen mRNA expression.

Conclusions: Taken together, these pre-clinical results suggest that PBI-4050 offers the potential as a novel therapy for the treatment of AKI and may delay or prevent the onset of fibrosis in renal transplant recipients.

Cisplatin Acute Kidney Injury and Conversion to Chronic Kidney Disease
Robert L. Safirstein,[1,2] Heino Velazquez,[1,2] Richard Torres,[2] Gilbert W. Moeckel,[2] Gary V. Desir.[1,2] *[1]Nephrology, VACT HealthCare System, West Haven, CT; [2]Nephrology, Yale Univ, New Haven, CT.*

Background: Chronic Kidney Disease (CKD) develops in humans after repeated doses of cisplatin (CP). We report on a new model to investigate the mechanism of this form of CKD.

Methods: 8-week old C57Bl6 mice were given either a single or double dose (2 weeks apart) of CP (15 mg/kg) and studied 2,4,6,9 and 16-25 weeks after the first dose. GFR was measured by inulin clearance followed by intravascular perfusion-fixation. Immunohistochemistry and Multiphoton Microscopy (MPM) were applied to the fixed tissue.

Results: GFR fell precipitously to below 50% of controls 2 weeks after the second dose and progressed without hypertension, loss of glomerular number, or glomerulosclerosis. Kidney weight fell as a result of loss of cortical tissue. Collagen deposition increased but was mainly restricted to peritubular locations along the cortico-medullary region. Influx of macrophages, increased cell cycle activity (Ki67) and apoptosis (TUNEL) were followed by vascular rarefaction. Ki67 failed to increase after the second dose as it did after a single dose. The cyclin-dependent kinase inhibitor protein p21 increased and paralleled the lack of cell cycle activity. Abnormal glomerulotubular junctions (GTJ) developed only after the second dose, which included loss of megalin positive parietal epithelial cells and the formation of atubular glomeruli. These changes correlated well with the development of progressive renal insufficiency.

Conclusions: MPM uncovered abnormalities of the GTJ that marked the transition from AKI to CKD in CP-induced CKD. Coupled with the failure of the proximal tubule (PT) to re-enter the cell cycle suggests a causal relationship between failed repair of this segment and the conversion of AKI to CKD. The increased expression of the p21 gene seen here and its demonstrated role in progression in the renal ablation model of CKD suggests its sustained activation may cause the conversion of AKI to CKD. Understanding why injured PT cells fail to re-enter the cell cycle following the second dose of CP is likely to yield new means to prevent CP-induced CKD, which may be applicable to other forms of AKI to CKD conversion.

FR-PO261

The MEK1/2 Inhibitor, U0126, Decreases Cisplatin-Induced AKI and Slows Cancer Growth in Mice
Kameswaran Ravichandran, Abdullah Ozkok, Qian Wang, Alkesh Jani, Charles L. Edelstein. *Univ of Colorado Denver.*

Background: Nephrotoxicity is cisplatin's major dose-limiting side effect as a chemotherapeutic agent. We have developed a model of 4 week, low dose cisplatin (Cis)-induced AKI in mice with cancer. In the 4 week model of AKI, there is an increased ERK expression in kidneys.

Methods: Wild type C57BL/6 mice were injected subcutaneously with murine lung cancer cells derived from C57BL/6 mice. Ten days later, Cis (10 mg/kg/week) was given for 4 weeks. Mice were treated with the ERK inhibitor U0126 (5 mg/kg 2 times a week for 4 weeks).

Results: There was a significant decrease in BUN, SCr and serum NGAL in mice treated with Cis+U0126 vs. Cis only. Tumor weight and volume was decreased in mice treated with vehicle+U0126 vs vehicle alone demonstrating that U0126 decreases tumor growth. Tumor weight and volume was decreased in mice treated with Cisplatin+U0126 vs. Cisplatin alone demonstrating that U0126 significantly increased the therapeutic effect of cisplatin.

	Vehicle	Vehicle+ U0126	Cis	Cis+ U0126
BUN (mg/dL)	26.7	27.1	58.9*	40.1**
Scr (mg/dL)	0.1	0.1	0.3*	0.18***
sNGAL (ng/mL)	90 ± 13	185±34	569*	313**
Tumor weight (g)	1.8	1+	0.9+	0.5**
Tumor volume week 1 (mm3)	19	1	8	1.8
Tumor volume week 4 (mm3)	789	235+	341+	70++

N=11-15 per group. *P<0.01 vs. Vehicle. ** P<0.05 vs. Cis. *** P<0.05 vs. Cis, NS vs. vehicle. +P<0.01 vs Vehicle. ++P<0.01 vs. Vehicle and Cis

Conclusions: U0126 decreased cisplatin-induced AKI. In addition, U0126 decreased tumor growth and improved the therapeutic effect of cisplatin. Discovery of a drug that decreases cisplatin-induced AKI and improves the therapeutic effect of cisplatin would be a significant finding for patients with cancer.

Glycogen Synthase Kinase-3 Regulates Fibroblast Activation and Development of Fibrosis following Renal Ischemia/Reperfusion in Mice
Shailendra Pratap Singh,[1] Shixin Tao,[1] Timothy A. Fields,[1] Raymond C. Harris,[2] Reena Rao.[1] *[1]The Kidney Inst, Dept of Medicine, Univ of Kansas Medical Center, Kansas City, KS; [2]Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Glycogen synthase kinase-3β (GSK3β) is a serine /threonine protein kinase that plays an important role in renal tubular injury and regeneration in acute kidney injury. However its role in the development of renal fibrosis, often a long-term consequence of acute kidney injury is unknown. Using a mouse model of renal fibrosis induced by ischemia/reperfusion (I/R) injury, we demonstrate increased GSK3β expression and activity in fibrotic kidneys.

Methods: Bilateral I/R was carried out on male C57/BL6J mice**;** both renal pedicles were exposed by flank incision and clamped for 30 minutes at 37^{0}C**.** GSK3inhibitor (TDZD-8) was administered by daily IP injection at 1mg/Kg BWt. dose starting 1h before (TDZD-pre) or 48h after I/R (TDZD-post). Studies were also carried out in rat fibroblast NRK-49F cells.

Results: GSK3β expression and activity increased significantly starting 48h after I/R and remained high in the fibrotic kidneys 12 days after I/R. GSK3β was detected in renal myofibroblasts and tubules. GSK3 inhibition suppressed fibrosis, with significantly reduced myofibroblast population, extracellular matrix deposition, inflammatory mediators and TGF-β signaling in TDZD-pre and TDZD-post treatment groups compared to vehicle treated group. *In vitro,* TGF-β1 treatment increased GSK3β expression in NRK-49F cells and GSK3 inhibition abolished TGF-β1 induced SMAD-3 activation and α-SMA expression. Importantly, overexpression of constitutively active GSK3β stimulated α-SMA expression

even in the absence of TGF-β1 treatment. These results suggest that TGF-β regulates GSK3β expression, which in turn is important for TGF-β/ SMAD-3 signaling and fibroblast-to-myofibroblast differentiation.

Conclusions: The study thus demonstrates that GSK3 could promote renal fibrosis by activation of TGF-β signaling and the use of GSK3 inhibitors might represent a novel therapeutic approach for progressive renal fibrosis that develops as a consequence of AKI.

Regulating Cx43 and TRPC6 Expression Protects Renal Epithelial Damage in a Rat AKI Model Zilong Li, Wei Wang, Juan Wang, Lining Wang. *Dept of Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.*

Background: Intracellular Ca^{2+} homeostasis plays an essential role in maintaining normal cell function. Connexin43 (Cx43) and transient receptor potential channel (TRPC6) has been reported to regulate Ca^{2+} entry in some pathologic conditions. The aim of this study was to elucidate whether the modifier protein of glyceraldehyde-3-phosphate dehydrogenase (MP) and ATP-$MgCl_2$ could regulate Cx43 and TRPC6 in a rat model of acute kidney injury (AKI).

Methods: Male Sprague-Dawley rats were divided into the following groups: normal control, gentamicin-treated, MP plus gentamicin-treated, ATP-$MgCl_2$ plus gentamicin-treated (n=15 for each), as well as control group for MP and ATP-$MgCl_2$ alone (n=5 for each). Levels of serum creatine (sCr) for each group were measured on the 14th days of treatment. The "in vivo cryotechnique" was used for preparing kidney specimen as before. Immunohistochemistry staining for Cx43 and TRPC6 was performed.

Results: The gentamicin-treated group showed a significant increase in sCr compared to the normal control group. Co-treatment of gentamicin with MP and/or ATP-$MgCl_2$ produced marked decreases preventing the increase of sCr. Under light microscope, the gentamicin-treated group showed tubular epithelium damage indicating AKI. This was attenuated by MP and/or ATP-$MgCl_2$ co-treatment. Immunohistochemistry staining indicated that MP and/or ATP-$MgCl_2$ co-treatment prevented gentamicin-induced down-regulation of Cx43 and TRPC6 in renal epithelium cells using the "in vivo cryotechnique". Furthermore, the expressions of Cx43 and TRPC6 in gentamicin-treated group showed much weaker intensity using conditional fixation method compared to that using "in vivo cryotechnique" suggesting there might be artificial damage during the conditional fixation procedure.

Conclusions: Using a rat model of AKI, MP and ATP-$MgCl_2$ were able to prevent the down-regulation of Cx43 and TRPC6, which might reduce Ca^{2+} entry and its downstream signaling, thus minimizing the damage in the renal epithelium cells.

FR-PO264

S-Glutathionylation of TAZ Might Contribute to Acute Kidney Injury and Repair Rajesh kumar Gandhirajan,[1] Benedikt Bernd Walla,[1] Manaswita Jain,[1] Malte P. Bartram,[1] Markus M. Rinschen,[1] Thomas Benzing,[1,2] Bernhard Schermer.[1,2] *[1]Dept II of Medicine and Center for Molecular Medicine, Univ of Cologne, Cologne, NRW, Germany; [2]Cluster of Excellence on Cellular Stress Responses in Ageing-Associated Diseases (CECAD), Univ of Cologne, Cologne, NRW, Germany.*

Background: The clinical syndrome of acute kidney injury (AKI) is one of the most important diseases in nephrology and associated with increased morbidity and mortality. Kidney displays a remarkable potential for repair even after severe acute injury. Recent studies identified the Hippo pathway as a master regulator of organ growth and proliferation and uncovered the importance of the two mammalian Hippo-signaling effector molecules YAP and TAZ as regulators of proliferation and apoptosis during kidney development. The objective of the current study is to demonstrate that TAZ undergoes redox regulation via s-glutathionylation.

Methods: Immunoprecipitation, reporter gene assay, XTT assay, cycloheximide assay.

Results: Our findings indicate that exposure to hydrogen peroxide (H2O2) increased TAZ/TEAD transcriptional activity without affecting YAP/TEAD. Consistently, TAZ/TEAD interaction was slightly enhanced upon H2O2 exposure. Furthermore, H2O2 exposure increased nuclear localization of TAZ in a stable NIH3T3/Flp-in cell line expressing TAZ-GFP. We confirmed s-glutathionylation using recombinant TAZ protein in vitro and biotinylated glutathione ester in cell culture. To identify cysteine residues undergoing s-glutathionylation we generated TAZ C>A mutants. Reporter assays revealed that TAZ C358A showed increased transactivation of TEAD, the effect on cell proliferation and migration was also enhanced in TAZ C358A mutant. Finally, cycloheximide chase assay revealed that all of the TAZ mutants exhibited increased stability following 6h incubation.

Conclusions: Our data indicate a novel mechanism how pro-proliferative TAZ activity is regulated by ROS via s-glutathionylation, which could play an important role in tissue injury and repair. Currently, we are following the hypothesis that ROS derived from constitutively active NOX4 could modulate TAZ activity in the kidneys and we are investigating the importance of s-glutathionylation of TAZ *in vivo*.

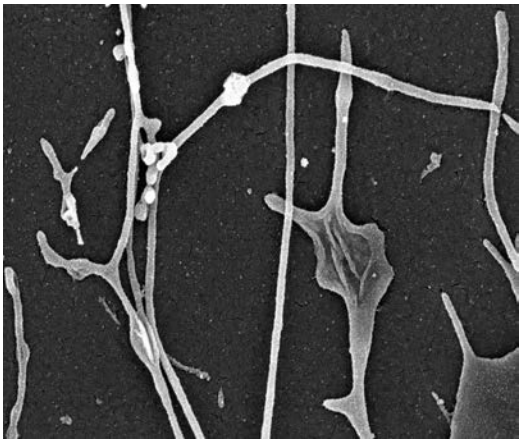
FR-PO265

Bud-Like Structure Capable of Developing to Lamellipodia in Wound Healing of Tubular Epithelium – A Scanning Electron Microscopic Approach Kiyoko Inui,[1] Hiroyuki Morita,[2] Yoshihiko Inoue,[1] Shinya Omiya,[1] Tomoaki Miyazaki,[1] Ashio Yoshimura.[1] *[1]Div. of Nephrology, Showa Univ Fujigaoka Hosp., Yokohama, Kanagawa, Japan; [2]Div. of Endocrinology and Metabolism, Aichi Medical Univ School of Medicine, Nagakute, Aichi, Japan.*

Background: Cell migration is essential in wound healing during which filamentous (F)-acin assembly plays a pivotal role. Cell biological approaches, using confocal microscopy, succeeded in identifying molecules regulating the assembly, such as the Arp2/3 complex, N-WASP, cofilin, and profilin. Although cells form filopodia (microspike) and lamellipodia (membrane), and move forward, much remains to be seen in the ultrastructure of these processes.

Methods: Rat tubular epithelium (NRK-52E) was cultured, grown to confluency, and scratched. The cells were subjected to scanning electron microscopy (SEM) at various time points. In separate experiments, immunoelectron microscopy was performed using an antibody against Arp3. Lastly, 60% confluent NRK-52E cells were cultured in the presence or absence of si-RNA for Arp3, grown to confluency, and scratched. The cells were observed periodically at the SEM levels, and, the length of time for complete recovery was compared.

Results: As shown in the figure, SEM elucidated elaborated network of filopodia containing "bud-like structure" (bud) that may develope to lamellipodia. Arp3 was expressed in filopodia and lamellipodia but not in a bud. The Si-RNA knockdown significantly prolong the length of time for the recovery. It at least partially inhibited the formation of filopodia network and lamellipodia but not the formation of a bud.



Conclusions: This is the first SEM analysis of scratch wound healing in cultured tubular epithelium, and that the bud was previously undescribed. Although the Arp2/3 complex does not apparently induce lamellipodia formation of a bud, further molecular analysis may shed a new light into cell motility in wound healing.

FR-PO266

Inhibition of Microtubule Dynamics Delays Kidney Recovery After Ischemia/Reperfusion Injury in Mice Sang Jun Han,[1] Jee in Kim,[2] Kwon Moo Park.[1] *[1]Dept of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea.*

Background: Ischemia/reperfusion (I/R) is a major cause of acute kidney injury (AKI). If recovery from AKI is delayed, kidney progresses toward chronic renal failure. Microtubules, a component of the cytoskeleton, contribute to cell damages, cell shape, cell motility, and cell division. Here, we investigate that the role of microtubule network on the kidney injury, recovery and progression of fibrosis after I/R injury.

Methods: Mice were subjected to 30 minutes of bilateral renal ischemia, and mice were sacrificed 16 days after ischemia. Some mice were administered either saline (vehicle) or paclitaxel (taxol), a microtubule stabilization agent; 1 day before ischemia (pretreatment) or from 1 day after ischemia until sacrifice every 2 days (post-treatment).

Results: Pretreatment of taxol did not affect post-I/R renal function compared with vehicle-treated I/R group. Post-treatment of taxol delayed renal functional and histological recovery with retardation of tubular regeneration, and accelerated proliferation of interstitial cells after ischemia. Post-treatment of taxol from 24 hours after ischemia enhanced cell cycle arrest, progression of fibrosis, and macrophage infiltration into the kidney. Furthermore, post-treatment of taxol suppressed repolarization of primary cilia in tubular epithelial cells.

Conclusions: In conclusion, our results demonstrate that microtubule stabilization or inhibition of cell proliferation delays kidney tubule cell restoration after ischemic injury, whereas interstitial cell proliferation is accelerated, leading to kidney fibrosis. It suggests that regulation of microtubule dynamics is critical to repair from AKI and progression of AKI to chronic kidney disease.

Tubulin Acetylation in the Kidney Tubular Cells After Ischemia/Reperfusion Injury Jihyeon Kim, Sang Jun Han, Kwon Moo Park. *Dept of Anatomy and BK21, Kyungpook National Univ, Daegu, Korea.*

Background: Acetylation of tubulin is known to play an important role in the stabilization of microtubules. Kidney ischemia/reperfusion (I/R) is a major cause of acute renal failure. I/R causes damage to the cytoskeleton in the tubular epithelial cells.

Methods: We investigated the tubulin acetylation in kidney tubular epithelial cells after I/R injury using western blotting and immunohistochemical staining. Mice were subjected to either 30 min of ischemia or sham-operation. Kidneys were harvested at various times after ischemia.

Results: Acetylated-α-tubulin expression dramatically decreased 24 hours after ischemia and then gradually increased over time. However, total α-tubulin expression was not significantly changed after I/R. In normal kidney, immune-reactivities of kidney epithelial cell to acetylated α-tubulin antibody were different in tubules; the orders were the collecting duct, the distal tubules and the proximal tubule. Twenty-four hours after ischemia, acetylated α-tubulin expression increased in the proximal tubule and the distal tubule with strong expression in the nuclei of the tubular cells. In the glomerulus, acetylated α-tubulin was also observed and the expression was very strong in the podocyte and Bowman's capsule. Twenty-four hours after ischemia, acetylated α-tubulin expression in the podocyte was lower than that of normal cells. Nine days after ischemia, acetylated α-tubulin expression in the podocyte and interstitial cell increased. Expression of α-tubulin acetyltransferase-1 (αTAT1), an enzyme involved in acetylation of α-tubulin, continuously decreased after ischemia. Histone deacetylase 6 (HDAC6), an enzyme involved in deacetylation of tubulin, also significantly decreased after ischemia.

Conclusions: Ischemia/reperfusion reduced tubulin acetylation in renal tubular cells, suggesting that I/R-induced decrease of tubulin acetylation is associated with reduction of stability of microtubule in cells.

Hypertension Aggravates Acute Kidney Injury (AKI) and Accelerates Progression to Chronic Kidney Disease (CKD) in CD1 Mice Robert Greite,[1] Anja Thorenz,[1] Faikah Gueler,[1] Katja Hueper,[2] Song Rong,[3] Hermann G. Haller,[1] Jan H. Braesen.[4] *[1]Nephrology, Hannover Medical School, Hannover, Germany; [2]Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany; [3]Central Animal Facility, Hannover Medical School, Hannover, Germany; [4]Pathology, Hannover Medical School, Hannover, Germany.*

Background: AKI can be complicated by hypertension due to activation of the RAAS system. However, the most frequently used laboratory mouse strain (C57Bl/6) lacks blood pressure elevation after renal injury. In this study we provide evidence that hypertension aggravates post-ischemic AKI and accelerates progression to chronic kidney disease (CKD) in CD1 mice.

Methods: IRI was induced by transient clamping of the renal pedicles for 35 minutes in CD1 compared to C57Bl/6 mice. Survival, renal function (creatinine, BUN), glomerular filtration rate (GFR) and renal blood flow (RBF) were measured by inulin/PAH-clearance and renal perfusion impairment was assessed by functional magnetic resonance imaging (MRI). Systemic blood pressure was measured by a tail cuff method at different time points after IRI. Morphological changes were investigated by Masson Goldner staining and immunohistochemistry for inflammation (myeloid cell infiltration) and fibrosis (collagen and fibronectin expression). In addition, silver stain was done to quantify mesangial matrix expansion.

Results: Renal function impairment after IRI was similar in CD1 and C57Bl/6 mice but only the CD1 mice developed severe blood pressure elevation (+20 mmHg) within 2 weeks. Functional MRI revealed long lasting impairment of renal perfusion in CD1 mice and markedly better recovery in C57Bl/6 mice. Similar results were obtained by PAH clearance measurements. Histologically, AKI score and inflammation was similar at day 1 after IRI in both mouth strains. Within 14 days after IRI CD1 mice developed severe tubulo interstitial fibrosis. In contrast, C57Bl/6 recovered and had only mild focal cortical scaring after 14 days. Silver stain revealed significant mesangial matrix expansion only in CD1 mice correlating with accelerated glomerulosclerosis.

Conclusions: CD1 mice show severe blood pressure elevation in ischemia induced AKI which accelerates the progression to CKD.

Pericyte MyD88 Controls Inflammatory and Fibrotic Responses to Kidney Injury Irina Alexandra Leaf,[1] Ivan G. Gomez,[1] Bryce Gordon Johnson,[1] William A. Altemeier,[2] Jeremy Stuart Duffield.[1] *[1]Research & Development, Biogen, Cambridge, MA; [2]Medicine, Univ of Washington, Seattle, WA.*

Background: Sterile inflammation is increasingly recognized as a central problem in many acute and chronic diseases but the mechanisms controlling responses to sterile inflammation are poorly understood. Injured or dying cells release products, or Danger Associated Molecular Patterns (DAMPs), recognized by immune receptors contributing to disease progression. Here we show that DAMPs isolated from injured kidney activate TLR2/4 and MyD88 dependent transcription of immune genes in non-immune kidney resident cells, pericytes. When treated with extracellular DAMPs pericytes form an active NLRP3 inflammasome, process pro-IL1 and pro-IL18 to their active secreted forms and undergo pyroptosis, thereby contributing to inflammation and leukocyte trafficking.

Results: Recent studies have indicated that kidney pericytes represent a major source of interstitial myofibroblasts in renal fibrogenesis. We show that treatment with DAMPs *in vitro* activate pericyte to myofibroblast transition indicated by upregulation of transcription of fibrotic genes *Col1a1* and *Acta2* and production of SMA. MyD88$^{-/-}$ pericytes showed significant reduction in fibrogenesis markers. In wound healing assays DAMPs caused pericyte migration, which was significantly reduced in the absence of MyD88. Cell-specific ablation of MyD88 in perivascular and stromal cells in models of ischemic acute kidney injury in mice significantly attenuates innate immune activation, injury and fibrogenic responses. In addition, we show that human pericytes respond to DAMPs in a similar manner by activating immune genes, secreting pro-inflammatory cytokines and inducing pyroptotic cell death.

Conclusions: In conclusion, pericytes respond to sterile inflammation via two divergent mechanisms both of which are controlled by MyD88: activation of immune signaling which enables detection and amplification of the inflammatory signal; and activation of fibrogenesis contributing to pathology. Therefore, this regulation could be an important new therapeutic target for tissue injury.

Gadd45-Gamma Protects against Acute Kidney Injury Gyu Tae Shin, Inwhee Park, Heungsoo Kim. *Dept of Nephrology, Ajou Univ School of Medicine, Suwon, Kyunggi, Korea.*

Background: Growth arrest and DNA-damage-inducible protein-gamma (Gadd45-gamma) is a protein which plays a role in the G2/M cell cycle checkpoint. We previously suggested that Gadd45-gamma may be involved in chronic kidney damage. In the present study, we investigated the function of Gadd45-gamma in acute septic and toxic kidney injury.

Methods: Acute kidney injury (AKI) was induced *in vivo* by intraperitoneal injection of lipopolysaccharide (LPS, 10mg/kg) and cisplatin (20mg/kg) in wild-type (WT) and Gadd45-gamma KO mice. Proteome array kits were used to detect differentially regulated proteins in serum (40 pro-inflammatory proteins) and kidney cortex (111 proteins). Stable Gadd45-gamma knockdown cell lines were established in primary human renal epithelial (HRE) cells using shRNA expression vectors. Gadd45-gamma was over-expressed using the recombinant adenovirus harboring the Gadd45-gamma open reading frame. Differentially regulated genes in cisplatin treated HRE cells were determined using the microarray analysis.

Results: Gadd45-gamma was significantly induced as early as 2 h after LPS injection in the kidney of WT mice. At 24 h after LPS injection, both WT and KO mice showed AKI evidenced by high urinary NGAL and elevated serum creatinine levels, where KO mice showed significantly higher serum creatinine levels with lower creatinine clearance than WT mice. Pro-inflammatory cytokines in serum were not different, however, the expression of several chemokines in kidneys were significantly higher in KO mice. In contrast, the expression of pro-fibrotic cytokines was significantly lower in KO mice. At 48 h after cisplatin injection, only KO mice showed significantly elevated serum creatinine levels with heightened NGAL expression. In cisplatin treated HRE cells, pro-inflammatory cytokines were significantly up-regulated by Gadd45-gamma knockdown, and down-regulated by Gadd45-gamma overexpression, whereas pro-fibrotic cytokines were significantly down-regulated by Gadd45-gamma knockdown.

Conclusions: The up-regulation of Gadd45-gamma protects against acute kidney injury, however, maladaptively increases the expression of pro-fibrotic molecules.

FR-PO271

Pyridorin® Reduces Renal Injury and Post Injury Fibrosis After Ischemia Reperfusion Induced Acute Kidney Injury Nataliya Skrypnyk,[1] Paul A. Voziyan,[1] Haichun Yang,[1] Carrie Turich Taylor,[2] Raymond C. Harris,[1] Billy G. Hudson,[1] Mark P. de Caestecker.[1] *[1]Div of Nephrology, Vanderbilt Univ, Nashville, TN; [2]NephroGenex, Inc., Raleigh, NC.*

Background: Pyridorin (PYR), an inhibitor of pathogenic oxidative chemistries, has a favorable safety profile in clinical trials and has been shown to scavenge reactive oxygen species (ROS) and reactive carbonyl species (RCS) *in vitro* and *in vivo* animal studies. ROS and RCS are highly up regulated during kidney injury. In this study we propose that PYR treatment will reduce injury and ameliorate long-term fibrosis after ischemia-reperfusion acute kidney injury (IR-AKI).

Methods: Ischemia-reperfusion mouse models: 1) unilateral ischemia reperfusion (UIR) (31min), injury evaluation on day 3 after injury (UIR D3); and 2) UIR with delayed contralateral nephrectomy (DCN) on day 9, fibrosis and injury evaluation on day 28 (UIR DCN D28).

Results: Preventive treatment with PYR at 500 mg/kg/day (PYR500) and 1000 mg/kg/day (PYR1000) via drinking water in the UIR D3 model demonstrated dose dependent reduction in mRNA levels of kidney injury markers Kim1 and NGAL, tubular injury score, and an oxidative stress marker, isofuran-to-isoprostane ratio. Plasma PYR levels were proportional to PYR dose. There was a dose dependent reduction in fibrosis after PYR pre-treatment in the UIR DCN D28 model. PYR1000 reduced mRNA levels of Col1a1, Col3a1 and aSMA. PYR pre-treatment was more effective at inhibiting expression of these pro-fibrotic markers compared with post-injury treatment, which only reduced expression of aSMA mRNA in the UIR DCN D28 model.

Conclusions: PYR pre-treatment ameliorates I/R-AKI in dose dependent manner. Pre-treatment with PYR is more effective than post injury treatment and can inhibit progression to chronic kidney disease. These studies suggest PYR as a prospective drug for treatment of patients at risk of AKI. Funded by research grant from NephroGenex, Inc.

Canonical BMP Signaling via BMPR1A and Smad1/5/8 Mediates the Transition to Fibrosis After Renal Ischemia Reperfusion Injury Emilia Vigolo,[1] Lajos Marko,[2] Christian Hinze,[1] Dominik N. Müller,[1,2] Ruth Schmidt-ullrich,[1] Kai M. Schmidt-Ott.[1,2,3] *[1]Max Delbrueck Center for Molecular Medicine, Berlin, Germany; [2]Experimental and Clinical Research Center, Charitè, Berlin, Germany; [3]Dept of Nephrology, Charitè - Universitaetsmedizin, Berlin, Germany.*

Background: Ischemia reperfusion injury (IRI) of the kidney leads to acute kidney injury (AKI) and frequently precipitates the development of tubulointerstitial fibrosis. Bone morphogenic protein (BMP) signaling has been implicated in the pathogenesis and progression of the disease, but its tubular-specific role is unclear.

Methods: We induced IRI in mice by clamping the left renal pedicle for 25 minutes. The severity of the damage was confirmed by histology scoring, elevated mRNA expression of renal injury markers NGAL and KIM-1 and increased urinary NGAL (uNGAL) excretion 24h post-ischemia. Activation of canonical BMP signaling was detected by nuclear pSmad1/5/8 immunostaining and Western blotting. To achieve a doxycycline-dependent Cre-mediated inactivation of BMP receptor 1a (Bmpr1a) in renal tubules, we generated *Pax8rtTa;LC1;Bmpr1a* $^{fl/fl}$ mice (Bmpr1a cKO).

Results: Canonical BMP activity, as revealed by pSmad1/5/8, was widely detected in healthy wild-type (wt) mouse kidney tubules. IRI caused a sustained injury in wt kidneys as shown by elevated NGAL and KIM-1 expression and increased uNGAL excretion. In parallel, we observed a transient decrease of pSmad1/5/8 with minimal activity at 48 hours and a subsequent re-activation at 7 days post-ischemia. Bmpr1a cKO mice displayed normal renal tissue morphology and renal functions at baseline. Following IRI, Bmpr1a cKO mice exhibited an initial injury similar to controls, but at 7 days post-ischemia, the expression of collagen IV and TGF-β1 were significantly up-regulated in Bmpr1a cKO kidneys compared to controls. Unlike controls, Bmpr1a cKO mice failed to reactivate tubular pSmad1/5/8 activity at 7 days after injury. 21 days following IRI, Bmpr1a cKO kidneys displayed an increased percentage of tubulointerstitial fibrosis compared to controls.

Conclusions: Tubular Bmpr1a-dependent Smad1/5/8 signaling is transiently decreased after renal IRI and its reactivation limits the progression of tubulointerstitial fibrosis.

FR-PO273

PNUTS (Phosphatase 1 Nuclear-Targeting Subunit) Is Down-Regulated in Acute Kidney Injury and by Aging, and Regulates Cell Cycle, Fibrosis, DNA Damage of Renal Tubular Cells Yuki Osakabe, Tatsuki Matsumoto, Kazu Hamada-Ode, Yoshiko Shimamura, Koji Ogata, Kosuke Inoue, Yoshinori Taniguchi, Taro Horino, Shimpei Fujimoto, Yoshio Terada. *Kochi Univ, Japan.*

Background: PNUTS (phosphatase 1 nuclear-targeting subunit, also known as PPP1R10) has recently reported to be regulated in cardiac aging and play roles in DNA damage. Aging and fibrosis play crucial roles in AKI to CKD transition, however the precise mechanism are not known. Because the biological role of PNUTS in aged kidney, fibrosis, and cell cycle in AKI is poorly understood, we studied the regulation and the functional roles of PNUTS in AKI and aging.

Methods: We used an in vivo mice aristolochic acid(AA)-induced AKI model and cultured renal tubular cells (NRK-52E cells). To assess aging effects, we evaluated PNUTS expression, renal function, and renal fibrosis in AA-induced AKI model in different aged mice (20-, 50- and 90-week-old). To elucidate the function of PNUTS, cell cycle regulation (by FACS), DNA damage (by gammaH2AX expression), and fibrosis (by CTGF expression) were examined in NRK-52E cells transfected with siRNA for PNUTS or PNUTS expression vector.

Results: In mice with AA-induced AKI, protein and mRNA expression of PNUTS were reduced compared with control mice. Moreover, PNUTS expression were decreased in accordance to aging. Reduction of renal function and renal fibrosis were more apparent in aged AKI mice. Immunohistological examination revealed the reduced expression of PNUTS in the proximal tubular cells in AA-induced AKI. PNUTS mRNA and protein expression showed a dose-dependent reduction by H_2O_2 in NRK-52E cells. Overexpression of PNUTS reduced H_2O_2-induced caspase3 activity and apoptotic (TUNEL positive) cell number. Transfection of siPNUTS significantly increased G2/M phase cells, CTGF expression, and DNA damage.

Conclusions: These results indicate that PNUTS expression was reduced in AA-induced AKI and in aged mice. Expression of PNUTS was partially regulated by oxidative stress. PNUTS regulates cell cycle, CTGF expression, DNA damage, and apoptosis in NRK-52E cells. These results suggest that regulation of PNUTS may play a key role in the pathophysiology of AKI and age-related renal damage.

FR-PO274

Class Ia HDAC Inhibitors Restore BMP-7 Expression and Inhibit the Pathogenesis of Renal Fibrosis following Chronic Renal Injury Qiusha Guo, Scott R. Manson, Katelynn H. Moore, Paul F. Austin. *Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.*

Background: BMP-7 is a potent anti-fibrotic cytokine that is also required for the repair of renal injuries. However, chronic renal injury leads to the loss of BMP-7 and fibrosis. Here, we delineate the molecular mechanisms that lead to the loss of BMP-7 expression and examine potential therapeutic strategies for stimulating the innate repair mechanisms of the kidney.

Methods: BMP-7 expression was studied *in vitro* in inner medullary collecting duct (IMCD) cells and *in vivo* in a murine model of unilateral ureteral obstruction (UUO). The therapeutic effects of broad spectrum histone deacetylase (HDAC) inhibition with Trichostatin A (TSA) and Class Ia HDAC inhibition with MS-275 were evaluated by assessing renal pathology.

Results: UUO results in an 83.1% decrease in BMP-7 mRNA expression that is paralleled by a 63.0% decrease in the acetylation of histone proteins in the proximal *Bmp7* promoter, a process that results in gene repression. These changes are HDAC-dependent and blocked by treatment with TSA. An *in vitro* pharmacologic screen in IMCD cells revealed that MS-275 stimulates BMP-7 expression, while inhibitors of other HDAC isoforms have no effects. These results were confirmed by using siRNA-mediated genetic ablation to demonstrate specificity and chromatin immunoprecipitation to show binding of the Class Ia HDAC proteins HDAC1 and HDAC2 to the *Bmp7* promoter. MS-275 also stimulates the anti-fibrotic functions of BMP-7 *in vitro* by suppressing the expression of the TGF-β-dependent pro-fibrotic genes *COLIa1* and *aSMA* by 68.2% and 97.6%, respectively. Finally, these effects extend to the obstructed kidney *in vivo* where HDAC inhibition results in a 2.7-fold increase in BMP-7 expression, 42.7% decrease in fibroblast activation, and 63.7% decrease in renal fibrosis.

Conclusions: These findings demonstrate that HDAC1 and HDAC2 are responsible for the loss of BMP-7 expression and its renal protective functions in the injured kidney. Furthermore, our study suggests that Class I HDAC inhibitors have a tremendous therapeutic potential for stimulating kidney repair and inhibiting disease progression following chronic renal injury.

FR-PO275

Gli2 in Perivascular MSC Is Required for Kidney Fibrosis and Can Be Targeted Pharmacologically Rafael Kramann, Susanne V. Fleig, Steven L. Fabian, Omar H. Maarouf, Janewit Wongboonsin, Yoichiro Ikeda, Benjamin D. Humphreys. *Renal Div, Brigham and Women´s Hospital, Boston, MA.*

Background: We recently demonstrated that perivascular mesenchymal stem cell (MSC)-like cells are defined by expression of Gli1 and are critical myofibroblast precursors. We now investigate the role of Gli transcriptional activators in myofibroblast progenitors during kidney fibrosis and value as therapeutic targets.

Methods: We utilized mouse genetics, drug binding, RNAi and retroviral overexpression to dissect the roles of Gli1 vs. Gli2 in myofibroblast activation and fibrosis. We pharmacologically targeted Gli proteins with Darinaparsin, an arsenical, and GANT61, a small molecule Gli inhibitor. We evaluated them in two separate mouse CKD models. We measured hedgehog pathway activity and expression of Gli in human kidney fibrosis specimen.

Results: In vitro knockdown of Gli1 had no appreciable effect whereas knockdown of Gli2 induced a G0/G1 cell cycle arrest of mouse fibroblasts. Conversely, Gli2 overexpression rescued this cell-cycle effect and drove proliferation. In vivo, knockout of Gli1 showed no effect on fibrosis severity after UUO whereas either conditional knockout of Gli2 or overexpression of the Gli3 repressor in $Gli1^+$ pericytes ameliorated fibrosis and induced a G0/G1 cell cycle arrest specifically in myofibroblasts, consistent with our in vitro results. We show that darinaparsin directly binds to Gli2, lowers Gli2 protein levels and induces a G0/G1 cell cycle arrest. This effect of darinaparsin absolutely requires Gli2, and Gli2 overexpression rescued the cell cycle defect. When administered in a therapeutic dosing strategy after UUO or IRI, darinaparsin potently reduced Gli1 and Gli2 expression, induced myofibroblast specific G0/G1 cell-cycle arrest and ameliorated fibrosis. GANT61, structurally unrelated to darinaparsin, showed the exact same effects. In human kidneys with fibrosis there is strong upregulation of Gli1 and Gli2 mRNA, suggesting this pathway is conserved in humans.

Conclusions: Gli2 is a critical driver of myofibroblast proliferation and a novel therapeutic target in kidney fibrosis.

Klotho Influences the Fate of Fibrosis in Cardio-Renal Protection Steven M. Weldon,[1] Hu Sheng Qian,[1] Nestor X. Barrezueta,[1] Jorge L. Villalona,[1] R. Paul Fracasso,[1] Glenn A. Reinhart,[1] Jian Xie,[2] Chou-Long Huang,[2] Noelynn Oliver.[1] *[1]CardiMetabolic Disease Research, Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; [2]Univ of Texas SW Medical Center, Dallas, TX.*

Background: Soluble Klotho is an endogenous hormone produced predominantly by extracellular domain shedding of membrane Klotho in the kidney. Although Klotho is thought to provide cardio-renal protection through its regulation of ion transport and growth factor signaling, specific cellular localization and function of Klotho in the normal and diseased kidney are not clearly defined.

Methods: We evaluated Klotho expression and localization in human and mouse kidney via in situ hybridization (ISH), immunohistochemistry (IHC) or RNAseq. Cardio-renal protective effects of soluble human Klotho administration were studied in mouse unilateral ureteral obstruction (UUO; 5 day) and isoproterenol-induced cardiac hypertrophy (ISO, 5 mg/lg/d x 10d) models.

Results: In normal adult human kidney (fresh nephrectomy and autopsy, n=9), Klotho was highly expressed in distal tubules (DT) and in both cortical and outer medulla collecting ducts (CD). Proximal tubule and podocyte expression was low but detectable. Following UUO, renal Klotho RNA was decreased 61% and protein content was reduced greatly in the distal nephron vs Sham kidney. Klotho treatment (10 ug/kg, Q2D, IP) attenuated UUO-induced tubulointerstitial fibrosis (picrosirius red stain, n=10) by 67%* (*p<.05) and

biomarker mRNA (40%*:FN1; 25%:aSMA; 16%:TGFb) vs Vehicle control. In the ISO model, Klotho (10 ug/kg QD, IP) inhibited cardiac hypertrophy (HW:BW, n=6); 5.4±.08 (p<.01) in Klotho- vs 5.8±0.08 in Vehicle control.

Conclusions: Klotho is highly expressed in normal human and mouse distal nephron. Klotho mRNA and protein are reduced in preclinical models of cardiac and renal disease. Delivery of recombinant Klotho attenuates severity of pathology and biomarker expression in the UUO model of renal fibrosis and ISO-induced cardiac hypertrophy. Klotho pharmacotherapy has the potential to prevent CKD progression as well as the progression of extra-renal Klotho-dependent diseases.

Kidney Interstitial Cell Derived Tenascin C Plays an Important Role in Promoting Injury-Repairing of the Kidney by Stimulating Cell Proliferation Min Zhang, Qionghong Xie, Xiaoyi Mao, Da Shang, Chuanming Hao. *Div of Nephrology, Huashan Hospital, Shanghai, China.*

Background: Tenascin-C (TNC) is a glycoprotein expressed in extracellular matrix during development and injury repairing. This study explored the role of TNC in acute kidney injury (AKI).

Methods: A TNC promoter driven inducible CreER2 knock-in mouse line with EGFP reporter (IRES-EGFP) as generated (TNC-CreER-eGFP). AKI was induced by 40 minutes of ischemia followed by reperfusion in unilateral nephrectomized mice (UN+UIR). Cell lineage tracing was conducted in TNC-CreER;R26-tdTomato mice to examine the origin of TNC expressing cells. The effect of TNC on cell proliferation was examined using a cell count kit in cultured HK2 cells. TNC expression was also examined in human biopsies with IRB approval.

Results: In normal kidney, TNC was restricted in renal papilla in both mice and human. Following IR, TNC was markedly induced in renal cortex, particularly in injured areas. TNC reporter showed that induced TNC expression is localized in interstitial cells, but not tubular epithelial cells. TNC induction was also shown in human renal biopsies with AKI. Co-staining IF showed that TNC was expressed by the PDGFRβ(+) renal interstitial cells, but not NG2(+) pericyte, F4/80(+) macrophage and FSP-1(+) cells. Lineage tracing revealed that TNC expressing cells following IR were not derived from the renal medullary interstitial cells that constitutive express TNC, suggesting new TNC induction. To examine the role of TNC induction following AKI, $TNC^{-/-}$ mice were generated. TNC deletion significantly increased mortality (0% vs 50% on day 7, n=14, P=0.002), with significantly higher BUN levels (108 vs 22 mmol/L on day 2, P<0.05) compared with wide type mice. More severe kidney damage in TNC knockouts was also supported by histology study. To examine the mechanism by which TNC protected the kidney from injury, HK2 cells were cultured. Exogenous TNC significantly increased cell proliferation by 50%.

Conclusions: TNC is induced in renal interstitial cells after IR-induced AKI, protecting the kidney from injury. The protective effect of TNC on AKI may be associated with promoting renal recovery by stimulating epithelial cell proliferation.

TAZ and YAP Are Mechanoregulators of TGF-β-Smad Signaling and Renal Fibrogenesis Darren A. Yuen, Stephen G. Szeto, Masahiro Narimatsu, Ahmad Mohammad Omar Sidiqi, Mingliang Lu, Jeffrey Wrana, Andras Kapus. *Univ of Toronto, Canada.*

Background: Fibrosis is a final common injury pathway responsible for the progression of most forms of CKD, for which no specific treatments exist. Driven largely by TGF-β signalling, fibroblast-myofibroblast transition is crucial for fibrogenesis. While it is known that fibroblast activation is mechanosensitive, with soft matrix akin to a healthy kidney impairing TGF-β responsiveness, the underlying mechanisms remain poorly understood. TAZ and YAP are homologous transcription co-factors with TGF-β regulatory activity, whose nuclear localization and activity are regulated by matrix stiffness. Here, our aim was to examine how stiffness regulates TGF-β signalling via TAZ/YAP, and to test if TAZ/YAP inhibition can attenuate renal fibrosis.

Methods: The effects of matrix stiffness on TAZ/YAP localization and TGF-β/Smad signalling were examined in rat renal fibroblasts (NRK49Fs) cultured on soft (2 kPa) and stiff (100 kPa) gels. To test the effect of TAZ/YAP inhibition, NRK49F cells and mice were treated with verteporfin (VP), a drug used as a macular degeneration treatment with recently described TAZ/YAP inhibitory properties.

Results: In NRK49F cells, stiff matrix resulted in nuclear TAZ/YAP localization and enhanced TGF-β signalling. Growth on soft matrix, in contrast, lead to reduced TAZ/YAP nuclear localization, and impaired TGF-β-induced Smad2/3 nuclear accumulation and transcriptional activity. VP treatment of NRK49F cells grown on stiff plastic surfaces resulted in a dramatic loss of TAZ/YAP, leading to a similar inhibition of TGF-β/Smad signalling. VP-induced TAZ/YAP loss also enhanced proteasomal Smad2/3 degradation following TGF-β stimulation. *In vivo*, VP similarly reduced renal TAZ/YAP and Smad2/3 levels in UUO mice, leading to diminished myofibroblast accumulation and interstitial collagen deposition.

Conclusions: Our data suggest that renal fibrogenesis is regulated by a novel mechanical stimulus (stiffness) that, through control of the mechanosensory proteins TAZ and YAP, modulates TGF-β/Smad signalling. Furthermore, we identify verteporfin as a potential anti-fibrotic treatment that interferes with this pro-fibrotic mechano-chemical synergy.

Targeted Deletion of Numb from Proximal Tubules Attenuates Interstitial Fibrosis by Mitigating G2/M Arrest Fengxin Zhu, Jing Nie. *Div of Nephrology, Nanfang Hospital, Guangzhou, Guangdong, China.*

Background: Progressive tubulointerstitial fibrosis (TIF) is the final common pathway leading to end stage renal disease. Tubular epithelial cells (TECs) have a crucial role in the pathogenesis of TIF. Numb is a multifunctional protein involved in diverse cellular processes. However, little is known about the physiologic and pathologic role of Numb in kidney.

Methods: We examined the expression and distribution of Numb in normal adult mouse kidney as well as in mouse model of renal fibrosis induced by unilateral ureteral obstruction (UUO). To explore Numb's role in renal fibrosis, we generated a conditional knockout mouse model in which Numb is selectively ablated from proximal tubules (PEPCK-Numb-KO). To confirm the role of Numb in regulating cell cycle, Numb was overexpressed in NRK52E cells by infecting with a Numb adenovirus (Ad-Numb) and endogenous Numb was knocked down by siRNA in HK-2 cells before aristolochic acid (AA) treatment. To examine the role of p53 in Numb-induced G2/M arrest, Ad-Numb infected HK-2 cells were incubated with pifithrin-α, a p53 inhibitor.

Results: Numb is expressed in renal tubules and glomeruli. The expression of Numb in renal tubules was significantly increased after UUO. After UUO, PEPCK-Numb-KO mice exhibited significantly attenuated TIF. Ectopic expression of Numb increased the fraction of cells in G2/M stage and upregulated the expression of TGF-β1 and CTGF in NRK52E cells. Knocking down endogenous Numb attenuated AA-induced G2/M arrest and profibrotic cytokines production. Furthermore, G2/M arrest and expression of profibrotic cytokines were significantly reduced in PEPCK-Numb-KO mice after UUO. Inhibiting p53 activity dramatically mitigated Numb-induced G2/M arrest and profibrotic cytokines production.

Conclusions: In summary, our studies demonstrate that Numb has a profound effect on promoting G2/M arrest of TECs through stabilizing p53 protein. Depletion of Numb markedly attenuates G2/M arrest of proximal tubules which in turn reduces TIF. Collectively, these data indicate that targeting Numb might be a novel therapeutic approach for the treatment of fibrotic kidney diseases.

FR-PO280

Identification of a New Aldosterone Synthase Inhibitor with Anti-Fibrotic Activity in Animal Models Bert Oehlen, Siobhan McCormack, Ping Zhou, Liming Zhang, Xingxi Peng, Jingsong Li, Xiaokang Zhu, Bijoy Panicker, Itzhak D. Goldberg. *Angion Biomedica Corp., Uniondale, NY.*

Background: The renin-angiotensin-aldosterone system (RAAS) plays a critical role in renal physiology. Inhibitors of ACE and ARBs are currently the mainstay in the clinical management of chronic kidney disease (CKD). Despite initial success in reducing aldosterone, concentrations return to pretreatment levels in 30-40% of patients. This "aldosterone escape" significantly limits the therapeutic effectiveness. Through mineralocorticoid receptor dependent and independent processes, aldosterone is thought to directly accelerate renal damage by sustaining inflammation and fibrosis. An attractive approach to deal with aldosterone escape is to inhibit aldosterone synthase (AS), the enzyme responsible for aldosterone production (encoded by the CYP11B2 gene).

Methods: We have identified a promising series of potent and selective small molecule inhibitors of AS. Lead compound ANG3586 has 7 nM potency against AS and excellent selectivity against other P450 enzymes. It is orally bioavailable in rodents and appears to be well tolerated. ANG3586 was tested in the rat remnant kidney model (25 mg/kg, po, bid) and the mouse unilateral ureteral obstruction (UUO) model (25 mg/kg, po, bid, ten days).

Results: In the rat remnant kidney model, animals with overt renal dysfunction were treated with vehicle or ANG3586. The elevated blood pressure in 5/6 nephrectomized animals was reduced to normal by compound treatment. ANG3586 also markedly reduced kidney collagen content and improved renal histology. Renal function, as determined by serum BUN and creatinine levels, urine albumin to creatinine ratio and urine NGAL, was found to be markedly improved. In the mouse UUO model, ANG3586 reduced the increase in kidney weight, kidney collagen and alpha-smooth muscle actin staining. Since UUO does not result in distinctly increased blood pressure, the anti-fibrotic activity appears independent of blood pressure lowering activity of ANG3586.

Conclusions: Taken together, ANG3586 shows promise as a potential novel anti-fibrotic agent.

FR-PO281

Tubulointerstitial Fibrosis Increases Peritubular Capillary Permeability and Induces Subsequent Hypoxia Jun Zou,[1,2] Jae Won Yang,[1] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Dept of Pathology, Microbiology, and Immunology, Vanderbilt Univ, Nashville, TN; [2]Div of Nephrology, XinHua Hospital, Shanghai Jiao Tong Univ, Shanghai, China.*

Background: We previously showed that folic acid-induced tubulointerstitial injury sensitizes to subsequent glomerular injury. In this study, we evaluated whether the function of peritubular capillaries and oxygen supply changes contribute to this cross-talk of tubular to glomerular injury.

Methods: Col I-luciferase mice, which have luciferase inserted in the collagen I promoter, were mated with Nep25 mice, which express human CD25 receptor on podocytes, and develop glomerulosclerosis when immunotoxin is administered. Mice were treated with folic acid (FA, 240mg/kg BW, i.p.) or vehicle (VEH). At day 42,

mice were sacrificed to assess interstitial fibrosis, peritubular capillary number (CD31 immunostaining), endothelial function (in vivo injection of Evans blue dye), and tissue hypoxia (hypoxyprobe, pimonidazole).

Results: Folic acid induced acute tubular injury over two weeks, evidenced by increased urinary NGAL and Kim-1 levels. Six weeks later, tubular epithelial cells had regenerated and urinary NGAL and Kim-1 returned to baseline level. However, bioluminescence imaging, an indicator of collagen I mRNA transcription, showed higher density in folic acid vs vehicle (FA $31.6\pm5.1\times10^4$ *vs.* VEH $3.2\pm0.6\times10^4$ p/sec/cm2/sr, $P<0.05$). Interstitial fibrosis and collagen I were increased in FA compared to VEH (picrosirius red area, FA 14.5±1.6 *vs.* VEH 7.4±0.7%, $P<0.05$; collagen I IHC, FA 16.7±1.2 *vs.* VEH 10.6±1.3%, $P<0.05$), with a patchy distribution. Folic acid did not reduce peritubular capillary density (FA 5.5±0.7 *vs.* VEH 6.0±0.8%, pNS). However, peritubular capillary permeability, measured by extravasated Evans blue dye in the kidney, significantly increased in folic acid-treated group (FA 50.4±5.3 *vs.* VEH 28.6±3.2mg/g, $P<0.05$). Pimonidazole staining intensity was increased,suggesting tubulointerstitial hypoxia.

Conclusions: We conclude that tubulointerstitial fibrosis may lead to increased peritubular capillary permeability and subsequent hypoxia, which may contribute to crosstalk of interstitial fibrosis promoting glomerular injury.

Homocysteine Induces Collagen I Expression by Downregulating Histone Methyltransferase G9a Wenjing Lei, Jing Nie. *State Key Laboratory of Organ Failure Research, National Clinical Research Center of Kidney Disease, Div of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, China.*

Background: Hyperhomocysteinemia (HHcy) leads to several clinical manifestations including renal fibrosis. Excess deposition of extracellular matrix (ECM) components including collagen is the eponymous lesion of renal fibrosis.

Methods: Wild-type C57BL/6 mice, at the age of 6-9 weeks, were fed with either standard rodent chow or HM diet . After 2 weeks on the diet, mice were sacrificed. Kidney tissues were removed. HK-2 cells were cultured in DMEM containing DL-Hcy. The expression of G9a and Collagen I were examined by Western blot and qPCR. Renal pathological changes were assessed in tissue sections stained with Collagen I and Masson staining. HK-2 cells were transfected with pCol-GL3 reporter plasmid, pRL null together with siG9a or Flag-tagged G9a to examine the promoter activity of *COL1A1*. The level on G9a and H3K9me2 on the promoter of *COL1A1* was assessed by CHIP assay.

Results: we demonstrated that elevated concentration of Hcy induced the expression of collagen type I in cultured HK-2 cells as well as in kidney tissue of HHcy mice. Meanwhile, Hcy inhibited the expression of histone methyltransferase G9a. Mechanistically, silencing endogenous G9a by siRNA enhanced the promoter activity of *COL1A1* in HK-2 cells. Conversely, overexpressing G9a inhibited the promoter activity of *COL1A1*. CHIP assay demonstrated that G9a binds to the neuron-restrictive silencer element (NRSE) on the promoter of *COL1A1*. Hcy treatment decreased the binding of G9a on NRSE, which in turn decreased the level of H3K9me2 on the promoter of *COL1A1*, led to upregulation of *COL1A1*.

Conclusions: These results show that homocysteine induces collagen I expression by downregulating histone methyltransferase G9a and provide a novel mechanism on explaining how HHcy promotes ECM production.

The Podocyte Adhesome Exhibits Matrix Ligand Specificity with Implications for Glomerular Disease Michael J. Randles,[1,2] Roy Zent,[3] Martin J. Humphries,[1] Rachel Lennon.[1,2] *[1]Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, Univ of Manchester, Manchester, United Kingdom; [2]Inst of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester, Manchester, United Kingdom; [3]Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: Adhesion at both thepodocyte slit diaphragm and podocyte-extracellular matrix (ECM) interface is essential glomerular filtration barrier integrity. These structures converge onto many of the same signalling pathways, including those controlling the actin cytoskeleton. Podocytes adhere to laminin-521 in the glomerular basement membrane via integrin α3β1 and evidence suggests that attachment to collagen IV is upregulated in disease states. Whether changes in ECM ligand alter podocyte adhesion signalling remains unclear.

Methods: We analysed podocyte morphology following engagement of either laminin-521 or type IV collagen (α1α1α2) and isolated basolateral adhesion complexes for analysis by mass spectrometry (MS). To isolate nephrin-nephrin complexes for analysis by MS we generated nephrin-FLAG podocyte and recombinant nephrin.

Results: Human podocytes cultured on type IV collagen spread rapidly in an unpolarised manner forming radial actin stress fibres. By comparison, elongated cells with multiple lamellipodia and filopodia-like projections were formed on laminin 521. These cell phenotypes were enhanced with overexpression of the key slit diaphragm protein nephrin. The composition of isolated adhesion complexes was determined by ECM ligand and nephrin expression status. MS and protein interaction network mapping highlighted PKCα as a key signalling node in laminin adhesion complexes. Analysis of nephrin-nephrin complexes highlighted significant overlap with ECM adhesion signalling suggesting crosstalk mechanisms.

Conclusions: In human podocytes we discovered that both ECM ligand and overexpression of nephrin influences morphology, adhesion complex composition and intracellular signalling. Enhanced understanding about the pathways that control podocyte adhesion may ultimately inform therapeutic strategies to correct or repair glomerular barrier function.

Low-Density Lipoprotein Receptor-Related Protein 5 Drives Tubulointerstitial Fibrosis via Regulation of TGF-β Signaling Xuemin He, Rui Cheng, Jian-xing Ma. *Dept of Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: Low-density lipoprotein receptor-related protein 5 (LRP5), a co-receptor of the canonical Wnt/β-catenin pathway, was recently reported to drive idiopathic pulmonary fibrosis through activating β-catenin. In this study, we examined the potential role of LRP5 in the regulation of TGF-β signaling in tubulointerstitial fibrosis.

Methods: LRP5-deficient (*Lrp5*$^{-/-}$) mice and age-matched wild-type (WT) mice were subjected to unilateral ureteral obstruction (UUO). Renal expressionfibrotic factors, including α-SMA, CTGF, collagens and fibronectin, was quantified by picro-sirius red staining, western blot analysis and immunostaining. Primary tubular epithelial cells (PTECs) were cultured from *Lrp5*$^{-/-}$ mice and WT mice. Co-Immunoprecipitation was performed in a human proximal tubular epithelial cell line (HKC-8) over-expressing LRP5 and TGF-β receptors.

Results: *Lrp5*$^{-/-}$mice with UUO showed ameliorated renal fibrosis and alleviated TGF-β signaling compared with WT mice with UUO. However, activation of the Wnt/β-catenin signaling was not different between *Lrp5*$^{-/-}$ mice and WT mice, indicating that attenuated tubulointerstitial fibrosis in *Lrp5*$^{-/-}$ mice was not due to mitigated activation of the fibrotic Wnt/β-catenin pathway. Instead, LRP5$^{-/-}$/UUO kidneys displayed alleviated TGF-β signaling in comparison to that in WT/UUO kidneys. Overexpression of LRP5 in HKC-8 resulted in enhanced TGF-β signaling including enhanced TGF-β-driven transcriptional activity and elevated expression of fibrosis markers regulated by TGF-β signaling. Knock-down of LRP5 in HKC-8 cells diminished the activation of the TGF-β signaling pathway. Meanwhile, *LRP5*$^{-/-}$ PTECs also displayed attenuated activation of the TGF-β signaling, compared to WT PTECs. In addition, immunoprecipitation assay demonstrated physical association between LRP5 and TGF-β receptor I, suggesting that LRP5 might act as a co-receptor of the TGF-β signaling pathway in the regulation of tubulointerstitial fibrogenic process.

Conclusions: LRP5 promotes tubulointerstitial fibrosis via regulation of the TGF-β signaling. This activity is independent of its role in the Wnt/β-catenin pathway.

Loss of Endothelial Nitric Oxide Augments Smad3 Linker Phosphorylation and Precedes Insulin Resistance in High-Fat Diet Induced Obesity Yu bo yang Sun, Xinli Qu, Jinhua Li. *Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia.*

Background: Deficiency of endothelial nitric oxide synthase (NOS3/eNOS) confers susceptibility to diet-induced obesity and it's complications. eNOS-derived nitric oxide (NO) acts as a potent vasodilator, enhances insulin sensitivity and also inhibits inflammation. TGF-β/Smad signaling plays an important role in regulating glucose and energy homeostasis. Smad3 deficient mice are protected from diet-induced obesity and obesity-related kidney injury. This study investigated whether the loss of endothelial-derived NO promotes Smad3 activation, which precedes insulin resistance in high-fat diet (HFD) induced obesity.

Methods: C57B6L/J wild type, eNOS deficient (eNOS-/-) with C57B6L/J background mice were given HFD or normal diet (ND) treatment for 1, 3, 7 days and 4, 8 or 16 weeks.

Results: Within 7 days of HFD treatment in WT mice, Western blotting showed a marked decrease in total eNOS level. Phosphorylation of Smad3 linker region was only seen 4 weeks after HFD treatment, indicating endothelial injury precedes phosphorylation of Smad3 linker region. Compared to WT mice, eNOS-/- mice on HFD showed early onset of peripheral and renal insulin resistance, increased microalbuminuria, elevated blood pressure, which suggested that endothelial injury drives renal metabolic disorders induced by HFD. Confocal microcopy demonstrated that fibronectin and collagen IV significantly increased in glomeruli in the HFD-treated eNOS-/- group compared to that in HFD-treated WT group. An *in vitro* model, palmitate acid addition to culture endothelial cells induced rapid C-terminal phosphorylation of Smad3, subsequent loss of eNOS, phosphorylation of Smad3 linker region and insulin resistance. L-NAME, a specific NOS inhibitor, significantly increased phosphorylation of Smad3 linker region and insulin resistance. Finally, endothelial cell overexpressing eNOS significantly inhibited Smad3 linker region phosphorylation and protected insulin sensitivity.

Conclusions: In summary, our studies showed that eNOS and Smad3 signaling pathway play essential roles in HFD-induced renal injury. eNOS/Smad3 pathway may be a novel therapeutic target in obesity-related kidney disease.

FR-PO286

HIF1α and HIF2α Both Mediate Glomerulosclerosis but Differentially Regulate the COL1A2 Promoter Bethany Baumann, Tomoko Hayashida, Xiaoyan Liang, H. William Schnaper. *Northwestern Univ, Chicago, IL.*

Background: TGFβ increases HIF1α and HIF2α levels in normoxia and both HIFs contribute to TGFβ induction of type I collagen *in vitro*, suggesting a potential role for HIFs in renal disease regardless of oxygen tension. Here, we studied the role of HIFs in mouse glomerulosclerosis (GS).

Methods: HIF1a$^{f/f}$ or $^{f/+}$, bactin-Cre-ERT2, NEP25 mice express human Tac on podocytes. LMB2, a toxin/anti-Tac chimera, binds to Tac, ablating podocytes to cause GS. Systemic Cre recombination was induced by tamoxifen at 4 weeks of age and LMB2 injected at 9 weeks. Mice were sacrificed 4 weeks later. HIF2a$^{f/f}$ or $^{f/+}$ mice were generated on a 129 background and bred with PDGFRβ-Cre mice to delete HIF2α from pericytes and mesangial cells. GS was induced by Adriamycin injection at 8 weeks of age. Mice were sacrificed 2 weeks later. Disease progression was analyzed by histology, scoring 50-100 glomeruli/animal on a fibrosis scale of 0-4, and by qPCR for COL1A2 mRNA with laser-captured glomeruli. *In vitro* studies investigating a mechanism by which HIFs regulate COL1A2 promoter were also performed.

Results: HIF1α: Histologically, control mice scored 0.46 (+/- 0.12), diseased WT mice 3.13 (+/- 0.19), and diseased HIF1α KO mice 1.42 (+/- 0.28). Glomerular COL1A2 mRNA with LMB2 injection was increased 3.4x over the healthy controls in WT, but only 1.9x with HIF1α KO. *In vitro*, TGFβ induced COL1A2 promoter activity by 2.4x, which was abrogated when a hypoxia response element (HRE) 335 bp 5' to the transcription start site was mutated. By DNA precipitation assay, HIF1a binding to a -335 COL1A2 HRE probe was detected after TGFβ treatment. Interestingly, Smad3 also bound the -335 COL1A2 HRE probe in both TGFβ-treated cell lysate and whole kidney lysate from WT HIF1α NEP25 mice with GS. **HIF2**α: HIF2a$^{f/f}$PDGFRβ-Cre mice showed less GS than HIF2α$^{+/+}$ mice by histology. *In vitro,* HIF2α enhanced COL1A2 promoter activity independently of the -335 HRE. Instead, HIF2α increased the transcriptional activity of Smad3.

Conclusions: Both HIF1α and -2α contribute to the development of GS in mice. Our *in vitro* studies strongly suggest that HIF1α and -2α each enhance TGFβ-mediated fibrogenesis, but through distinct mechanisms.

FR-PO287

MiR302a-3p Modulates Renal Epithelial-Mesenchymal Transition in DKD by Targeting ZEB1 Wenbin Tang, Linfeng Zheng, Renheng Yan, Jiayi Yang, Linlin Peng, Qiaoling Zhou, Liping Chen. *Dept of Nephrology, Xiangya Hospital, Central South Univ, Kidney Inst, Changsha, Hunan, China.*

Background: Recent study found that miRNAs are involved in diabetic kidney disease (DKD). The objective of this study is to determine the role of miR302a-3p in the process of renal epithelial-mesenchymal transition (EMT) in DKD.

Methods: The levels of miR302a-3p in the plasma of DKD patients were detected by realtime PCR and the relationship of miR302a-3p and UAE or eGFR were analyzed. Secondly, miR302a-3p expression was determined in HK-2 cells treated with high glucose for different time. And then miR302a-3p mimics and inhibitor were transfected to HK-2 cells following exposure to high glucose and low glucose respectively. The expressions of ZO-1, vimentin and ZEB-1 were determined by realtime PCR and western blot.

Results: The expression of circulating miR-302a-3p was significantly increased in the diabetes mellitus group (DM,n=22) compared with control (healthy persons, n=30) and then decreased in the early stage of diabetic nephropathy group (DNE, n=20). Furthermore, its expression in clinical diabetic nephropathy group (DNC, n=18) was decreased significantly compared with DM group. Circulating miR-302a-3p had negative relevance with UAE in DNE group(r=-0.649, P=0.002) and DNC group(r=-0.681, P=0.006); It had positive relevance with eGFR in DNC group(r=0.486,P= 0.041). In vitro, miR-302a-3p expression in HG group increased at 6h and aescended to the highest level at 12h and then gradually decreased at 48h and 72h. More interesting, ZEB1 protein expression had an opposite change which gradually decreased from 6h to 24h and then gradually increased from 48h to 72h. Moreover, overexpression of miR-302a-3p suppressed expression of ZEB1 in the post-transcriptional level and reversed high glucose-mediated downregulation of E-cadherin and upregulation of vimentin. Meanwhile, loss of miR-302a-3p expression can lead to EMT of HK-2 cells just as high glucose stimulation.

Conclusions: miR-302a-3p may play a protective role by targeting ZEB1 in renal epithelial- mesenchymal transition in DKD. It may serve as a potential novel target in pre-EMT states for the amelioration renal fibrosis seen in DKD.

Kruppel-Like Factor 15 Works as an Early Anti-Fibrotic Transcriptional Regulator in Angiotensin II-Induced Renal Fibrosis via Down-Regulation of Connective Tissue Growth Factor Xiangchen Gu,[1] Xiang Gao,[1] Changlin Mei.[1] *[1]Kidney Inst of PLA, Dept of Medicine, Changzheng Hospital, Second Military Medical Univ, Shanghai, China; [2]Kidney Inst of PLA, Dept of Medicine, Changzheng Hospital, Second Military Medical Univ, Shanghai, China; [3]Kidney Inst of PLA, Dept of Medicine, Changzheng Hospital, Second Military Medical Univ, Shanghai, China.*

Background: Angiotensin II (Ang II) has been regarded as an important profibrogenic cytokine in renal fibrosis. One of the main targets of Ang II in renal fibrosis is CTGF. Krüppel-like factor 15 (KLF15) is recognized as an important negative transcription factor in renal fibrosis. This study is aimed to detect the possible role and mechanism of KLF15 in renal fibrosis induced by Ang II.

Methods: Firstly, mice were randomized into control group, Ang II group, Ang II+losartan group, the renal fibrosis levels and KLF15 were measured by Real-Time PCR and IMF methods respectively at 4 weeks or 6 weeks. Then NRK-49F were stimulated with Ang II and (or) infected with Ad-GFP-KLF15, and the expressions of KLF15, CTGF and extracellular matrix were detected by Real-Time PCR and Western Blot. CoIP and ChIP assay were also performed to investigate the relationship among coactivator P/CAF, transcription regulator KLF15, and CTGF promoter.

Results: The murine model of Ang II-induced renal fibrosis demonstrated a significant decrease in renal KLF15 expression at 4 weeks and progressive renal fibrosis at 6 weeks. Losartan effectively prevented the decrease in KLF15 expressions induced by Angiotensin II. Stimulated with Ang II, NRK-49F exhibited significant decreases in KLF15, accompanied by a marked increase in CTGF and extracellular matrix. Losartan prevented the decrease in Ang II induced KLF15. Furthermore, overexpression of KLF15 inhibited Ang II induced CTGF in NRK-49F. CoIP and ChIP demonstrated KLF15, could directly bind to P/CAF, and repressed its recruitment to CTGF promoter.

Conclusions: These results unveiled that Ang II could downregulate KLF15 via AT1 receptor. Transcription repressor KLF15 is likely to inhibit Ang II induced CTGF by repressing coactivator P/CAF's recruitment to CTGF promoter.

Biomarkers of Collagen Type III and VI Turnover Can Identify Renal Allograft Failure in Kidney Transplant Recipients Federica Genovese,[1] Signe Holm Nielsen,[1,2] Daniel Guldager Kring Rasmussen,[1,3] Morten Asser Karsdal,[1] Stephan J.L. Bakker,[4] Peter Olinga,[4] Elisabeth G.D. Stribos,[4] Henricus A.M. Mutsaers.[4] *[1]Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; [2]System Biology, Denmark Technology Univ, Kgs. Lyngby, Denmark; [3]Southern Denmark Univ, Odense, Denmark; [4]Univ of Groningen, Groningen, Netherlands.*

Background: Chronic allograft loss poses a major problem in improving long-term survival in renal transplant recipients (RTR). Interstitial fibrosis and tubular atrophy are already present in 40% of kidney allografts 3-6 months after transplantation. Extracellular matrix (ECM) turnover levels, reflecting the onset of fibrosis, can be early and superior prognostic markers for renal allograft function. We evaluated a non-invasive tool measuring the plasma and urinary biomarker profile related to ECM turnover.

Methods: 78 patients attending the University Medical Center Groningen during one week for a routine check-up after kidney transplantation were enrolled in the study. Plasma and/or 24h-urine samples were collected from 75 and 42 RTR, respectively. Afterwards, markers of collagen remodeling were determined by competitive ELISAs.

Results: There was no correlation between age or time after transplant and glomerular filtration rate (eGFR) in this population. Urinary levels of C3M, a marker for collagen type III degradation, were strongly correlated with eGFR ($p<0.0001$), with lower levels in advanced disease stages compared to early and mild stages. Plasma levels of Pro-C6, a marker for collagen type VI formation, significantly increased with disease progression and strongly correlated with eGFR ($p<0.0001$). In contrast, plasma C3M and urinary Pro-C6 levels showed no correlation with renal function.

Conclusions: We identified two biomarkers of tissue turnover associated with ECM remodeling and subsequent fibrosis in the transplanted kidney leading to loss of renal function. As such they have great potential as early diagnostic markers for kidney allograft failure.

FR-PO290

Hyaluronidase-2 Dependent Regulation of CD44 Variant Expression in Anti-fibrotic versus Pro-Fibrotic Cells Soma Meran, Adam Midgley, Robert Steadman, Aled O. Phillips. *Nephrology, Cardiff Univ, Cardiff, United Kingdom.*

Background: Hyaluronan (HA) is a GAG with increased expression in progressive renal disease, and its expression correlates with poor renal outcomes. The HA receptor (CD44) is a transmembrane protein that can undergo alternative exon splicing to produce over 20 CD44 variant isoforms. We identified that the standard isoform (CD44s) is critical for myofibroblast formation, whereas the variant isoform (CD44v7/8) promotes reversal of myofibroblast phenotype. Hyaluronidase-(Hyal)2 is a weak HA degrading enzyme and is a key mediator in reversal of myofibroblast phenotype, but its mechanism is unknown. Here we investigate whether Hyal2 plays a regulatory role in alternative splicing of CD44v7/8 variant isoform expression.

Methods: Fibroblasts & renal epithelial cells were incubated with TGFb1 to induce myofibroblast formation, and compared to cells incubated with TGFb1 & BMP7 to induce myofibroblast reversal. QPCR, confocal microscopy, ChIP, siRNA & plasmid overexpression were used to assess Hyal2 effects.

Results: Hyal2 was upregulated by both profibrotic (TGFb1) & anti-fibrotic (BMP7) cellular treatments. However in profibrotic cells, Hyal2 was cytoplasmic, whereas in antifibrotic cells Hyal2 translocated to the nucleus. In profibrotic cells Hyal2 did not associate with CD44. In contrast in antifibrotic cells Hyal2 associated with CD44s at the nucleus, whilst CD44v7/8 located to the cell surface. In antifibrotic cells Hyal2 nuclear translocation was crucial for increased CD44v7/8 mRNA & protein expression. CD44v7/8 was subsequently necessary for HA internalization and consequent reversal of myofibroblast phenotype. ChIP demonstrated association between Hyal2 and introns flanking the CD44v7/8 exon nucleotide sequence similar to Ago2 splice facilitator. Moreover, Hyal2 inhibition attenuated BMP7 driven upregulation of splice regulators SLM2 & SRSF6.

Conclusions: Hyal2 displays nonenzymatic activity & translocates to the nucleus regulating expression of CD44v7/8 splice variant, which is crucial for reversing myofibroblast phenotype. Hence Hyal2 is a novel splice regulator and a critical regulator in reversal of myofibroblast phenotype & fibrosis prevention.

FR-PO291

FGF Signaling Contributes to Podocyte Injury in Murine HIV-Associated Nephropathy Koji Okamoto,[1] Eisei Noiri,[2] Jeffrey B. Kopp.[1] *[1]Kidney Section, NIDDK, NIH, Bethesda, MD; [2]Dept of Nephrology, Endocrinology, Hemodialysis & Apheresis, Univ Hospital, The Univ of Tokyo, Tokyo, Japan.*

Background: We reported that fibroblast growth factor receptor (FGFR), its ligand fibroblast growth factor 2 (FGF2), and their amplifying co-factor glypican 5 (GPC5) play important roles in idiopathic nephrotic syndrome and diabetic nephropathy (Okamoto, Nature Genetics, 2011). We have investigated the role of the FGF2 signal pathway in HIV-associated nephropathy (HIVAN).

Methods: FGF2 ligands and FGFR expression were studied in a mouse podocyte cell line and a HVAN transgenic mouse, both of which express the HIV accessory protein Vpr in the presence of doxycycline. To study FGF2 trapping in glomeruli, biotinylated FGF2 was administered intravenously and detected with fluorescent streptavidin. Vpr mice and control mice received FGF2 (5 mg/animal/weekly for 4 weeks) or FGF antagonist (PD173074, 50mg/animal/ bi-weekly for 4 weeks.

Results: In cultured mouse podocytes FGFR3 mRNA was increased 11-fold after Vpr induction. In Vpr mice compared with control mice, renal cortex FGF2 content was increased 3-fold, as assessed by ELISA. Intra-glomerular protein expression of FGFR3 and GPC5 were increased, as detected by immunofluorescent staining. These results suggest that Vpr mouse glomeruli might have increased FGF2 binding capacity and so we tested the binding capacity of FGF2 in vivo. One hour after intravenous administration of biotinylated FGF2, more biotin signal remained in glomeruli of Vpr mice compared with control mice (60% increase). Urine albumin/creatinine ratios (g/g) were significantly increased in FGF2-treated Vpr mice compared to untreated Vpr mice on day 14 (0.55±0.19 vs 2.3±0.6), day 21 (1.17±0.16 vs 18.7±5.1) and day 28 (1.87±0.44 vs 21.8±9.9). Further, the FGF antagonist decreased albuminuria in Vpr mice at day 21 (0.47±0.16 vs 1.1.7±0.16 g/g) and at day 28 (0.36±0.41 vs 1.87±0.44 g/g).

Conclusions: In a HIVAN mouse model, podocyte Vpr expression increased protein expression of FGF2, FGF receptors and GPC5. Administration of FGF2 increased albuminuria, and treatment with an FGF antagonist reduced albuminuria, suggesting a pathogenic role for FGF2 in this murine HIVAN model.

FR-PO292

Role of AMP-Activated Protein Kinase Signaling in Fibroblast Activation and Renal Fibrosis Yuguo Wang, Yanlin Wang. *Medicine, Baylor College of Medicine, Houston, TX.*

Background: Renal fibrosis is a common manifestation of chronic kidney disease resulting in progressive loss of kidney function. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the molecular mechanisms underlying fibroblast activation are not fully understood. In this study, we examined the functional role of AMP-activated protein kinase a1 (AMPKa1) in the activated of fibroblasts and the development of renal fibrosis.

Methods: To examine the functional role of AMPKa1, we generated mice with fibroblast-specific deletion of AMPKa1 using Cre-LoxP strategy. Unilateral ureteral obstruction (UUO) and ischemia-reperfusion injury (IRI) models were used to induce renal fibrosis. Cultured cells were used to examine AMPKa1 signaling in fibroblast activation.

Results: AMPKa1 is induced in the kidney during the development of renal fibrosis. Mice with mesenchymal-specific deletion of AMPKa1 were born normal and had no obvious morphological abnormality in the kidney. Compared with Cre negative, floxed AMPKa1 mice, mice with fibroblast-specific deletion of AMPKa1 exhibited fewer α-smooth muscle actin (α-SMA) positive myofibroblasts and expressed less α-SMA protein in the kidney following UUO or IRI. Furthermore, mesenchymal-specific deletion of AMPKa1 significantly reduced total collagen deposition and suppressed expression of extracellular matrix proteins (collagen I and fibronectin) in the kidney in response to UUO or IRI. In cultured fibroblasts, activation of AMPKa1 caused cofilin phosphorylation, cytoskeleton remodeling, and myocardin-related transcription factor A (MRTF-A) nuclear translocation leading to fibroblast activation and extracellular matrix protein production.

Conclusions: Our results have shown that AMPKa1 is critically involved in fibroblast activation through regulation of cytoskeleton dynamics and MRTF-A nuclear translocation. Therefore, AMPKa1 may represent a novel therapeutic target for chronic kidney disease.

Increased Expression of Complement C1 from Pericyte/Myofibroblasts Contributes to Renal Fibrosis via Activation of Wnt/β Catenin Signaling Sandhya Xavier,[1] Susan G. Landes,[1] Amandeep Bajwa,[1] Jing Yu,[2] Jeremy Stuart Duffield,[3] Didier Portilla.[1] *[1]Dept of Medicine and Center for Immunity, Inflammation and Regenerative Medicine, Univ of Virginia, VA; [2]Univ of Virginia; [3]Biogen Idec.*

Background: Pericytes/fibroblasts are progenitors of scar-forming cells known as myofibroblasts. We have characterized the inflammatory nature of pericytes/fibroblasts isolated from UUO mice. We have also shown that Wnt/β-catenin signaling is activated during kidney fibrosis. Role of complement C1 on pericyte function or in Wnt activation remains unknown.

Methods: We used the unilateral ureteral obstruction (UUO) and folic acid nephropathy models. Pericytes were isolated using magnetic beads containing anti-PDGFβ Receptor ab. Expression of C1 complex was examined by western blotting, immunofluorescence, and realtime-PCR in tissue and in cell lysates and supernatants obtained from pericytes cultured from sham, day3 and day10 UUO mice kidneys. Topflash reporter assays were used to study Wnt signaling.

Results: Expression of C1q chains a,b,c, as well as subunits C1r and C1s were increased during fibrosis along with increased expression of TGF-β, α-SMA and Wnt target genes wisp1 and 2. Immunostain showed C1q localization in the interstitial compartment of UUO but not in sham mice consistent with PCR and western blot data. In cultured pericytes, C1 complex component C1q protein was increased in culture supernatants of Day3 and Day10 but not in shams. Expression of C1q proteins was absent in supernatants of UUO pericytes isolated from C1qKO mice. Topflash reporter assays for Wnt signaling showed that pericytes from UUO kidneys had pronounced activation of the reporter following Wnt3a treatment as compared to shams, and this effect was blunted in pericytes isolated from C1qKO mice.

Conclusions: We demonstrate both in vivo and in vitro that increased expression of the C1 complex occurs in response to kidney injury along with activation of Wnt signaling. Given previous data, showing that inhibition of C1 complex using C1INH prevents renal fibrosis, we conclude that its inhibition in pericytes/myofibroblasts leads to inhibition of Wnt activation and reduced renal fibrosis.

The Role and Association of Inflammatory and Apoptotic Caspases in Tubulointerstitial Fibrosis Chun Zhang, You Ke, Hua Su. *Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: Caspases are a family of cysteine proteases with pivotal functions in apoptotic and inflammatory signaling. According to their difference of structures and functions, 14 mammalian Caspases are classified into three categories, which are apoptosis activator, apoptosis executioner and inflammatory mediator. Caspase-1 is an inflammatory caspase, and Caspase-7 belongs to apoptosis executioner. The roles and association of these two distinct types of Caspases protein in tubulointerstitial fibrosis (TIF) are not well recognized.

Methods: Unilateral Ureteral Obstruction (UUO) animal model was constructed on wild-type(WT) and caspase-1 knock out (KO) mice. In vitro study, the cultured tubular epithelial cell line NRK-52E (TECs) was employed and the expression of caspase-1 and caspase-7 was modulated by transfection of Lentiviral shRNA.

Results: In current study, we found both Caspase-1 and Caspase-7 protein levels were elevated in UUO WT mice. While in UUO mice with Caspase-1 KO background the increased Caspase-7 was suppressed significantly along with the minimized extracellular matrix accumulation which was demonstrated by western blot, immunohistochemistry and Masson trichrome staining. In vitro TGF-β1 stimulation promoted the expression of Caspase-1 and Caspase-7 simultaneously in TECs. Notably, genetic deletion of either Caspase-1 or Caspase-7 could abrogate TGF-β1 driven TECs' transdifferentition and apoptosis. In addition, knocking down Caspase-1 dampened Caspase-7 upregulation in TGF-β1 treated TECs which was consistent with in vivo study. However genetic deletion of Caspase-7 did not influence Caspase-1's abundance.

Conclusions: Our observation firstly links inflammatory and apoptotic Caspases together in TIF and further elucidates Caspase-1 activation is an upstream event of apoptotic Caspase-7 induction during TIF and TECs' transdifferentition and apoptosis.

MAD2B-SnoN-Smad3 Signaling Pathway Is Implicated in Fibroblast Activation and Tubulointerstitial Fibrosis Chun Zhang, Hui Tang, Hua Su. *Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.*

Background: Mitotic arrest deficient protein MAD2B, an anaphase-promoting complex (APC)/cyclosome inhibitor, is indispensible for mitotic checkpoint control. Previously we found MAD2B was expressed in glomerular and tubulointerstitial compartment. In addition our data indicated MAD2B was involved in podocyte injury triggered by high glucose. But its role in renal fibrosis remains elusive.

Methods: The object of this study included patients with renal tubulointerstitial fibrosis (TIF) (secondary glomerulonephritis and interstitial nephritis were excluded) , Unilateral Ureteral Obstruction(UUO) mice and in vitro cultured tubular epithelial cell line (NRK-52E) and renal fibroblast cell line (NRK-49F). In vivo gene silencing of MAD2B was carried out by intrarenal Lentiviral gene delivery.

Results: By immunohistochemistry and western blot, it showed the expression of MAD2B was increased obviously in TIF patients and UUO mice. Next we assessed the types of cells attributing to the elevated MAD2B abundance. It is well-known that TECs and fibroblast are the main culprits in TIF. Our data suggested under TGF-β1 exposure the level of MAD2B in NRK-52E was not altered, whereas in NRK-49F MAD2B was upregulated in a time dependent manner significantly. Furthermore TGF-β1 induced fibroblast activation can be abrogated by MAD2B genetic deletion. Intriguingly, SnoN, a repressor of Smad3, was decreased in NRK-49F cells treated with TGF-β1 which could be alleviated by MAD2B knocking down. Consistently, in UUO mice the expression of SnoN was significantly reduced in renal cortex accompanying with enhanced p-Smad3. And locally genetic deletion of MAD2B by Lentiviral transfection preserved SnoN abundance and consequently suppressed Smad3 signaling which finally dampened the fibroblast activation and ECM accumulation in UUO mice.

Conclusions: Our observation proposes that MAD2B participates in fibroblast activation and tubulointerstitial fibrosis by repressing SnoN and subsequent activating Smad3 signaling pathway. Regulation of MAD2B-SnoN pathway may be a promising therapy for tubulointerstitial fibrosis. However, the regulatory mechanisms between MAD2B and SnoN still need further investigation.

Losartan Reduces Renal Fibrogenesis by Up-Regulating Klotho in Uremic Rats Edgar Maquigussa, Josne Carla Paterno, Gabriel H. Pokorny, Mariana S. Perez, Nestor Schor, Mirian A. Boim. *Nephrology, UNIFESP, Sao Paulo, Brazil.*

Background: Klotho is a transmembrane protein expresses mainly in the kidney. Soluble klotho acts as an endocrine factor with diverse functions through mechanisms involving Wnt and TGFb1 signaling. Renal fibrosis is the end stage of the progressive chronic kidney disease (CKD) and renal klotho is markedly decreased in CKD patients. Renin angiotensin system (RAS) blockade is a relevant therapy to reduce CKD progression and the beneficial effects go further to the antihypertensive effect. The aim of this study was to investigate a possible link between RAS and Klotho by evaluating the effects of losartan on Klotho/Wnt signaling in 5/6 nephrectomy model of CKD in rats.

Methods: Adult male Wistar rats were underwent 5/6 nephrectomy (Nx). The Nx animals were separated into three groups: control, with no treatment (Nx), treated with losartan (LOS; 25 mg/kg/day, p.o.) or propranolol (PROP; 25mg/kg/day, p.o.). Results were compared with SHAM group. Blood pressure was measured by tail-cuff plethysmography. After 8 weeks, animals were sacrificed and the remmnant kidney was removed to determine the renal expression of collagen, fibronectin, epithelial-to-mesenchymal transition (EMT) markers (FSP1 and a-SMA) and Klotho signaling (Klotho, Wnts and GSK3β) by real time PCR.

Results: Nx rats presented hypertension that was blunted by both losartan and propranolol. The expression levels of collagen and fibronectin were increased in Nx group which was reverted only in LOS group. The presence of the EMT markers, FSP1 and a-SMA , was observed in Nx group which was decreased with losartan treatment. Klotho was reduced in Nx animals and LOS but not propranolol significantly increased klotho expression. Nx animals showed uperegulation of GSK3β, Wnt 7a and Wnt 3. LOS treatment prevented the increase in Wnt 7a and GSK3β but not Wnt 3.

Conclusions: These data suggest that the beneficial effect of losartan on renal fibrosis is independente of blood pressure reduction and may be, at least in part, due to upregulation of klotho. Since, the antihypertensive agent, propranolol induced no change in klotho expression. The interation between the RAS and Klotho can inactivacte the Wnt pahtway.

FR-PO297

PBI-4050 Inhibits the Development of Renal Fibrosis in a Model of Tubulointerstitial Fibrosis Ming-Zhi Zhang,[1] Lyne Gagnon,[2] Raymond C. Harris.[1] *[1]Medicine, Vanderbilt Univ, Nashville, TN; [2]ProMetic Biosciences, Laval, QC, Canada.*

Background: Kidney fibrosis occurs in chronic kidney diseases and leads to gradual loss of kidney function. Although the etiology of kidney fibrosis is multifactorial, there is increasing evidence linking chronic inflammation to kidney fibrosis. PBI-4050, a novel first-in-class orally active low molecular weight compound currently in phase II clinical trials, has anti-fibrotic and anti-inflammatory properties in different *in vivo* models. Activation of epidermal growth factor receptor (EGFR) contributes to the development of renal fibrosis, and homozygous transgenic mice with overexpression of an EGFR ligand, human heparin-binding EGF (HB-EGF), in renal proximal tubule develop spontaneous tubulointerstitial fibrosis by 3-4 weeks of age. We examined whether PBI-4050 affected the development of renal fibrosis in homozygous HB-EGF mice.

Methods: Homozygous HB-EGF mice on a C57/BL6 background were treated with PBI-4050 (200 mg/kg/day) by daily gastric gavage from 4 to 14 weeks of age.

Results: Immunohistochemical analysis showed that in untreated homozygous HB-EGF mouse kidney, ERK was activated in both proximal tubule epithelial cells (PTEC) and their surrounding interstitial cells. PBI-4050 treatment led to marked decreases in ERK activity in proximal tubule epithelial cells and interstitial cells, suggesting that PBI-4050 inhibits not only HB-EGF/EGFR-mediated p-ERK activation in PTEC, but also subsequent ERK activation in the interstitial cells, leading to inhibition of the development of renal fibrosis. PBI-4050 treatment significantly reduced the development of renal interstitial fibrosis. PBI-4050 caused marked decreases in renal macrophage infiltration (F4/80 staining) as well as oxidative stress (nitrotyrosine staining). In addition, PBI-4050 treatment reduced the expression levels of the pro-fibrotic and fibrotic components including CTGF and TGF-β, α-SMA (a marker of myofibroblasts), fibronectin, collagen I and collagen IV.

Conclusions: These studies suggest that PBI-4050 significantly inhibits the development of renal fibrosis in homozygous HB-EGF mice through multiple mechanisms, including through anti-inflammatory effects.

FR-PO298

FHL2 Promotes Tubular Epithelial-to-Mesenchymal Transition by Regulating β-Catenin Activity Ting Cai, Danqin Sun, Chunsun Dai, Junwei Yang, Weichun He. *Center for Kidney Disease, 2nd Affiliated Hospital of Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Fibrotic kidneys exhibit aberrant activation of β-catenin signaling, one of the main pathways that play a critical role in mediating tubular epithelial-to-mesenchymal transition (EMT). FHL2 (four-and-a-half-LIM-only protein 2), an adapter protein, is an endogenous regulator of β-catenin.

Methods: To determine whether FHL2 is also involved in the EMT process, we investigated its regulation and function during TGF-β1-stimulated EMT.

Results: TGF-β1 induced FHL2 mRNA and protein expression in rat proximal tubular epithelial cells (NRK-52E) in a time- or dose- dependent fashion, an effect that was largely dependent on intracellular Smad signaling. Overexpression of FHL2 suppressed E-cadherin, increased α-smooth muscle actin (α-SMA), vimentin and fibronectin expression, whereas knockdown of FHL2 *via* small interfering RNA partially reduced TGF-β1-mediated α-SMA, vimentin and fibronectin expression, and restored E-cadherin. TGF-β1 induced FHL2 physically interact with β-catenin in the nuclei in NRK-52E cells. Ectopic expression of FHL2 promoted β-catenin nuclear translocation, induced β-catenin-mediated gene transcription, and upregulated the expression of β-catenin target genes such as plasminogen activator inhibitor-1 (PAI-1) and Twist. Conversely, downregulation of FHL2 expression reduced β-catenin nuclear translocation, abolished β-catenin-mediated gene transcription, and inhibited PAI-1 and Twist expression in the basal and TGF-β1-stimulated conditions. In a mouse model of obstructive nephropathy, FHL2 expression increased in a time-dependent manner, suggesting that it may play a role in tubular EMT and renal fibrosis *in vivo*.

Conclusions: We conclude that FHL2, through manipulating β-catenin activity, plays an important role in regulating TGF-β1-mediated EMT and could be a potential future therapeutic target to prevent progression of renal fibrosis.

Funding: Government Support - Non-U.S.

FR-PO299

Depletion of Endothelial Sirtuin 1 Aggravates Capillary Rarefaction and Tissue Fibrosis following Kidney Injury Yujiro Kida, Michael S. Goligorsky. *New York Medical College.*

Background: Capillry rarefaction and tissue fibrosis are hallmarks of chronic kidney diseases. Although recent studies point to sirtuin 1 (SIRT1) in endothelial cells as being protective against tissue injury, mechanisms of this effect are incompletely understood.

Methods: We deleted SIRT1 catalytic domain in endothelial cells in mice (Sirt1 mutant mice). Both wild type control and Sirt1 mutant mice were subjected to kidney injury by unilateral ureteral obstruction (UUO). In in vitro studies, we used human umbilical vein endothelial cells (HUVECs).

Results: After UUO kidney injury, compared to control kidneys, Sirt1 mutant kidneys demonstrated significantly exaggerated (1) capillary rarefaction (2) expansion of myofibroblast population, and (3) tissue fibrosis compared to wild type kidneys. In HUVECs, siRNA knockdown or chemical inhibition of SIRT1 significantly suppressed transcriptional expression of platelet derived growth factor-β (PDGF-B) and vascular endothelial growth factor receptor-2 (VEGFR2). Both effects were partially abrogated by Notch inhibition. This indicates that SIRT1 enhances PDGF-B and VEGFR2 expression via Notch inhibition in endothelial cells. In scratch wound healing assay, SIRT1 inhibition impaired migration of HUVECs under oxidative stress by hydrogen peroxide, indicating SIRT1 dysfunction decreases migratory phenotype of endothelial cells. In transwell co-culture assay, endothelial SIRT1 inhibition impaired recruitment of PDGFRβ+ cells to HUVECs. Consistent with this finding, detachment of PDGFRβ+ pericytes was increased in Sirt1 mutant kidneys compared to control kidneys, suggesting that pericyte detachment and subsequent pericyte-myofibroblast transition are augmented in Sirt1 mutant kidneys, resulting in excessive fibrosis.

Conclusions: Functional depletion of SIRT1 in endothelial cells aggravates capillary rarefaction and fibrosis at least in part due to impaired endothelial expression of VEGFR2 and PDGF-B, respectively.

In Vivo Reprogramming of Myofibroblasts with Endothelial Progenitor Cell Extract Ameliorates Fibrosis Kei Matsumoto,[1,2] Sandhya Xavier,[1] Jun Chen,[1] Yujiro Kida,[1] Brian B. Ratliff,[1] Stefan Rose-john,[3] Michael S. Goligorsky.[1] *[1]New York Medical College; [2]Showa Univ, Tokyo, Japan; [3]Christian-Albrechts Univ, Kiel, Germany.*

Background: Accumulation of myofibroblasts is a hallmark of renal fibrosis. We hypothesized that exposing myofibroblasts to the extract of endothelial progenitor cells (EPC extract) could reverse endothelial-mesenchymal transition.

Methods: We used α-SMA-GFP mice to visualize fibroblast-to-myofibroblast conversion and embryonic mouse EPC to prepare extract. Cell phenotype was assessed using standard biochemical and molecular biology techniques.

Results: In vitro treatment of TGF-β1-activated fibroblasts with EPC extract prevented expression of α-SMA, but did not enhance expression of endothelial markers. In two distinct models of renal fibrosis, unilateral ureteral obstruction (UUO) and chronic phase of folic acid-induced nephropathy (FAN), subcapsular injection of EPC extract to the kidney prevented and reversed accumulation of α-SMA-positive myofibroblasts and reduced fibrosis. Screening the composition of EPC extract for cytokines revealed that it is enriched in LIF and VEGF. Only LIF was capable of reducing fibroblast-to-myofibroblast transition of TGF-β1-activated fibroblasts. In vivo subcapsular administration of LIF reduced the number of myofibroblsts, improved the density of peritubular capillaries, but did not reduce the degree of fibrosis. Effects of LIF, as well as Hyper-IL-6, in the presence of TGF-β1 were mediated via gp130/STAT3 pathway resulting in induction of pluripotency transcription factors KLF4, c-Myc, OCT4, and Nanog in association with the open chromatin conformation.

Conclusions: EPC extract does not reverse endothelial-mesenchymal transition, but it prevents and reverses fibroblast-to-myofibroblast transition and renal fibrosis. The component of EPC extract, LIF, is capable of preventing development of the contractile phenotype of activated fibroblasts, but does not eliminate TGF-β1-induced collagen synthesis in cultured fibroblasts and models of renal fibrosis. LIF component of EPC extract is a participant of its antifibrotic effect, but not the sole one, as other yet undisclosed factors contribute to the antifibrotic effect of the extract.

Mitochondrial Metabolic Switch to Glycolysis in Proximal Tubular Epithelial Cell in Fibrotic Kidneys

Lei Jiang, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Renal proximal tubule is susceptible to hypoxic injury since its reliance on aerobic oxidative metabolism. Mitochondrial dysfunction contributes to progression of chronic renal disease. However, the profile of the energy metabolism of renal tubule in progression of fibrosis is uncertain, and the relationship between the change of energy metabolism and tubular epithelial cell damage is unclear.

Methods: Gene expression profiles related to energy metabolism of the proximal tubule in fibrotic kidneys were analized. 2-Deoxyglucose (2-DG) was given to CD-1 mice under UUO intraperitoneally. Primary tubular epithelial cells (PTC) cultured from normal CD-1 mice renal cortex was used. 2-DG (inhibitor of glycolysis), bromopyruvic acid (inhibitor of hexokinase), dichloroacetic acid (inhibitor of glycolysis), oligmycin (inhibitor of oxidative phosphorylation), etomoxir (inhibitor of fatty acid oxidation), DON (inhibitor if glutamine metabolism), PKM2 siRNA or HIF-1a siRNA was used in PTC with or without TGF-β1 stimulation. The oxygen consumption rate (OCR) and extracellular acidification rate (ECR) were detected by Seahorse Metaboic Analyzer.

Results: 1.Glycolysis was upregulated in the proximal tubule in fibrotic kidney. 2.Genes related to gycolysis were upregulated, however, genes related to oxidative phosphorylation, fatty acid metabolism and glutamine metabolism were downregulated. The key limiting-rate enzymes for glycolysis were upregulated in the fibrotic kidney. 3.2-DG could block the renal fibrosis under UUO. 4.OCR was decreased under TGF-β1 stimulation in PTC, however, ECAR was increased after TGF-β1 stimulation. 5. Inhibiting oxidative phosphorylation, fatty acid oxidation or glutamine metabolism could increase the lactate production in PTC. Lactate could directly induce PTC damage. 6. Inhibiting glycolysis could ameliorate the damage of PTC under TGF-β1 incubation.

Conclusions: The mitochondrial metabolism including oxidative phosphorylation, fatty acid oxidation and glutamine metabolism is defective in proximal tubular epithelial cell in fibrotic kidney. The metabolism is switch to glycolysis, and the glycolytic product lactate further aggravates the injury.

The Effects of CCN3/NOV on the Formation of Extracellular Matrix in Human Mesangial Cells

Haifei Liu, Long Chen, Hong Liu, Bi-Cheng Liu. *Dept of Nephrology, Zhong Da Hospital, Southeast Univ, Nanjing, jiangsu, China.*

Background: Glomerulosclerosis is characterized by mesangial cells proliferation and progressive extracellular matrix (ECM) accumulation . Mesangial cells are activated in a variety of damage factors, leading to ECM deposition. ECM accumulation is the net result of the balance between synthesis and degradation. CCN3, a matricellular protein of the CYR61-CTGF-NOV (CCN) family, associates specifically with ECM. A recent study found that treatment with the matricellular protein CCN3 can block and/or reverse fibrosis development in obesity with diabetic nephropathy. However, whether CCN3 can alleviate the formation of glomerulosclerosis by inhibiting the production of ECM and/or promoting the degradation of ECM is still unknown. This study aims to explore the potential role of CCN3 in ECM accumulation of mesangial cells induced by TGF-βeta.

Methods: Human mesangial cells lines were stimulated with TGF-βeta (2ng/ml) and CCN3 for different concentration (5 to 500 ng/ml) after 24 hours of serum starvation. The expressions of fibronectin (FN), type I collagen (COLI), matrix metalloproteinase-2 (MMP-2), matrix metalloproteinase-9 (MMP-9) and tissue inhibitor of metalloproteinase-1 (TIMP-1) were evaluated with RT-PCR and Western blot.

Results: In human mesangial cells lines, TGF-βeta significantly upregulated FN, COLI and TIMP-1 at mRNA and protein levels ($P < 0.05$). However, a 1-hour pretreatment of the cells with CCN3 for different concentration (5, 50, 500 ng/ml) virtually blocked this TGF-βeta induced effect on them ($P < 0.05$). On the other hands, TGF-βeta downregulated MMP-2 and MMP-9 at mRNA and protein levels, whereas a 1-hour pretreatment of the cells with CCN3 for different concentration (5, 50, 500 ng/ml) enhanced the expression of MMP-2 and MMP-9 ($P < 0.05$).

Conclusions: This study identifies that CCN3 as a new actor alleviates the formation of glomerulosclerosis by inhibiting the production of ECM and promoting the degradation of ECM.

FR-PO303

Spleen Tyrosine Kinase (Syk) Inhibition Suppresses Renal Fibrosis Through Anti-Inflammatory Effects and Down-Regulation MAPK-p38 Pathway

Kuan-hsing Chen, Hsiang-Hao Hsu, Cheng-chieh Hung. *Nephrology, Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: Spleen tyrosine kinase (Syk) is a 72-kDa, a member of the Src family of non-receptor tyrosine. The central role of Syk in signaling processes is known to be involved in adaptive immunity, but also in autoinflammatory and allergic disease. However, the possible role of the anti-fibrogenic properties in renal interstitial fibrosis had not been established.

Methods: In vitro study: Cultured rat renal interstitial fibroblasts (NRK-49F) were stimulated with recombinant human TGF-β1 1ng/ml for different periods before harvesting. Alternatively, NRK-49F cells were pre-incubated with Syk inhibitor for 30 mins before TGF-β1 treatment. Total RNA was extracted for RT-PCR and total cell lysates were extracted for Western Blot analysis. In vivo study: Urinary unilateral obstruction model was induced in adult male *B6 mice*[/italic](3–5 months, 20–25 g). Mice with UUO were given with intra-peritoneal Syk inhibitor (20 and 40 mg/kg, bid) or saline daily, one day prior the UUO surgery. Both obstructed and contralateral kidneys were harvested 7 days after surgery. Kidney tissues were prepared for further pathological and molecular biological analysis.

Results: Our results demonstrated that the inhibition of Syk in NRK49F cells inhibited the stimulation effect of TGF-β leading to fibroblast transition to the myofibroblast phenotype (upregulation of α-SMA) and extracellular matrix proteins accumulation, collagen type I, type IV. In addition, in UUO model, Syk inhibitor attenuated the tubule-interstitial fibrosis and expression of α-SMA, collagen I and fibronectin in UUO kidney. The anti-fibrosis of Syk inhibitor in UUO model may be related to anti-inflammatory effects (down-regulate inflammatory cytokines and reduce macrophage infiltration). Moreover, the effects of Syk inhibitor in inhibition of kidney myofibroblast activation by TGF-β1 were associated with down-regulation of MAPK-p38 pathways.

Conclusions: In conclusion, we demonstrated that Syk inhibitor ameliorates TGF-β1 induced kidney myofibroblast activation and also reduces the tubulointerstitial fibrosis in UUO mice. The mechanisms may be related to anti-inflammatory effects and down-regulate MAPK-p38 pathway.

Optimization of Identification of the Glomerular Extracellular Matrix Proteome

Liliane Hobeika,[1] Michelle T. Barati,[1] Jon B. Klein,[1,2] Kenneth R. McLeish,[1,2] Michael Merchant.[1] *[1]Medicine, Univ of Louisville; [2]Dept of Veterans Affairs, Louisville, KY.*

Background: Increased glomerular extracellular matrix (ECM) is present in many glomerular diseases, eg. diabetic nephropathy and FSGS. Defining the ECM proteome by mass spectrometry (MS) offers the opportunity to determine the mechanism for increased ECM and identify disease specific markers. The optimal conditions for ECM isolation and MS analysis have not been determined. This study compared three extraction techniques in glomeruli isolated by laser capture microdissection (LCMD) from two types of tissue preparation.

Methods: Frozen (FR) and formalin-fixed paraffin embedded (FFPE) tissue from the same human kidney were cut into 10mm sections, stained with hematoxylin, glomeruli isolated by LCMD. Glomerular proteins were extracted by a) Protease MAX surfactant + boiling (MAX) or sequential decellularized with b) SDS or c) NH4OH/TritonX-100 (TX) followed by extraction of residual ECM by MAX. Proteins were trypsinized, peptides identified by MS, and data analyzed with Mascot/Sequest search strategy. ANOVA was used to determine differences in protein abundances.

Results: The total protein yield and number of proteins identified were determined in various numbers of glomeruli slices ranging 50 to 150. There was no significant increase in yield above 75 glomeruli slices. Compared to MAX (2032), extraction with SDS or TX increased the total number of proteins identified (2207 and 2246). The total number of proteins identified from FR and FFPE tissue did not differ for any of the extraction methods. More proteins were identified in residual ECM from FFPE than FR with TX (1863 vs 1713) and SDS (1826 vs 1385). By GO annotation, sequential extraction improved the abundance of ECM, as shown by identification of an increased number of, and increased total sequence coverage of, collagen isoforms. More proteins were identified in the cellular fraction from FR compared to FFPE with TX (1646 vs 1294) and SDS (1804 vs 1115).

Conclusions: Using LCMD, sequential extraction with SDS or TX, and peptide identification by MS, the glomerular ECM proteome of patients can be identified from a number of glomeruli compatible with a typical renal biopsy embedded in paraffin.

FR-PO305

BMP-7 Inhibits Renal Akt Signaling Debra F. Higgins, Catherine Godson. *School of Medicine, Conway Inst, Univ College Dublin, Dublin, Ireland.*

Background: Bone morphogenetic protein-7 (BMP-7), a member of the TGFβ-superfamily, counteracts pro-fibrotic $TGFb_1$ and protects from fibrosis in acute and chronic renal injury models.

Methods: Using the chronic renal fibrosis model, unilateral ureteral obstruction (UUO), we investigated the effect of exogenous-rhBMP-7 on signaling pathways involved in hypoxia and $TGFb_1$-induced fibrosis. Mice undergoing UUO were treated with either vehicle or rhBMP-7 (300mg/kg i.p.), kidneys were harvested on day 8 post-obstruction and analysed for markers of renal fibrosis and activation of SMAD, MAPK, and PI3K signaling.

Results: In response to UUO, SMAD1/5/8 activity was lost in vehicle-treated kidneys yet maintained in BMP-7-treated kidneys. Collagen accumulation was significantly increased in obstructed kidneys of vehicle-treated animals compared with contralateral and this response was not observed in BMP-7-treated obstructed kidneys. Immunohistochemical analysis of type I, III, and IV collagen revealed that accumulation of type I collagen was significantly impaired in BMP-7-treated obstructed kidneys. Activation of SMAD2, SMAD3, ERK, p38 and Akt signaling pathways occurred during fibrogenesis and BMP-7 significantly attenuated SMAD3 and Akt signaling in vivo. In the kidney, inner medullary collecting duct and tubular epithelial cells are responsive to BMP-7. Analysis in mouse inner medullary collecting duct (mIMCD) and human tubular epithelial (HK-2) cell lines stimulated with either $TGFb_1$ or hypoxia (1% oxygen) to induce Akt activation provided further evidence that BMP-7 could specifically inhibit PI3K / Akt signaling.

Conclusions: These data demonstrate an important mechanism by which BMP-7 orchestrates renal protection through Akt inhibition and strengthens the argument for use of Akt inhibitors as anti-fibrotic therapeutics.

Prevention of Renal Interstitial Fibrosis by Simultaneous Deletion of Bax and Bak Hee-Seong Jang,[1] Babu J. Padanilam.[1,2] *[1]Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE; [2]Internal Medicine, Section of Nephrology, Univ of Nebraska Medical Center, Omaha, NE.*

Background: Proximal tubular injury and apoptosis are key mediators of development of kidney fibrosis, a hallmark of chronic kidney disease. However, the molecular mechanism by which tubular apoptotic cell death leads to kidney fibrosis is poorly understood.

Methods: Here we tested the roles of Bax and Bak, two crucial proteins involved in intrinsic apoptotic cell death, in progression of kidney fibrosis. Mice with proximal tubule-specific Bax deletion, systemic deletion of Bak and dual deletion of Bax and Bak were subjected to unilateral ureteral obstruction (UUO).

Results: Dual deficiency of Bax and Bak inhibited tubular apoptosis and atrophy. Consistent with decreased tubular injury, dual ablation of Bax and Bak suppressed UUO-induced inflammation and kidney fibrosis with decreased tubular cell cycle arrest, expression of fibrogenic and inflammatory cytokines, and oxidative stress in the kidney. Bax or Bak deficiency was insufficient to prevent apoptosis and all other aforementioned malevolent effects, suggesting compensatory mediation by each other in the respective signaling pathways.

Conclusions: These data suggest that dual ablation of Bax and Bak in the kidney is required to prevent UUO-induced tubular apoptosis and the consequent kidney inflammation and fibrosis.

FR-PO307

Investigating the Role of Cilia in Regulating Fibrosis in the Kidney and Liver Using PKD Mouse Models Kurt Zimmerman, Cheng 'Jack' Song, Bradley K. Yoder. *Cell, Developmental, and Integrative Biology, UAB, Birmingham, AL.*

Background: Cystic kidney disorders are frequently caused by mutations in cilia associated proteins (intraflagellar transport, IFT) or ciliary signaling proteins (polycystin-1 or polycystin-2). Comorbidities commonly associated with renal cysts include biliary duct abnormalities with associated fibrosis in both tissues. In the kidney of cilia mutants, ischemia reperfusion (IR) injury greatly exacerbates the rate of cyst development; however, it is not known whether injury will similarly affect the liver and how loss of cilia affects injury induced fibrosis.

Methods: To address these questions, we are utilizing *Oak Ridge Polycystic Kidney* (ORPK) mice that have a congenital hypomorphic IFT88 mutation and conditional mutant mice where cilia are disrupted in the kidney (CaggCreER). The conditional mutant mice undergo IR injury and are analyzed to evaluate disease progression, inflammatory responses, and production of extracellular matrix (ECM) and pro-fibrotic growth factors.

Results: Our preliminary studies in the kidney indicate that IFT88 mutant mice receiving IR injury have increased ECM transcripts for *Col1a2, Col3a1,* and *fibronectin* compared to the sham operated kidney. Despite the increased ECM production, the pro-fibrotic growth factor TGF-β, which is frequently associated with fibrosis, was not significantly elevated in mutant mice. However, another TGF-β family member, inhibin β_A, was increased in the injured kidney of mutant mice suggesting a possible mechanism for ECM production. ORPK mutant mice have a noticeable liver phenotype characterized by biliary hyperplasia and, similar to the kidney, an increase in *Col3a1* and *Col1a2* transcripts. ORPK mutant mice also have increased transcript levels of the monocyte chemoattractant protein, *MCP1,* and the pro-inflammatory cytokine, *IL-1β*. Furthermore, in both mutant kidney and liver there is an increase in the number of infiltrating macrophages, which may drive fibrosis.

Conclusions: Together, our preliminary data suggest that defects in cilia formation promote fibrotic disease progression possibly through altered cytokine production and enhanced recruitment of infiltrating monocytes.

FR-PO308

Klotho Suppresses Epithelial-Mesenchymal Transition /or Transformation in Adriamycin Nephropathy Tsuneo Takenaka,[1] Tsutomu Inoue,[2] Matsuhiko Hayashi.[3] *[1]International Univ of Health and Welfare; [2]Saitama Medical Univ; [3]Keio Univ.*

Background: Klotho interacts with various proteins to alter their function. Klotho may bind to the receptor for WNT and TGFbeta, inhibiting their signals.

Methods: Experiments were performed to assess how klotho protects kidney from its injury. Adriamycin (5 mg/Kg) was injected into rats to induce nephropathy. Human recombinant klotho (K, 30 micro-g/kg/day), 4-benzyl-2-methyl-1,2,4-thiadiazolidine-3,5-dione (GSK3beta blocker, 0.2mg/kg/day, T) or vehicle (A) was administered. Rats which were untreated with Adriamycin were used as control (U). Animals were killed 8 weeks later. Renal expressions of Wnt1, GSK3beta, TGFbeta1, Twist and collagen I were assessed with RT-PCR against GAPDH. Western blot was used for p-GSK3beta and beta-action.

Results: Adriamycin increased albuminuria, renal expression of Wnt1, p-GSK3beta, TGF, Twist and collagen 1 in comparison to the control. Klotho and T suppressed adriamycin-induced albuminuria and the phosphorylation of GSK3beta with sustained elevations of Wnt1, supporting that klotho inhibit Wnt signaling without changes in Wnt level. While klotho and T reduced TGFbeta, klotho preferentially ameliorated Twist and collagen I in comparison to T.

	U	A	K	T

Conclusions: Our data indicate that WNT is involved in pathogenesis of Adriamycin nephropathy. Furthermore, the present findings demonstrated that the inhibition of WNT contributed to glomerular protective actions of klotho. Finally, our results suggest that klotho suppresses Epithelial-Mesenchymal Transition /or Transformation by inhibiting TGFbeta as well as WNT signaling.

The Molecular Mechanism of miR-382 in the Pathogenesis of Renal Tubulointerstitial Fibrosis Yi Fang,[1,2] Ting Xie,[1] Hui Zhang,[1] Sheng Wu.[1] *[1]Nephrology, Zhongshan Hospital Fudan Univ, China; [2]Shanghai Key Laboratory of Kidney Diseases and Blood Purification.*

Background: To investigate the roles of microRNA-382 (miR-382) in the pathogenesis of renal tubulointerstitial fibrosis.

Methods: Human kidney epithelial (HK2) cells that transfected with a miR-382 inhibitor (antagomiR-382) was used to exam the effect of miR-382 abundance on cell polarity, as well as to test the complementary relationship between miR-382 and its predicted target gene, heat shock 60kDa protein 1(HSPD1), which was further verified by site-directed mutagenesis. We also examined the in vivo role of miR-382 in the development of renal interstitial fibrosis, in a mouse unilateral ureteral obstruction (UUO) model. Locked nucleic acid-modified anti-miR-382 was intravenous delivered via tail vein less than 30mins prior to UUO, and repeated the dosage 24 hours after the surgery. For clinical verification, renal biopsy specimens from 12 IgA nephropathy (IgAN) patients were collected, 6 with moderate to severe tubulointerstitial fibrosis (TIF) and 6 with no TIF. The relative abundance of miR-382 and HSPD1protein was analyzed using in situ hybridization and immunohistochemistry.

Results: HSPD1 was confirmed to be a new, direct target gene of miR-382 by in vitro transfect technique and mutation experiments. The development of epithelial transition or renal interstitial fibrosis was accompanied with up-regulated abundance of miR-382. Down-regulation of miR-382 was associated with significant attenuation of interstitial fibrosis, but increase protein expression of HSPD1and thioredoxin, both in the obstructed mouse kidneys and renal biopsy specimen from IgAN patients.

Conclusions: MiR-382, a profibrotic microRNA, is up-regulated with the development of renal interstitial fibrosis in humans and in mice. The down-regulation of HSPD1 and the decreased ability of anti-oxidative stress are secondary to the increased abundance of miR-382.

Assessing the Role of Gremlin-1 on Renal Fibrosis In Vitro Marcela Herrera, Lihuan Liang, Asha Seth, Carol Patricia Moreno Quinn. *Cardiovascular & Metabolic Diseases, Medimmune, Cambridge, United Kingdom.*

Background: Bone Morphogenic Proteins (BMPs) signal through SMAD1/5/7 to upregulate genes that antagonize fibrosis. The endogenous antagonist gremlin-1 binds and antagonizes extracellular BMPs, inhibiting their anti-fibrotic effects. Gremlin-1 is up-regulated in the proximal tubule (PT) of DN patients. We hypothesized that Gremlin-1 participates in the development of renal fibrosis by inducing a pro-fibrotic phenotype in proximal tubules and renal interstitial fibroblasts.

Methods: To test this hypothesis we used HK-2 (human PT cell line) and NRK49F (rat renal fibroblasts) cell lines where the pro-fibrotic phenotype was induced by Transforming Growth Factor b1 (TGFb: 2.5 ng/mL, 72 hrs). Gremlin-1 secretion and protein expression was measured by Western blotting and gene expression by qPCR.

Results: In PT cells, TGFb stimulated gremlin-1 protein secretion by 2.3 fold (from 57 ± 5 to 134 ± 2 arbitrary units; $p<0.05$), increased fibronectin-1 (FN1, an extracellular matrix component) by 50% ($p<0.05$) and reduced expression of e-cadherin (e-CAD, an epithelial marker) by 95% ($p<0.05$). All changes also occurred at the mRNA level. Gremlin-1 siRNA significantly reduced gremlin-1 mRNA expression and efficiently blocked the TGFb-induced Gremlin-1 release by 100%. However, Gremlin-1 knockdown did not prevent the pro-fibrotic changes of TGFb. In contrast to PT cells, TGFb did not induce gremlin-1 secretion in renal fibroblasts. TGFb increased FN1 and a-smooth muscle actin (aSMA, marker of fibroblast activation) in a dose-dependent manner. Addition of gremlin-1 (mimicking the in vivo setting) did not exacerbate fibrosis at any dose of TGFb. Addition of recombinant BMP2 was not sufficient to prevent TGFb-induced fibrosis in either cell type. Recombinant BMP2 alone (1 nM) increased SMAD5 phosphorylation and the expression of ID1 (a marker of BMP signalling) at 1 and 24 hrs post treatment. The stimulatory effect of BMP2 was blocked by pre-treatment with recombinant Gremlin-1 (2 nM). These data confirm intact BMP2/gremlin-1 signalling in both cell types.

Conclusions: Our data does not support the participation of gremlin-1 in TGFb-dependent renal fibrosis in vitro.

FR-PO311

Vitamin (Vit) D Repletion Ameliorates Muscle Wasting and Muscle Fibrosis in Mice with Chronic Kidney Disease Wei Ding, Wai W. Cheung, Mary Christine Esparza, Ping Zhou, Richard L. Lieber, Robert H. Mak. *Pediatric Nephrology, Univ of California, San Diego, La Jolla, CA.*

Background: Cachexia presenting as muscle wasting and weakness is prevalent in CKD patients and may impact their quality of life. We investigated the effects of vitamin D repletion in a mouse model of CKD-associated cachexia and vitamin D deficiency.

Methods: CKD in c57BL/6 mice were induced by 5/6 nephrectomy. CKD and sham mice were treated with 25VitD (25 mg/kg/day), 1,25VitD (40 ng/kg/day) or vehicle (V) for 6 weeks via a subcutaneous osmotic pump. CKD+V mice were fed *ad libitum* while other groups of mice were pair-fed to CKD+V mice. Parameters of energy homeostasis, skeletal muscle histomorphometry and *in vivo* muscle function were measured. The expression of key molecules implicated in myogenesis and fibrosis pathway was assessed using a focused PCR array.

Results: Serum 25VitD and 1,25VitD levels were significantly lower in CKD than sham mice ($p<0.01$) and was increased, within the physiological range, by 25VitD and 1,25VitD repletion in CKD mice. CKD mice exhibited reduced weight gain, increased energy expenditure, loss of lean mass and decreased muscle function (measured by grip strength and rotarod tests) than sham mice ($p<0.01$). Increased energy expenditure in CKD mice was associated with upregulation of uncoupling proteins (UCPs) in skeletal muscle and adipose tissues. Soleus muscle fiber area and *in vivo* muscle function was significantly reduced in CKD mice than sham controls ($p<0.05$). Skeletal muscle fibrosis, a major pathological hallmark of myopathies, is evident in CKD mice. Soleus collage content was significantly increased in CKD than sham mice ($p<0.01$). Gene expression of myogenesis and fibrotic pathways were increased in CKD than sham mice ($p<0.01$). Perturbations in weight gain, energy expenditure, UCPs, loss of lean mass, muscle function tests, soleus muscle fiber area, soleus collagen content as well as aberrant gene expression involved in myogenesis and muscle fibrotic pathway in CKD mice were normalized by 25VitD but only partially attenuated by 1,25VitD repletion.

Conclusions: 25VitD and 1,25VitD repletion have differential effects on muscle wasting and muscle fibrosis in CKD mice.

FR-PO312

The Effect of Cell Culture Surface Coating on Glomerular Endothelial Cell Phenotype Kamilla Pajecka,[1,2] Troels Krarup Hansen,[1] Julie Williams.[2] *[1]Endocrinology and Internal Medicine, Aarhus Univ Hospital, Aarhus, Denmark; [2]Diabetes Complications Biology and Pharmacology, Novo Nordisk A/S, Maaloev, Denmark.*

Background: Glomerular endothelial cells (GEnCs), podocytes and the glomerular basement membrane are the major constituents of the glomerular filtration barrier (GFB), which is fundamentally impaired in diabetic nephropathy (DN). The DN drug-candidate screening process involves in vitro use of the GFB components either singly or in combination. The aim of this study was to determine the effect of commercially available extracellular matrix (ECM) components on GEnC characteristics.

Methods: Primary human GEnCs were from Cell Systems. Cell culture surface coating included: collagen IV (COLIV), laminin521 (hLN521), laminin111 (hLN111) or Attachment Factor (AF; Cell System's proprietary GEnC coating). Cell adhesion was monitored by the xCELLligence system. The mRNA expression was assessed by qPCR. The localization of zonula occludens (ZO)-1 protein was studied by fluorescent immunolabeling.

Results: Coating with AF or COLIV increased the cell index (CI) of GEnCs in the cell adhesion phase (0-6h) but not in the spreading and proliferation phase (6-72h). Coating with hLN521 displayed a continuous increase in CI over 72h. On the contrary, hLN111 caused a significant decrease in CI over 72h. Cells grown on AF or COLIV showed similar mRNA expression pattern of chosen genes as cells grown on uncoated surfaces. By contrast, coating with hLN521 decreased the expression of COL4A1, COL4A2, MMP2 [all 2-fold] and TGFB1 [1.5-fold] as compared to no coating. Likewise, ITGA1, ITGA2, ITGAV, ICAM1, NOX4 were decreased with hLN521 in a dose-dependent manner. Expression of LAMA5, COL4A5, ITGA3 and NOS3 were unchanged in all groups. Tight junction formation was assessed by ZO-1 immunostaining. Laminin521, contrary to other ECM coatings, stimulated tight junction formation in GEnCs.

Conclusions: Usage of AF or COLIV in GEnC culture shows little advantage. DN-associated hLN111 is a poor attachment substrate resulting in GEnC loss. This is in contrast to the more physiologically relevant hLN521 which promotes cell adhesion, spreading, proliferation and tight junction formation.

Development of an Ex Vivo Model to Elucidate the Matrix Turnover Profile in Renal Interstitial Fibrosis Signe Holm Nielsen,[1,2] Zsolt Soma Karpati,[1] Daniel Guldager Kring Rasmussen,[1,3] Morten Asser Karsdal,[1] Federica Genovese.[1] *[1]Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; [2]System Biology, Denmark Technology Univ, Kgs. Lyngby, Denmark; [3]Southern Denmark Univ, Odense, Denmark.*

Background: Renal interstitial fibrosis is characterized by dysregulated extracellular matrix (ECM) turnover and protease activity. ECM protein fragments generated by protease cleavage can be measured by specific ELISAs, providing a protein fingerprint of the disease. The aim of this study was to set up an *ex-vivo* model for renal interstitial fibrosis in order to investigate the ECM turnover profile in the fibrotic kidney.

Methods: 14 male 12 weeks old Sprague-Dawley rats underwent Unilateral Ureteral Obstruction (UUO) surgery by ligation of the right ureter. The left kidney (contralateral) was used as internal control. 6 rats were sham-operated and used as control group. Rats were terminated 2 weeks after the surgery, when advanced fibrosis is known to be present. The kidneys were excised and precision-cut tissue slices (PCTS) were cultured for 5 days in serum free medium. Markers of collagen type I formation (P1NP), collagen type III degradation (C3M) and α-smooth muscle actin (α-SMA) were measured in the PCTS supernatants. The extent of tubulointerstitial fibrosis was evaluated by histology.

Results: P1NP, C3M and α-SMA were significantly increased in supernatants of tissue slices from the UUO ligated kidneys compared to the contralateral kidneys ($p<0.001$) and to sham operated animals ($p<0.0001$). However the markers had a high inter-individual variability in the UUO group. When comparing the levels of the markers from the UUO kidney to those from the corresponding contralateral kidney, animals with pronounced differences were those presenting advanced fibrosis in histology.

Conclusions: The UUO PCTS *ex vivo* model provides a valuable translational tool for investigating the ECM remodeling associated with renal interstitial fibrosis. Since the protein fingerprint technology allows the measurement of the markers measured in the supernatants also in circulation and in urine, these markers have the potential to accurately and non-invasively describe the tissue remodeling during fibrosis.

FR-PO314

Collagen Degradation Profile in a Nephrotoxic Nephritis Model Signe Holm Nielsen,[1,2] Daniel Guldager Kring Rasmussen,[1,3] Gabriela Campanholle,[4] Robert V. Martinez,[4] Morten Asser Karsdal,[1] Federica Genovese.[1] *[1]Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; [2]System Biology, Denmark Technology Univ, Kgs. Lyngby, Denmark; [3]Southern Denmark Univ, Herlev, Denmark; [4]Inflammation and Immunology, WRD, Pfizer Inc., Cambridge, MA.*

Background: The nephrotoxic nephritis (NTN) mouse model is characterized by a rapid onset of nephritis, followed by tissue destruction and progression to renal scarring. We aimed at identifying markers for early disease onset that were directly linked to the events of scar formation in the kidney.

Methods: Neo-epitope degradation fragments of collagen type I, III and IV generated by MMP cleavage were measured by specific ELISAs (namely C1M, C3M and C4M) in urine of NTN and healthy mice terminated at 7 and 21 days after injury (NTN: n=21, Controls: n=6). Urinary albumin/creatinine (ACR), urinary proteinuria, plasma creatinine and blood urea nitrogen (BUN) were measured as markers of renal function. Interstitial fibrosis and glomerulosclerosis were evaluated by histology and quantification of α-SMA and collagen type I in immunohistochemistry.

Results: While C1M levels in urine were not different between NTN mice and controls, C3M levels were elevated in NTN rats at 7 days ($p<0.05$) and decreased to levels close to the controls at 21 days. This elevation was also reflected in proteinuria, peaking at 7 days, but not in BUN and plasma creatinine. C4M levels were elevated at 21 days and not at 7 days ($p<0.01$), and correlated with the extent of interstitial fibrosis.

Conclusions: Different degradation markers of the most abundant proteins in the renal interstitial matrix (collagen type I and III) and in the tubular basement membrane and mesangium (collagen type IV - a1 chain) presented a different longitudinal release in urine. While degradation of collagen type III is an early event in this model, maybe reflecting the early inflammatory state, degradation of collagen type IV appears later, when the formation of the scar is evident in histology. These markers could potentially be used to non-invasively describe the fibrotic events in the kidney in experimental models and, since the targeted epitopes are conserved in human, they could be applied in clinical settings.

FR-PO315

Evidence of Podocyte Protrusions into the Basement Membrane in Glomerular Disease Sophie C. Collinson,[1] Michael J. Randles,[1,2] Mira Krendel,[3] Eva Koenigshausen,[4] Lorenz Sellin,[4] Ian Roberts,[5] Jeffrey H. Miner,[6] Rachel Lennon.[1,2] *[1]Inst of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester, United Kingdom; [2]Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, Univ of Manchester, United Kingdom; [3]Dept of Cell and Developmental Biology, SUNY Upstate Medical Univ, Syracuse, NY; [4]Dept of Nephrology, Heinrich Heine Univ, Duesseldorf, Germany; [5]Dept of Cellular Pathology, John Radcliffe Hospital, Oxford, United Kingdom; [6]Renal Div, Washington Univ School of Medicine, St. Louis, MO.*

Background: Glomerular disease is a leading cause of kidney failure. Podocyte foot process effacement and glomerular basement membrane (GBM) disruption are frequent abnormalities regardless of the underlying molecular etiology. Standard electron microscopy techniques provide 2D information and 3D ultrastructural relationships are poorly understood. We hypothesized that creation of detailed 3D models of the glomerulus would identify novel pathological features.

Methods: Serial block face-scanning electron microscopy was performed on a series of genetic mouse models of glomerular disease with established albuminuria. 3D reconstructions of glomeruli were created using IMOD 4.7.11.

Results: Sub-podocyte expansions of the GBM were dominant features in *Glepp1-/-*, *Myo1e-/-* and *Col4a3-/-* mice and overall GBM thickness was significantly different to matched wild-type (WT) controls ($p<0.0001$). There was a corresponding reduction in podocyte foot process number in each of the models ($p<0.0001$). Furthermore we identified novel podocyte protrusions into the GBM in all mutant mice and these were not present in WT controls. There was no evidence of endothelial or mesangial cell protrusions into the GBM and no correlation between GBM thickness and the site of podocyte protrusions.

Conclusions: 3D ultrastructural imaging revealed expected GBM abnormalities in addition to podocyte protrusions, resembling invadasomes, in the GBM. This novel finding provides new insight into disease mechanisms and suggests that a common matrix-adhesion pathway is activated regardless of the primary molecular insult.

Multi-Clonal Population of Cells of Renin Lineage (CoRL) Transdifferentiate into Podocytes and PECs in Experimental FSGS Natalya V. Kaverina,[1] Diana G. Eng,[1] Jeffrey W. Pippin,[1] Michael E. Rusiniak,[2] Kenneth W. Gross,[2] Stuart J. Shankland.[1] *[1]Devision of Nephrology, Univ of Washington, Seattle, WA; [2]Dept of Molecular and Cellular Biology, Roswell Park Cancer Inst, Buffalo, NY.*

Background: Focal segmental glomerulosclerosis (FSGS) is secondary to podocyte injury and loss. Because adult podocytes cannot proliferate, their replacement by progenitors is critical for their repair and regeneration in disease.Here we explored whether single or multiple clones of cells of renin lineage (CoRL) serve as a local progenitor source to replace reduced podocytes in experimental FSGS.

Methods: Experimental FSGS was induced following abrupt podocyte depletion by administration of a cytotoxic anti-podocyte antibody in two confetti mouse reporters. First, to confirm adult podocyte regeneration following abrupt depletion, podocytes were genetically fate-mapped in adult NPHSP2^{Cre}/Confetti$^{TG/WT}$ reporter mice with experimental FSGS. Second, to prove that adult podocyte regeneration by CoRL was multi-clonal, CoRL were fate mapped in RenCre / Confetti$^{TG/WT}$ reporter mice with experimental FSGS.

Results: FSGS in NPHSP2^{Cre}/Confetti$^{TG/WT}$ mice was characterized by marked podocyte depletion (45% decrease) on d7. A multi-clonal repopulation of podocytes resulted in an increase in their overall number to 77% of normal by d28. No podocyte proliferation was detected by BrdU staining. In RenCre/Confetti$^{TG/WT}$ mice, a multi-clonal expansion of 4 color-labeled CoRL (GFP, RFP, CFP, YFP) was detected in glomeruli at FSGS d28. A subset of all clonal reporters co-expressed 5 podocyte markers (podocin, synaptopodin, p57, WT-1, nephrin). CoRL were also observed along Bowman's capsule and co-expressed PEC markers (PAX2, claudin-1). BrdU staining did not co-localize with CoRL reporters.

Conclusions: Following an abrupt depletion of adult podocytes in experimental FSGS, their number was increased in the absence of podocyte proliferation. Regeneration of adult podocytes was likely in part due to multiple clones of CoRL serving as local progenitors.

Macula Densa-Derived Factors Control Glomerular Cell Remodeling Anne Riquier-brison, Donna Ralph, Jasmine Ann Arevalo Castillejos, Janos Peti-Peterdi. *Physiology and Biophysics, Univ of Southern California, Los Angeles, CA.*

Background: Macula densa (MD) cells are strategically positioned at the vascular entrance of the glomerulus and control renal hemodynamics and renin. In this study, we addressed a novel, non-traditional role of MD cells regulating glomerular cell plasticity/remodeling by mesenchymal progenitor cells.

Methods: For genetic cell fate tracking, tamoxifen-induced NG2CreERT2-Tomato mice were fed either a control or salt-deficient + ACE inhibition (SD+ACEi) diet, for 2 weeks to achieve strong MD stimulation.

Results: We observed a 5-fold increase in renal interstitial density of NG2-derived (NG2+) cells (5.9±1.1 cells per field in control, 30.2±4.5 in SD+ACEi), and the homing of NG2+ cells to the mesangium under the MD and into the glomerulus. This effect was blunted by the selective COX-2 inhibitor SC58236 (COX-2i) or the nNOS inhibitor 7-NI (13±2.2 cells per field with COX-2i and 11.6±1.7 with 7-NI). Immunofluorescence (IF) of Claudin-1 showed a 4-fold increase in the number of NG2+ cells in the glomerular parietal layer (0.5±0.2 cells per glomerulus in control, 2.0±0.4 in SD+ACEi). Podocin IF identified a few NG2+ podocytes. NG2+ cell homing was blunted by COX-2i and 7-NI (1.2±0.3 cells per glom with COX-2i, 0.8±0.3 with 7-NI). Co-localization of endogenous NG2-Tomato fluorescence with IF of renin revealed an increase in the proportion of NG2+ renin-expressing cells from 22.0%±6.6 to 70.6%±7.4 after SD+ACEi, inhibited by COX-2i. Similarly, the density of proliferating cells expressing Ki67 increased after treatment (2.0±0.5 Ki67+ cells per field in control, 11.3±2.8 in SD+ACEi, $p<0.05$), in particular in the vicinity of the juxtaglomerular area, inhibited by COX-2i (5.6±1.0) and 7-NI (2.7±0.3).

Conclusions: Our results suggest that NG2+ pericytes may be an important progenitor cell population in the kidney. In response to MD-derived (from COX-2 and nNOS) paracrine factors, NG2+ cells from the renal interstitium proliferate and migrate towards the MD along the afferent arteriole and via the vascular pole into the glomerular epithelium and mesangium. In conclusion, MD cells play new important roles in the maintenance and remodeling of the glomerulus.

FR-PO318

A Novel Method for Assessing Podocyte Depletion in Whole Glomeruli Victor G. Puelles,[1] James William Van der Wolde,[1] Luise A. Cullen-McEwen,[1] Keith E. Schulze,[2] Jonathan Guy Bensley,[1] Kieran M. Short,[1] Georgina Caruana,[1] Stacey Hokke,[1] Stephen D. Firth,[2] Ian S. Harper,[2] David J. Nikolic-Paterson,[3] John F. Bertram.[1] *[1]Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia; [2]Monash Micro Imaging, Monash Univ, Melbourne, Victoria, Australia; [3]Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia.*

Background: Podocyte depletion plays a major role in the development and progression of glomerulosclerosis. Given that glomerulosclerosis is often focal, affecting some but not all glomeruli, our aim was to develop a rapid, accurate and precise method for quantifying podocyte depletion in whole glomeruli.

Methods: Pod^{Cre}iDTR mice, in which expression of the human diphtheria toxin (DT) receptor is driven by the podocin promoter, and iDTR mice (controls) were injected with DT (100ng/kg). Tissue was collected at day 35 for podocyte analysis (n=3 mice per group). 800mm thick kidney slices were immunostained with antibodies against p57 and synaptopodin. Slices were cleared with benzyl alcohol, benzyl benzoate (BABB). An SP8 confocal microscope (Leica, Germany) fitted with a BABB objective (NA: 0.95; working distance: 2mm) was used. Total podocyte number was obtained by manual counting and using a semi-automated system (Imaris, Bitplane) in 88 whole glomeruli - 38 from iDTR mice and 50 from Pod^{Cre}iDTR mice.

Results: In iDTR mice (controls), total podocyte number per glomerulus was almost identical between manual counts (66.61±11.92) and Imaris (65.47±9.26; P=0.65). In Pod^{Cre}iDTR mice, total podocyte number was also similar between manual counts (52.96±11.74) and Imaris (53.51±11.35; P=0.81). With both methods, podocyte counts were obtained in less than 2 minutes per glomerulus, a significant time reduction compared to existing methods. Imaris also facilitates the estimation of podocyte and glomerular volumes for a complete assessment of podocyte morphology.

Conclusions: This is the first method to combine immunofluorescence, BABB-clearing and confocal microscopy to count podocytes in whole glomeruli. The method is accurate, precise and rapid, and provides a novel approach for podocyte morphometrics in settings where sufficient tissue is available for analysis.

FR-PO319

Characterization of Heterogeneous Podocyte Biomechanics Using Atomic Force Microscopy Evren U. Azeloglu,[1] Jia-Jye Lee,[2] Kevin D. Costa.[2] *[1]Pharmacology and Systems Therapeutics, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Cardiology (Medicine), Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Biomechanical signals play a key role in glomerular physiology, where pathological changes in blood pressure can significantly affect podocyte morphology and function. While there has been a great focus on mechanobiological signaling in podocytes, their spatial biomechanical properties have been largely overlooked due to a lack of *in*

vitro systems that can spatially segment subcellular components. We have developed a novel microengineered culture system that mechanically induces arborization of podocytes such that they form functional peripheral shape-induced processes that locally express slit diaphragm markers and bundled actin fibers *in vitro*. We then used atomic force microscope elastography to quantitatively characterize the subcellular biomechanical properties of isolated human podocytes.

Methods: Glass coverslips were micropatterned with interconnected channels using standard photolithography techniques. Immortalized human podocytes were plated on micropatterned slides, and cultured at 37ºC for five days. They were then transferred to an Asylum Bioscope AFM and probed with 2 mm deep indentations at a rate of 1 mm/sec. Depth-dependent pointwise apparent elastic modulus was computed at each indentation point to create a 3-D elastography map of cellular biomechanics.

Results: Live-cell imaging showed dynamic cycling of f-actin in peripheral shape-induced processes of micropatterned podocytes. These cells exhibited heterogeneous depth-dependent biomechanical properties where processes were significantly stiffer than the central cell body. Increase in stiffness correlated with presence of crosslinked actin bundles.

Conclusions: We saw significant increase in stiffness of peripheral processes in podocytes, which reaffirm the key structural role of the interdigitating foot processes in maintenance of the glomerular filtration barrier. Our microengineered culture system provides a new means to rapidly test the micromechanics of podocytes with high spatial resolution in a physiologically relevant *in vitro* setting.

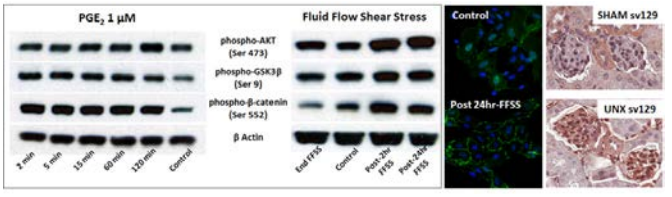
Identification and Validation of Fluid Flow Shear Stress (FFSS)-Induced Changes in Podocyte Signaling Pathways Using Bioinformatic Tools

Tarak Srivastava,[1] Hongying Dai,[1] Ashraf El-Meanawy,[2] Ellen T. McCarthy,[3] Virginia J. Savin,[4] Ram Sharma,[4] Mukut Sharma.[4] *[1]Nephrology, The Children's Mercy Hospital, Kansas City, MO; [2]Nephrology, Medical College of Wisconsin, Milwaukee, WI; [3]Kidney Inst, Univ of Kansas Medical Center, Kansas City, KS; [4]Renal Research Laboratory, Kansas City VA Medical Center, Kansas City, MO.*

Background: The flow of filtrate through Bowman's space generates FFSS over podocytes. Adaptive hyperfiltration is characterized by increased single nephron GFR (SNGFR), capillary pressure (P_{GC}) and glomerular hypertrophy. The mechanism of podocyte injury from hyperfiltration-induced FFSS is not known.

Methods: We performed microarray analysis (Affymetrix GeneChip Mouse Exon 1.0 ST Array) on immortalized podocytes without FFSS (Control), immediately after FFSS (End-FFSS), 2 hours (post-2hr FFSS), and at 24 hours (post-24hr FFSS) after cessation of FFSS at 2 dynes/cm^2 for 2 hr. Mouse exon 1.0 ST Array has ~4 probes/ exon and ~40 probes/ gene. Data from the microarray were log transformed, normalized and filtered to generate a set of 17,494 genes. Genes that were significant at $p<0.01$ were analyzed using Ingenuity Pathway Analysis (IPA) and Enrichr Program to identify key pathways.

Results: IPA showed Akt, COX-2, and AMPK (at End-FFSS); TGF-β (at post-2hr FFSS); and p38MAPK, ERK1/2 (at post-24hr FFSS) in the main network. Enrichr Kinase Enrichment Analysis showed GSK3β, ERK1/2 in all three treatment groups compared with the control group. ChIP-x Enrichment Analysis identified transcription factor β-catenin. Western blotting, fluorescence microscopy and immunocytochemistry were used to validate changes in these signaling molecules.



Conclusions: Increased FFSS affects pathways that mediate podocyte survival and inflammation, and provide targets to address the mechanism of hyperfiltration-mediated glomerular injury.

FR-PO321

A Podocyte-Based Screening Assay Identifies Paullone-Derivatives as Novel Podocyte Protective Agents

Ha won Lee, Samia Khan, Mohd Hafeez Faridi, Terese D. Geraghty, Mehmet M. Altintas, Jochen Reiser, Vineet Gupta. *Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: Podocyte injury and loss is an early hallmark in the pathogenesis of a variety of glomerular diseases. Therefore, podocytes are an excellent cellular target for the development of kidney directed therapeutics. We recently described a novel cell-based high content screening (HCS) assay for quantifying podocyte damage in vitro. Here, we describe utilization of this HCS assay to identify a family of novel small molecules that significantly protect podocytes from injury.

Methods: We utilized cultured murine podocytes in an HCS assay using 96-well imaging plates. Phenotypic changes with podocyte damaging agent puromycin aminoglycoside (PAN) were analyzed and quantified using automated methods using thousands of podocytes per condition. Identified hits were confirmed and a number of biochemical and cell biological assays were used to validate the findings.

Results: We identified a family of small molecules, paullones, as highly potent agents that protected podocytes from damage. Kenpaullone and three other paullones (paullone, 1-azakenpaullone, and alsterpaullone) showed dose-dependent protection of podocytes from PAN-damage induced loss in F-actin fibers. Among the four paullones identified, alsterpaullone showed the highest level of protection. At a molecular level, alsterpaullone reduced the elevation in the expression of *Desmin*, a podocyte damage marker, and inhibited PAN-induced podocyte migration. While PAN treatment reduced AKT phosphorylation in podocytes, alsterpaullone maintained the levels of phosphorylated AKT in podocytes.

Conclusions: Employment of our newly described podocyte-based screening assay results in the discovery of podocyte-directed therapeutics for treating a number of glomerular diseases. Paullones represent a family of small molecules that show podocyte protection from damage. We also describe a proposed molecular mechanism for the efficacy of these novel agents. We hope that these methodologies will lead to the development of novel types of specific kidney protective drugs.

FR-PO322

Novel Podocyte Quantification Assay to Ascertain Patient Serum Toxicity

Elena Torban,[1] Nadezda Kachurina,[1] Chen-Fang Chung,[1] Sima Babayeva,[1] Nada Alachkar,[2] Thomas Kitzler.[1] *[1]Dept of Medicine, McGill Univ-McGill Univ Health Center, Montreal, QC, Canada; [2]Div of Nephrology, The Johns Hopkins Univ School of Medicine, Baltimore, MD.*

Background: Focal segmental glomerulosclerosis (FSGS) is a glomerular kidney disease that affects the podocytes and progresses to renal failure within 5-7 years, requiring dialysis or renal transplantation. In > 50% of patients, the disease is idiopathic and may recur post-transplant suggesting the presence of a pathogenic toxic factor/s circulating in the blood. The identity of this factor and the pathogenic mechanisms remain enigmatic. Recent *in vitro* studies from our lab showed that plasma from recurrent FSGS patients disturbs the human podocyte cytoskeleton and focal adhesion complexes (FACs). We developed a novel unbiased assay to quantify the toxic effects of patient plasma and nephrotoxic drugs on cultured human podocytes and to identify strategies that block serum toxicity.

Methods: Cultured human differentiated podocytes are exposed to adriamycin, recombinant TNFa or human sera from patients with various forms of FSGS. FACs are visualized with anti-vinculin antibody, and cell images are analyzed to define the number of FACs/1000mm2 cell area. We analyzed sera from 12 patients: 2 with idiopathic, 4 recurrent FSGS, 4 non-recurrent FSGS and 2 de novo FSGS.

Results: Both adriamycin and recombinant TNFa disrupt podocyte actin cytoskeleton and FACs in a dose-dependent manner. Comparing to healthy control, sera from patients with idFSGS (no known mutations identified), rFSGS and de novo FSGS post-transplant drastically reduces FACs number, yet sera from nrFSGS post-transplant does not statistically affect FACs. In ~ 60% of the patients with serum toxicity, these effects on podocytes can be averted by TNFa pathway blockade.

Conclusions: Our in vitro podocyte assay provides, for the first time, means to reliably identify those patients with idiopathic FSGS who are at high risk of recurrence post-transplant. It may also identify FSGS patients who may be candidates for anti-TNFα therapy that could prevent progressive glomerular injury.

Agalsidase Treatment Clears Gb3 from a Podocyte Model of Fabry Disease

Linda Blomberg,[1] Fabian Braun,[1] Markus M. Rinschen,[1] Max Liebau,[2] Susanne Brodesser,[3] Bernhard Schermer,[1,3] Thomas Benzing,[1,3] Christine E. Kurschat.[1,3] *[1]Dept II for Internal Medicine, Univ Hospital Cologne, Cologne, NRW, Germany; [2]Dept of Pediatrics, Univ Hospital Cologne, Cologne, NRW, Germany; [3]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, Univ of Cologne, Cologne, NRW, Germany.*

Background: In Fabry disease the deficiency of the enzyme α-galactosidase A leads to an accumulation of globotriaosylceramide (Gb3).An enzyme replacement therapy with agalsidase alfa (Replagal®) or beta (Fabrazyme®) is licensed since 2001. The establishment of an α-galactosidase A-deficient human podocyte cell line has already been published by our group. These podocytes accumulate Gb3, exhibit dysregulated AKT and mTOR signaling and dysregulated autophagy. We analyzed changes in cellular signal transduction in α-galactosidase A-deficient podocytes treated with agalsidase alfa to further investigate the molecular mechanisms underlying podocyte damage.

Methods: For seven days, α-galactosidase A-deficient podocytes were treated with 250 nM agalsidase alfa. Cells were grown on collagen-coated coverslips, fixed with PFA and processed according to standard protocols for immunofluorescence. For mass spectrometry and immunoblot detection, cell lysates were used.

Results: Compared to control cells, α-galactosidase A-deficient podocytes showed massive Gb3 accumulation in immunofluorescence and mass spectrometry analysis. The Gb3 content in Fabry podocytes was significantly reduced after treatment with agalsidase alfa. Interestingly, the strong Gb3 clearance dysregulation of the AKT and mTOR signaling pathways remained unchanged upon treatment with 250 nM agalsidase alfa for 7 days. In both treated and untreated Fabry podocytes autophagic activity was elevated.

Conclusions: A significant reduction of accumulated Gb3 in Fabry podocytes was shown with enzyme replacement therapy. Surprisingly, no significant changes in agalsidase-treated podocytes were detected for key enzymes of autophagy regulation under these conditions. In ongoing studies we will use mass spectrometry and different treatment conditions to focus on identifying additional proteins modified by Gb3 accumulation.

Loss of Robo2 in Podocytes Protects Adult Mice from Acute Glomerular Injury Anna Pisarek-Horowitz, Xueping Fan, Hila Milo Rasouly, Stefanie Chan, Hui Chen, Ramon G. Bonegio, Joel M. Henderson, David J. Salant, Weining Lu. *Renal, Boston Univ Medical Center, Boston, MA.*

Background: SLIT2 and its receptor ROBO2 play an important role during kidney development. We have recently found that ROBO2 is expressed in developing glomerular podocytes. However, the role of ROBO2 in the adult mouse kidney, particularly under acute glomerular injury conditions, is not clear.

Methods: To test the hypothesis that loss of *Robo2* in glomerular podocytes affects the outcome of acute glomerular injury, we applied two *in vivo* acute glomerular injury models induced by nephrotoxic serum (NTS) injection and protamine sulfate (PS) perfusion, in *Robo*2 podocyte specific knockout mice (*Robo2* cKO) and wild type controls. Kidney glomerular ultrastructure was analyzed by scanning and transmission electron microscopy before and after injury. Podocyte foot process width and slit diaphragm density were measured to quantify the severity of the glomerular injury. Urine albumin to creatinine ratio was measured in the NTS model. Podocyte specific gene expression was analyzed using TaqMan real time PCR for mRNA and Western blot for protein levels.

Results: *Robo2* podocyte specific knockout mice developed less proteinuria after the NTS injury with lower urine albumin/creatinine ratio as compared to the wild type controls. Electron microscopy showed that *Robo2* cKO mice have milder foot process effacement and less defects in the slit diaphragm induced by either NTS or PS injury. TaqMan and Western blot analyses revealed that nephrin, a crucial transmembrane component of the podocyte slit-diaphragm, was significantly up-regulated at both mRNA and protein levels in the *Robo2* cKO mice before NTS injury and at the late stage of heterologous phase after the NTS injury. In addition, the mRNA levels of *Robo2* and *Slit2* in the wild type kidneys were also upregulated after the NTS injury.

Conclusions: SLIT2-ROBO2 signaling pathway plays an important role in the adult mouse kidney podocytes and loss of *Robo2* protects mice from acute glomerular injury. Our findings suggest that SLIT2-ROBO2 signaling might also have a negative impact on nephrin expression during podocyte injury and be a potential therapeutic target.

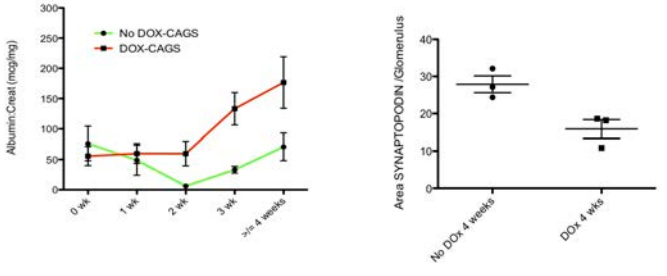
FR-PO325

Inducible Knockdown of Shroom3 Induces Proteinuria with Podocyte Dedifferentiation Madhav C. Menon, Chengguo Wei, Karen Lok Yee Keung, Ilana Greene, Weijia Zhang, John C. He, Barbara T. Murphy. *Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Intronic loci in Shroom3 have been associated with CKD and CAN. A role for Shroom3 in the podocyte cytoskeleton has been shown. However Shroom3 knockout mice die neonatally with neural tube defects and detailed renal phenotypes are unknown. Here we report our findings from Doxycycline (DOX) inducible, shRNA-mediated shroom3 knockdown mice.

Methods: In these mice Shroom3-specific shRNA expression was induced upon DOX-feeding, with RTTA expression in all cells driven by CAGS-promoter. Six-wk old mice were fed DOX-feed/water. Non-DOX fed littermates were controls (n=6 each). At 4- and 8-weeks, renal tissue was obtained for histology. Twenty-five glomeruli were analyzed per mouse and quantification was using imageJ.

Results: DOX-mice developed significantly increased Albumin-to-creatinine ratios starting at 2 weeks compared to controls.



Proteinuria persisted at 8 weeks of DOX-feeding. No light microscopic changes were detectable on PAS-stained sections in DOX- or control-mice in glomerular mesangial matrix expansion or intratubular protein casts upto 8-weeks of DOX feeding. Assessment of WT-1 stained nuclei/ glomeruli by immunofluorescence (IF) showed no reduction in podocyte number at 4- or 8-weeks in DOX-mice compared to controls (p=ns; n=3 each). However, by IF, significant reduction in area and intensity of glomerular synaptopodin staining was observed by 4 weeks in DOX-mice compared to controls ($p<0.01$; n=3 each at 4-wks, Fig 2). Electron microscopic studies are ongoing.

Conclusions: Our preliminary findings suggest that inducible and global knockdown of Shroom3 induces proteinuria with features of podocyte dedifferentiation without evidence of podocyte loss. Further studies are needed to elucidate the precise role of Shroom3 in proteinuria and its function in the glomerular filtration barrier.

FR-PO326

Protective Role of Cyclodextrin in Focal Segmental Glomerulosclerosis (FSGS) Alla Mitrofanova,[1,2] Patricia R. Wahl Pristau,[1] Ximena A. Morales,[1] Mayrin Correa-Medina,[1] Christopher E. Pedigo,[1] Gloria Michelle Ducasa,[1] George William Burke,[2] Sebastian Martini,[3] Matthias Kretzler,[3,4] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]Katz Family Drug Discovery Center, Nephrology & Hypertension, Univ of Miami, FL; [2]Surgery, Univ of Miami, FL; [3]Internal Medicine, Nephrology, Univ of Michigan, MI; [4]Computational Medicine & Bioinformatics, Univ of Michigan, MI.*

Background: We recently demonstrated that cholesterol accumulation contributes to podocyte injury in diabetic kidney disease (DKD), where 2-hydroxypropyl-β-cyclodextrin (CD) protects podocytes from cholesterol-dependent damage *in vitro* and *in vivo*. We hypothesize that lipid related genes are affected in glomeruli of patients with primary FSGS and treatment with CD protects podocytes in experimental FSGS.

Methods: Microarray analysis on glomerular transcripts of lipid-related genes from patients with FSGS (n=54) and from normal living donors (n=6) were obtained from patients enrolled in NEPTUNE, a longitudinal observational cohort looking at individuals with proteinuria. 5-week-old BALB/c female mice were injected with a single intravenous dose of adriamycin (ADR, 11 mg/kg) to develop FSGS-like lesions. 24-hours after ADR injection, osmotic pumps with CD in 0.9% saline solution (40 mg/kg/day) were implanted under the skin for 10 weeks. Measurements of body weight and urine collections for ACR (Albumin/creatinine ratios) were performed weekly. At time of sacrifice, serum creatinine and Blood Urea Nitrogen (BUN) were determined and kidneys collected for histological analysis.

Results: Microarray analysis of the glomerular transcripts in the NEPTUNE cohort demonstrated that cholesterol efflux related genes, such as PLIN3, S1PR2, S1PR4, S1PR1, and lipid dysmetabolism related genes, such as SCD, LDLR, ABCG1, were increased in FSGS. CD administration reduced mesangial expansion as well as ACR and BUN observed at 10 weeks in the ADR+CD group compared to the ADR group ($p<0.05$). No changes in body weight were found.

Conclusions: We concluded that glomerular lipids are altered in FSGS and that 2-hydroxypropyl-β-cyclodextrin protected podocytes in an experimental model of FSGS. Our data suggest that CD could be used as a safe and effective drug therapy in FSGS patients.

FR-PO327

Podocyte-Derived CXCL12 Has a Dual Role in Glomerular Injury and Regeneration Simone Romoli, Santhosh Kumar Vr, Shrikant R. Mulay, Hans J. Anders. *Nephrologisches Zentrum, Klinikum der Univ Muenchen, Munich, Bavaria, Germany.*

Background: Stromal-derived factor (SDF)-1/CXCL12 is a homeostatic chemokine facilitating homing and activation of stem cells. Podocytes constitutively produce CXCL12, hence, we speculated on a role of CXCL12 in glomerular regeneration upon injury.

Methods: Glomerular injury was induced by a single *i.v.* injection of 13mg/kg adriamycin (ADR) in male Balb/c mice, which received either the CXCL12 inhibitor NOX-A12 or the inactive control s.c. at 13.4mg/kg thrice a week. Human renal progenitor cell properties (RPC) were used for *in-vitro* studies.

Results: ADR-induced proteinuria peaked at day 7 (injury phase), which subsequently declined without returning back to baseline and being associated within FSGS lesions after 14 days (repair phase). CXCL12 blockade aggravated ADR-induced A/C and podocyte loss at day 7, which implies an autocrine role of CXCL12 for podocyte survival. In contrast, CXCL12 blockade reduced A/C levels and the glomerular sclerosis scores as well as increased podocyte numbers at 14 days indicating a beneficial effect of CXCL12 blockade during the repair phase. The pro-survival effect of CXCL12 on podocytes was further confirmed in a model of diphtheria toxin-induced podocyte depletion using CXCL12 blockade. To investigate the dual effect of CXCL12, we focused on the Notch signaling pathway. ADR injection reduced renal Notch expression, which was reversed following CXCL12 blockade. *In-vitro* studies with RPC revealed that CXCL12 suppressed RPC proliferation, which was reversed with CXCL12inhibitor. Similar results were obtained when RPC were exposed to supernatants from necrotic podocytes. CXCL12 blockade also increased the capacity of RPC to differentiate into podocytes.

Conclusions: Podocyte-derived CXCL12 has a dual role in glomerular injury. CXCL12 protects podocytes during the injury phase in an autocrine manner by suppressing Notch signaling, which otherwise triggers mitotic catastrophe and podocte loss. Podocyte-derived CXCL12 assures Notch-mediated quiescence of RPC. Our data also demonstrate that therapeutic CXCL12 inhibition in glomerular injury can improve long term outcomes possibly by enforcing the intrinsic regenerative capacity of RPC.

FR-PO328

Shank2 Modulates Glutamatergic Signaling in Podocytes Evgenia Dobrinskikh,[1] Linda Lewis,[1] R. Brian Doctor,[2] Judith Blaine.[1] *[1]Medicine, Univ of Colorado, Aurora, CO; [2]Biology, Univ of Mississippi, Oxford, MS.*

Background: Shank2 is a large scaffolding protein that is a master regulator of glutamate receptors at the neuronal postsynaptic density. Knockout (KO) of Shank2 in mice leads to autistic behaviours and abnormal glutamatergic signaling in neurons. Podocytes have also been shown to express functional N-methyl D aspartate (NMDA) and metabotropic glutamate receptor 1 (mGluR1) receptors which are both members of the glutamate receptor family.

Results: We have found that podocytes express Shank2 *in vivo* and *in vitro*. Since Shank2 plays an important role in regulating glutamate receptor function, we examined the effect of Shank2 knockout on NMDA and mGluR1 expression and function in podocytes. Shank2 KO resulted in decreased expression of NMDA and mGluR1 receptors in glomeruli. We isolated podocytes from wild type and Shank2 knockout mice and created conditionally immortalized podocyte lines. Conditionally immortalized Shank2 KO podocytes also demonstrated decreased expression and altered localization of glutamate receptors. In neurons, activation of glutamate receptors modulates intracellular calcium levels by allowing calcium influx into the cell (NMDA receptors) or release of calcium from intracellular stores (mGluR1). Using Fluo-4, a cell permeant calcium sensing dye, we examined intracellular calcium levels in wild type and Shank2 KO podocytes. At baseline, Shank2 knockout podocytes had significantly fewer calcium spikes than wild type podocytes. Treatment with NMDA and glutamate increased the number of calcium spikes in both wild type and Shank2 KO podocytes but the number of spikes in the KO podocytes was significantly reduced compared to wild type. Podocytes have been shown to communicate with each other via calcium waves. To examine podocyte to podocyte communication after injury, we "burned" a podocyte using high intensity laser power and then examined calcium wave propagation from the site of injury. After burning, wild type podocytes exhibited calcium waves emanating from the injured podocyte whereas no waves were seen in the knockouts.

Conclusions: Taken together these data indicate that Shank2 regulates glutamate receptor function in podocytes.

FR-PO329

Podocytes Transcytose Albumin and IgG Using the Neonatal Fc Receptor (FcRn) In Vitro and In Vivo Evgenia Dobrinskikh,[1] Linda Lewis,[1] Jeffrey B. Kopp,[2] Judith Blaine.[1] *[1]Medicine, Univ of Colorado, Denver, CO; [2]Kidney Disease Section, NIDDK, NIH, Bethesda, MD.*

Background: Proteinuria is strongly associated with kidney disease progression. Podocytes are key constituents of the glomerular filtration barrier (GFB), which determines the selectivity of protein filtration. By even the most conservative estimates between 2 and 9 g of serum proteins a day normally pass through the GFB. The molecular mechanisms whereby podocytes handle albumin and IgG remain to be fully determined.

Results: We have found that transcytosis is the major pathway whereby cultured podocytes handle albumin and IgG. In other epithelial cell types, the neonatal Fc receptor (FcRn) is required to transcytose endocytosed albumin and IgG, thereby salvaging these proteins from degradative pathways. To examine the role of FcRn in albumin and IgG transcytosis in podocytes, we knocked down FcRn in cultured podocytes using lentiviral shRNA. FcRn knockdown (KD) resulted in a 71±3% decrease in FcRn expression compared to control. In an in vitro transcytosis assay, FcRn KD increased intracellular accumulation and decreased appearance of albumin and IgG in the supernatant, suggesting impaired transcytosis, but the differences were not statistically significant, possibly due to residual FcRn. We therefore isolated podocytes from wild type (WT) and FcRn knockout (KO) mice and created conditionally immortalized WT and KO podocyte lines. Knockout of FcRn resulted in significantly increased intracellular accumulation, assessed by immunostaining and Western blot (densitometric analysis of intracellular protein 1 hr after loading showed 0.37 ± 0.1 (WT) vs 0.97 ± 0.2 (KO), $p<0.05$ for albumin and 0.52 ± 0.04 (WT) versus 1.03 ± 0.19 (KO), $p<0.05$ for IgG), and decreased appearance of supernatant albumin or IgG, indicating defective transcytosis. We extended our studies to an in vivo model by creating a podocyte-specific FcRn KO mouse. Podocyte-specific FcRn KO mice demonstrated intraglomerular accumulation of IgG by 8 weeks of age, assessed by immunostaining. Studies of albuminuria are in progress.

Conclusions: Taken together, these studies indicate that podocytes in vitro and in vivo transcytose albumin and IgG using FcRn.

Transcriptional Reprogramming by Wilms' Tumor 1 and FoxC2 in Glomerular Disease Sandrine S. Ettou,[1] Lucy Jung,[3] Martin Kann,[1,2] Mary E. Taglienti,[1] Peter Park,[3] Jordan A. Kreidberg.[1] *[1]Nephrology, Boston Children's Hospital, Boston, MA; [2]Internal Medicine and Center for Molecular Medicine, Univ of Cologne, Cologne, Germany; [3]Center for Biomedical Informatics, Harvard Medical School, Boston, MA.*

Background: Foot process effacement and proteinuria, representing a breakdown of the glomerular filtration barrier (GFB) are typically accompanied by decreased expression of key podocyte proteins. We sought to determine whether decreased expression of key podocyte proteins was caused by transcriptional reprogramming in the injured podocyte. We reported a Wilms' tumor-1 (WT1) ChIP-Seq study that identified components of the GFB and many other important podocyte genes as WT1 bound genes. Many WT1 target genes in podocytes also appear to be bound by FoxC2, including Podocin (*Nphs2*), Sulfatase 1 (*Sulf1*) and Synaptopodin (*Synpo*).

Methods: We now use ChIP-Seq to study the DNA binding of WT1 to target genes in the context of Adriamycin-induced podocyte injury that is considered a model for human FSGS. WT1 ChIP-Seq was performed using isolated glomeruli from 6 days post-injection or control Balb/C mice. FoxC2 binding was determined by direct ChIP-qPCR.

Results: Following injury, expression of WT1 and FoxC2 decreased in podocytes, as did binding of WT1 and FoxC2 to their common targets. WT1/FoxC2 target gene expression was also reduced. In contrast to these WT1/FoxC2 target genes that represent a set of genes required for normal podocyte function, we identified a second set of WT1-bound genes, not bound by FoxC2, including *Hdac5* and *7,* whose expression increased after podocyte injury and for which WT1 binding decreased, suggesting that WT1 acts as a repressor for a distinct set of target genes.

WT1 binding at known target genes showed both decreased and increased peak intensity after treatment suggesting that WT1 regulation of gene expression is complex and may involve activating and repressive functions.

Conclusions: These results suggest a model whereby WT1 and FoxC2 activate gene expression in normal podocytes, WT1 represses other genes in normal podocytes independently of FoxC2.

A Basophilic Kinase Site at the N-Terminus of TRPC6 Controls Channel Activity Henning Hagmann,[1] Markus M. Rinschen,[1] Alexander Kuczkowski,[1] Stuart E. Dryer,[2] Bernhard Schermer,[1] Thomas Benzing,[1] Paul T. Brinkkoetter.[1] *[1]Nephrology, Univ Hospital Cologne, Cologne, Germany; [2]Bichemistry, Univ of Houston, Houston, TX.*

Background: The non-selective cation channel TRPC6 plays a pivotal role in the development of proteinuric kidney disease. Hyperactivity of TRPC6 either through gain of function mutations, increased total protein levels or membrane abundance of the channel protein has been associated with glomerular disease.

Results: To investigate regulation of the TRPC6 channel activity we conducted mass spectrometry experiments to screen for phosphorylation sites in the TRPC6 protein. We identified several new as well as previously known phospho-peptides. The serine residues in position 13 and 14 of the human TRPC6 protein are phosphorylated and embedded in a basophilic kinase motif. Substitution of the serine residue in position 14 with alanine (S14A) leads to reduced TRPC6 conductance in voltage clamp experiments in Xenopus oocytes. The atypical cyclin-dependent kinase (Cdk5), a serine- threonine-kinase expressed in the podocyte, is directed to basophilic motives. In the podocyte, Cdk5 is activated by the specific activators p35, p25, and Cyclin I. In cell culture experiments a direct phosphorylation of TRPC6 by Cdk5/p35 at position S14 could be confirmed with mass spectrometry and radioactive in-vitro kinase assays. Co-expression of Cdk5/p35 and TRPC6 enhanced channel conductivity of TRPC6 in voltage clamp experiments. This effect was abrogated by the amino acid substitution S14A.

Conclusions: A basophilic kinase site at the N-terminus of TRPC6 was identified which controls channel activity. As exemplarily shown for Cdk5/p35, basophilic kinases phosphorylate TRPC6 at serine 14 and affect channel function. This site may serve as a molecular switch for TRPC6 activity and as a potential future drug target.

Hantaviruses Associate with Actin Fibers and Cause Podocyte Damage Stefan Hägele,[1] Alexandra Kowalski,[1] Jochen Reiser,[2] Martin G. Zeier,[1] Ellen Krautkrämer.[1] *[1]Nephrology, Univ Hospital Heidelberg, Heidelberg, Germany; [2]Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: Characteristic for the clinical picture of Old World hantaviruses is an acute renal failure with often massive non-selective proteinuria. Previously, we showed that cell-to-cell contact proteins were disrupted and levels were decreased in infected human renal cells, correlating with the clinical picture. However, the exact mechanisms driving hantaviral pathogenesis are not well characterized.

Methods: Renal biopsies of patients with acute hantavirus infection were analyzed by electron microscopy. A human podocyte cell line was used for infection with Hantaan virus (HTNV). Cell-to-cell contact proteins were analyzed by immunoblotting, qRT-PCR and immunofluorescence. The cytoskeleton was examined by confocal microscopy and by depolymerising drugs. Cell motility was measured by migration assays.

Results: Analysis of renal biopsies revealed podocyte foot process effacement with loss of cell-to-cell contacts. To examine the underlying mechanism of hantavirus-induced alterations, we performed in vitro infection studies. We showed that HTNV had no influence on transcription levels of cell-to-cell contact proteins, indicating another mechanism of cell-to-cell contact disruption. Next, we focused on an impact on the cytoskeleton which is important for barrier function. We detected a filamentous pattern of the hantaviral nucleocapsid (N) protein which was associated with actin fibers. This N protein localization depends on the integrity of the actin cytoskeleton, because the filamentous pattern disappeared after actin depolymerization. Correspondingly, we measured decreased viral release levels after loss of N protein filaments. During infection, we revealed impaired podocyte motility as a functional consequence due to hantavirus-induced effects on actin dynamics.

Conclusions: These results demonstrate that hantavirus infection leads to podocyte injury by morphological changes. Disruption of cell-to-cell contacts may be caused by the association of N protein and actin leading to changes in podocyte motility. These findings provide useful insights into the mechanism inducing renal failure.

ARF6: A New Player in Injury-Induced Podocyte Effacement Jamie Lin,[1] Jin Seok Jeon,[2] Qingfeng Fan,[1] Lawrence B. Holzman.[1] *[1]Renal-Electrolyte and Hypertension Div, Univ of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Dept of Nephrology, Soon Chun Hyang Univ Hospital, Seoul, Korea.*

Background: The transmembrane slit-diaphragm protein nephrin is tyrosine-phosphorylated and endocytosed during acute podocyte injury, resulting in cell spreading and effacement *in vivo*. We hypothesize that these events are facilitated by ARF6, a small GTPase that regulates endocytosis, endosomal trafficking, and actin dynamics possibly through regulation of Rac1, a Rho GTPase.

Methods: Using human podocyte cultures transfected with chimeric nephrin intracellular domain, we investigated the molecular mechanisms underlying its role in nephrin signaling. Using wild-type, constitutively-active, dominant-negative, and siRNA-knock-down of ARF6, we assessed lamellipodia activity (a marker of cell spreading) and podocyte motility.

Results: Results of co-immunopreciptation suggested that activated nephrin formed a signaling complex with ARF6. Furthermore, nephrin tyrosine phosphorylation increased ARF6 activity in cultured podocytes. A constitutively active ARF6 mutant resulted in increased lamellipodia formation compared to wild-type ARF6, while dominant-negative ARF6 mutant resulted in decreased lamellipodia formation. A scratch assay of ARF6 knock-down cultured podocytes revealed slowed cell migration.

Conclusions: Together, our results suggest that ARF6 is an important protein involved in the regulation of injury-induced podocyte cytoskeletal rearrangement. Inhibition of ARF6 might prevent podocyte effacement and confer a protective phenotype *in vivo*, making it an attractive target for the amelioration of glomerular disease.

Albumin Sieving Coefficient in Isolated Perfused Kidney: Effects of EDTA Turgay Saritas, Ralf Hausmann, Thiago Strieder, Jürgen Floege, Marcus J. Moeller. *Nephrology and Immunology, Univ Hospital RWH Aachen, Aachen, NRW, Germany.*

Background: It is still controversial how the glomerular filter works. The widely accepted pore model is limited by multiple unresolved and incomplete issues. Previously, we have proposed that an electrical field is generated across the glomerular filter by forced filtration of the small solutes in plasma (i.e. water, Na^+, K^+, Cl^-, HCO_3^-, and divalent ions). The electrophoretic force of this electrical field retains plasma proteins within the circulation. If validated, this novel 'electro-kinetic model' could explain most of the remaining issues about the glomerular filter. The model predicts a crucial role of the divalent cations in the perfusate ($Ca2^+$and Mg^{2+}) for the generation of the electrical field ('streaming potential'). The aim of the present study was to test this.

Methods: According to the current physical model for the generation of streaming potentials with a reversed polarity, a physical phenomenon termed 'over-charging' is predicted to occur which requires the presence of divalent cations. Thus, to verify the 'electrokinetic model', divalent cations are predicted to be required for generation of the electrical field and a physiological low albumin sieving coefficient. Isolated perfused rat kidneys (IPK) were perfused-fixed with glutaraldehyde to exclude any cellular effects. Subsequently, the absolute concentrations of the major divalent cations (Ca^{2+}, Mg^{2+}) were manipulated in our IPK model. Albumin solutions containing 0.9 mM Ca^{2+} and 0.5 mM Mg^{2+}or 0.52 mM ethylenediaminetetraacetic acid (EDTA) were used to perfuse the IPK to achieve normal or very low Ca^{2+} and Mg^{2+} concentrations within the perfusate.

Results: Decreased polycation concentrations resulted in a significant increase of the albumin-sieving coefficient from a baseline value of 0.0031±0.00024 to 0.0068±0.0014 (+120%, n=5, p< 0.05). Changes in albumin sieving coefficient were partially reversible. The glomerular filtration rate was stable.

Conclusions: The results indicate that Ca^{2+} and Mg^{2+} are required for the integrity of the glomerular filter. Cellular artifacts or active transport processes were excluded by fixation. The results support the electrokinetic model of glomerular filtration.

γ Isoform of Phosphoinositide 3 Kinase Plays a Role for Podocyte Damage and Is a Potential Marker for Glomerular Sclerosis Tomoko Hayashida, Xiaoyan Liang, H. William Schnaper. *Pediatrics, Northwestern Univ, Chicago, IL.*

Background: We recently reported that, in the Adriamycin (ADR)-induced mouse glomerular sclerosis (GS) model, the γ isoform of the p110 catalytic subunit (p110γ) of phosphoinositide 3 kinase is selectively upregulated in podocytes of the sclerosing glomeruli, and that a specific inhibitor to p110γ (AS605240) prevented proteinuria and GS. Here, we evaluated the molecular mechanisms by which p110γ mediates podocyte damage *in vitro* and a possible role for p110γ in a mouse genetic model of GS *in vivo.*

Methods: $CD2AP^{+/-}$, $synaptopodin^{+/-}$ mice develop FSGS-like lesion to a variable degree at age 8-9 months. Mice were sacrificed at 8 months old and glomerular COL1A2 mRNA content was evaluated by qPCR of laser-captured glomeruli. Fixed kidney sections were stained for p110γ, and positive staining was counted in manually identified glomeruli (~100 gloms per section) using the TissueGnostics system. *In vitro*, podocytes were isolated from wild type (WT) or p110γ kinase-dead knock-in (KD) mouse mated with the Immortomouse, and cellular signaling was evaluated in cells overexpressing GFP-actin with or without ADR treatment by live-cell imaging with an Andor spinning confocal microscope.

Results: The mice showed variable levels of proteinuria and GS. p110γ-positive cells per total nuclei in glomeruli correlated significantly with glomerular COL1A2 mRNA content. In culture, p110γ KD podocytes, but not WT cells, demonstrated increased membrane ruffling along with distinct Rac1 staining at the membrane, and KD podocytes were resistant to *in vitro* ADR treatment. WT cells expressing constitutively active p110γ showed decreased cytoskeletal assembly and cytoDEATH early apoptosis marker staining was detected, suggesting that p110γ activity directly mediates podocyte dysfunction.

Conclusions: p110γ expression in podocyte correlates with degree of GS, and therefore, a potential maker for GS. p110γ activity mediates podocyte damage by affecting signals that is critical for cytoskeletal structure.

Effects of FSGS-Associated Mutations on the Stability and Function of Myosin-1 Mira Krendel, Jing Bi, Robert T. Carroll, Michael L. James, Jessica L. Ouderkirk, Vladimir Sirotkin. *Cell and Developmental Biology, SUNY Upstate Medical Univ, Syracuse, NY.*

Background: Myo1e is expressed in podocytes and plays a key role in regulating the integrity of their cell-cell junctions, however, the effects of FSGS mutations on Myo1e motor activity and stability have not been directly tested. In this study, we used a simple model organism, fission yeast Schizosaccharomyces pombe, to test the effects of FSGS-associated mutations on myosin activity. Fission yeast has only one class I myosin, Myo1, which is involved in actin patch assembly at the sites of endocytosis.

Methods: The amino acid residues mutated in the FSGS patients are conserved between human Myo1e and yeast Myo1, which allowed us to introduce equivalent mutations into yeast myosin and use the resulting mutant strains for functional analysis. Myo1-mGFP localization and stability was analyzed using fluorescence imaging and Western blotting, while Myo1 functional activity was tested using growth and endocytosis assays.

Results: Yeast strains expressing mutant Myo1 exhibited defects in growth and endocytosis similar to those observed in the myo1 deletion strain. These mutations also disrupted Myo1 localization to endocytic actin patches and resulted in mis-localization of Myo1 to eisosomes, linear membrane microdomains found in yeast cells. While both mutants examined in this study exhibited loss of function, one of these mutants was also characterized by the decreased protein stability.

Conclusions: Using the yeast model system we were able to determine that the kidney disease-associated mutations impair myosin functional activity and have differential effects on protein stability. This study provides the first example of using fission yeast as a model system to test the effects of FSGS mutations on Myo1e function. This novel system allowed us to definitively establish for the first time the connection between the myosin motor activity and its ability to support normal glomerular filtration.

FR-PO337

Vinculin Binds Zonula Occludens-1 (ZO-1) and Is Required for Podocyte Stabilization of the Slit Diaphragm following Injury Xuefei Tian, Kazunori Inoue, Shuta Ishibe. *Dept of Internal Medicine, Yale Univ School of Medicine, New Haven, CT.*

Background: Cell-matrix interactions and intercellular junctions in podocytes are important factors to prevent protein leakage through the glomerular filtration barrier. Vinculin, a cytoplasmic protein, links the actin filaments to integrin-based cell-matrix proteins and cadherin-based intercellular junctions. We have observed that vinculin is highly expressed in podocytes, and appears to be critical in maintaining slit diaphragm integrity following injury through its interaction with ZO-1.

Methods: Wild type and Vinculin (*Vcl*) podocyte knock out (KO) mice were analyzed to determine the role of vinculin *in vivo*, and primary podocytes were isolated for *in vitro* studies.

Results: Podocyte specific ablation of *Vcl* resulted in no significant difference in body weight, albuminuria, and kidney histology up to 18 months when compared to littermate controls. However, Pod-*Vcl* KO mice had significantly increased albumin/creatinine ratios following lipopolysaccharide (LPS) or rabbit anti-mouse glomerular basal membrane (NTS) induced podocyte damage respectively (284±40 vs 411±31 μg/mg, and 205±28 vs 314±38 μg/mg, P<0.05). In addition, loss of *Vcl* in podocytes resulted in worsened foot process effacement. Co-immunoprecipitation assays demonstrated that vinculin associates with ZO-1 in the primary podocytes and isolated glomeruli respectively. Cell fractionation of control and Pod-*Vcl* KO podocytes treated with either LPS or protamine sulfate (PS) revealed a mislocalization of ZO-1 and nephrin to the cytoplasm in the mutant podocytes when compared to the control. These findings were further validated by immunofluorescence imaging of the primary podocytes following LPS or PS stimulation and from isolated glomeruli following LPS or NTS stimulation. No changes in cell adhesion or focal adhesion number were observed between the control and Pod-*Vcl* KO podocytes following LPS or PS stimulation on various substrates.

Conclusions: Our results reveal an association between vinculin and ZO-1 in podocytes. Loss of *Vcl* in podocytes results in the mislocalization of slit diaphram proteins ZO-1 and nephrin following injury, thus exacerbating proteinuria.

AT_1 Receptors in Podocytes Control GFR and Susceptibility to Kidney Injury Stacy Alana Johnson,[1] Tiffani N. White,[1] Susan B. Gurley,[1,2] Thomas M. Coffman.[1,2,3] *[1]Duke Univ; [2]Durham VA; [3]Duke-NUS.*

Background: Angiotensin II, acting via AT_1 receptors, plays a critical role in CKD progression. Pharmacologic blockade of AT_1 receptors reduces albuminuria and this is linked to its efficacy in CKD. Within the kidney, the density of AT_1 receptor expression is highest in the glomerulus, where AT_1 receptors are expressed in multiple cell lineages and are involved in regulating glomerular pressures and GFR. However, the key cellular sites of action in the glomerulus involved in physiological regulation and in promoting proteinuria have not been directly defined. Since podocyte dysfunction and injury have been implicated in the pathogenesis of many glomerulopathies, we investigated the role of AT_1 receptors in podocytes using cell-specific gene targeting.

Methods: Because the minor AT_1 receptor isoform (AT_{1B}) is expressed at significant levels in podocytes, we generated mice lacking all AT_1 receptors in the podocyte (PodKOs) by carrying out podocyte-specific, Cre-mediated excision of a conditional allele of the major AT_1 receptor isoform (AT_{1A}) on an AT_{1B}-null background.

Results: PodKO mice develop normally with kidney weights similar to controls (6.9±0.5 vs 7.0 ± 0.3 mg/g BW) and their glomerular morphology appears normal. GFR was significantly reduced in 24-week old PodKOs (8.9±3.5 µl $min^{-1}g^{-1}$) compared to controls (29.5±4.5 µl $min^{-1}g^{-1}$; p=0.04), but there was no significant difference in the low levels of albumin excretion between the groups. To determine whether the elimination of AT_1 receptors from podocytes impacts albuminuria and kidney injury in a model with high levels of Ang II, a transgene (*RenTg*) driving constitutive expression of renin was crossed onto the PodKO background. At 24 weeks of age, levels of albuminuria were increased in RenTg mice (210±71 µg/24 hr) compared to controls (29±9 µg/24 hr; p=0.02), but this increase in albuminuria was unaffected in RenTg-PodKOs (229±38 µg/24hr). Despite similar levels of albumin excretion, kidneys from RenTg-PodKO mice had exaggerated kidney injury with more glomerulosclerosis, mesangial expansion and tubular casts.

Conclusions: Our results suggest that AT_1 receptors in podocytes do not promote albuminuria and may protect against glomerular injury.

H_2O_2 Production by Nox4 Drives Ang II – Dependent Calcium Influx Through TRPC6 Channels in the Podocytes Daria Ilatovskaya, Oleg Palygin, Leonid S. Shuyskiy, Alexander Staruschenko. *Physiology, Medical College of Wisconsin, Milwaukee, WI.*

Background: Improper Ca^{2+} handling by the podocyte can result in cell damage and loss of function. Podocyte depletion and associated glomerulosclerosis are typical for progressive chronic nephropathies, which have been associated with elevated levels of ROS, including H_2O_2. One of the key mediators of Ca^{2+} flux in the podocytes is a TRCP6 channel. The goal of this study was to provide a mechanistic insight into the Ang II-dependent regulation of TRPC6 channel.

Methods: Changes in intracellular Ca^{2+} levels were measured with live confocal microscopy in podocytes of isolated glomeruli. Patch clamp analysis was performed to assess the activity of TRPC channels in this preparation. Enzymatic biosensors technique was applied to determine H_2O_2 release in the kidney cortex and isolated glomeruli.

Results: NADPH oxidase 4 (Nox4) is one of the main renal sources of H_2O_2. Here we demonstrated substantial attenuation of Ang II-evoked H_2O_2 release in the kidney and glomeruli suspension of the $Nox4^{-/-}$ rats, generated on the Dahl salt-sensitive (SS) background. Furthermore, basal Ca^{2+} levels and Ca^{2+} influx in response to Ang II were decreased in the podocytes of $Nox4^{-/-}$ rats compared to SS rats. Basal Ca^{2+} level increase was also attenuated in $Nox4^{-/-}$ podocytes when rats were fed a high salt diet. To further test effects of H_2O_2, we employed patch clamp analysis. The data revealed an acute increase in TRPC6 channel open probability in response to H_2O_2. A dose-dependent increase in intracellular Ca^{2+} was observed when H_2O_2 was applied (2.5 µM to 300 µM; EC_{50}=56 µM). Lower concentrations of H_2O_2 caused a transient Ca^{2+} peak, whereas doses of 50 µM and higher evoked a long-term Ca^{2+} elevation attributed to apoptotic effects. Experiments with $TRPC6^{-/-}$ and TRPC5/6 double KO mice showed a diminished Ca^{2+} response to H_2O_2.

Conclusions: Our data indicate that in the podocytes Ang II stimulates generation of H_2O_2 by the Nox4, which evokes a dose-dependent Ca^{2+} influx through TRPC6 channels. This mechanism might be an important determinant of podocyte loss in kidney diseases associated with oxidative stress and elevated interstitial Ang II levels.

FR-PO340

Role of Unliganded Vitamin D Receptor (VDR) in Providing Podocyte Protection During AT1R Blockade (BLK) in Adverse Milieus Tejinder Singh,[1] Kamesh R. Ayasolla,[1] Shabirul Haque,[1] Nirupama Chandel,[1] Himanshu Vashistha,[2] Ashwani Malhotra,[1] Leonard G. Meggs,[2] Pravin C. Singhal.[1] *[1]Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Ochsner Health System, New Orleans, LA.*

Background: AT1R-BLK is used extensively to slow down the progression of kidney diseases. We hypothesized that AT1R-BLK provides podocyte protection through regulation of VDR and silencing mediator of retinoic acid and thyroid hormone receptor (SMRT) expression under adverse milieus (AMs).

Methods: Human podocytes (HPs) were treated with losartan (AT1RB) or VDR agonist (EB1089;VDA) with or without AMs (HIV/high glucose/Ang II; 48h) and evaluated for mRNA and protein expressions of Cytochrome P450 Family 24 (CYP24)A1, VDR and molecular markers of co-repressor and co-activator complexes. Protein interactions in these complexes were evaluated by immunoprecipiatation (IP) studies followed by Western blot analysis. Role of protesomal degrdation of VDR in AMs was determined.

Results: Both AT1R-BLK and VDA stimulated VDR complexes formation that differed in their composition and in their functionality. AT1R-BLK- induced VDR complexes contained unliganded VDR, SMRT, and phospho-histone deacetylase (HDAC)3, whereas, VDA-VDR complexes were constituted by liganded VDR and CBP/p300. AT1R-BLK-induced complexes attenuated podocyte acetyl- histone (Ac-H)3 levels and CYP24A1 expression, thus indicating their de-acetylasing and repressive properties. On the other hand, VD-VDR complexes not only increased podocyte Ac-H3 levels but also enhanced CYP24A1 expression, thus suggesting their acetylating and gene activation properties. AT1R-BLK- induced podocyte SMRT inhibited expression of the pro-apoptotic gene BAX through down regulation of Wip1 and phosphorylation of Chk2 in high glucose milieu. Since SMRT-depleted podocytes lacked AT1R-BLK-mediated protection against DNA damage, it appears that SMRT is necessary for DNA repairs during AT1R-BLK.

Conclusions: AT1R-BLK provides podocyte protection in AMs predominantly through SMRT expression and partly through unliganded VDR expression in 1, $25(OH)_2D$ deficient states, on the other hand, ATR1-BLK contributes to liganded VDR expression in 1, $25(OH)_2D$ sufficient states.

FR-PO341

Enhanced S-Nitrosylation and N-Glycosylation of Podocin-R138Q May Contribute to Its Defective Trafficking and Rapid Degradation Maria Carmen Serrano-Perez,[1] Fabien Nevo,[1] Christelle Arrondel,[1] Alda Tufro,[2] Corinne Antignac,[1] Geraldine Mollet.[1] *[1]Inserm U1163 - Imagine Inst - Paris Descartes Univ-Sorbonne Paris Cité, France; [2]Yale Univ School of Medicine-Dept of Pediatrics.*

Background: Missense mutations in the *NPHS2* gene, encoding podocin, are a major cause of inherited and sporadic cases of steroid-resistant nephrotic syndrome (SRNS). Among them, those encoding endoplasmic reticulum (ER)-retained mutant proteins, e.g. R138Q, correlate with the most severe cases of SRNS.

Methods: We generated two human podocyte cell lines stably expressing 2HA-$podocin^{wt}$ or 2HA-$podocin^{R138Q}$ to perform comparative studies on podocin post-translational modifications and podocin degradation.

Results: We detected increased podocin S-nitrosylation and N-glycosylation in 2HA-$podocin^{R138Q}$ vs. 2HA-$podocin^{wt}$ podocytes, which may modify podocin topology, degradation and trafficking. We also suggest that a further interaction of $podocin^{R138Q}$ with the ER-chaperone calnexin may contribute to its ER-retention. In line with the higher degradation rate of $podocin^{R138Q}$ previously found in R140Q knock-in mice, we found that non-glycosylated (ng) $podocin^{R138Q}$ has a dramatically shorter half-life than $podocin^{wt}$. Moreover, the N-glycosylated forms of $podocin^{R138Q}$ are more stable than its non-glycosylated fraction. We also show that ng-$podocin^{R138Q}$ is mainly degraded by the proteasome, whereas ng-$podocin^{wt}$ can be degraded by both the proteasomal and the lysosomal proteolytic machineries. Furthermore, preventing ng-$podocin^{R138Q}$ degradation allows its partial localization to the podocyte filopodia, improves the ratio between its non-glycosylated and glycosylated forms and reduces its interaction with calnexin.

Conclusions: These findings show podocin S-nitrosylation for the first time and suggest that increased S-nitrosylation and N-glycosylation may contribute to the defective trafficking and degradation of $podocin^{R138Q}$, the product of the most frequent human podocin missense mutation, and possibly of other ER-retained podocin missense mutants.

RAS Inhibition Enhances Proliferation and Migration of Cells of Renin Lineage (CoRL) as Progenitors in Experimental FSGS Julia Lichtnekert,[1] Diana G. Eng,[1] Jeffrey W. Pippin,[1] Kenneth W. Gross,[2] Stuart J. Shankland.[1] *[1]Div of Nephrology, Univ of Washington, Seattle, WA; [2]Dept of Molecular and Cellular Biology, Roswell Park Cancer Inst, Buffalo, NY.*

Background: RAS inhibitors are used therapeutically in proteinuric glomerular diseases. In focal segmental glomerulosclerosis (FSGS) where podocyte number is depleted, recent data showed that ACE-Inhibitors could improve podocyte number. Because adult podocytes cannot proliferate, their replacement by renal progenitors is critical for their regeneration in disease. The impact of RAS blockade on adult podocyte progenitors is not well understood.

Methods: Experimental FSGS characterized by podocyte depletion was induced by an anti-podocyte antibody in two strains of Cells of Renin Lineage (CoRL) reporter mice (RenCre and RenCreER) where CoRL are fate mapped. Diseased mice were randomized at day 3, when podocyte number was depleted by 40%, to receive Enalapril or Losartan, or the controls Hydralazine or water. BrdU was injected to monitor proliferation.

Results: Following initial podocyte depletion in all groups, podocyte number (measured by p57 staining) was higher in both Enalapril and Losartan groups on d14 and d28. This was accompanied by significantly lower proteinuria and glomerulosclerosis. The number of CoRL increased in the intra-glomerular compartment in FSGS mice given water or hydralazine. However, the number of labeled CoRL further increased significantly in FSGS mice given Enalapril or Losartan. A subset of CoRL detected in the glomerular compartment co-expressed several markers for podocytes and PEC's. RAS inhibition increased BrdU staining in CoRL in the juxta- and intraglomerular compartments, but was not seen in podocytes.

Conclusions: Following the abrupt depletion of adult podocytes in experimental FSGS, RAS blockade significantly increased their number despite the absence of their proliferation. This regeneration of adult podocytes is likely in part due to proliferation and migration of CoRL progenitor cells into the glomerular compartment. We show the first time that RAS inhibition has the potential to stimulate progenitor cells necessary for kidney repair and regeneration following podocyte depletion.

FR-PO343

ShcA Influences Nephrin Endocytosis and Protects from Glomerular Injury Claire E. Martin,[1] Kelly A. Petersen,[1] Lamine Aoudjit,[2] Tomoko Takano,[2] Nina Jones.[1] *[1]Molecular and Cellular Biology, Univ of Guelph, Guelph, ON, Canada; [2]Dept of Medicine, McGill Univ, Montreal, QC, Canada.*

Background: The transmembrane protein nephrin is a key component of the slit diaphragm (SD). It has recently been postulated that nephrin turnover plays a key role in maintaining a healthy SD, and multiple theories regarding the role of nephrin phosphorylation in endocytosis are emerging. Tyrosine phosphorylation of the cytoplasmic tail of nephrin facilitates recruitment of several signaling proteins that regulate podocyte shape and thereby permselectivity of the SD. Previous work from our lab has identified and mapped the interaction between nephrin and the ShcA adaptor protein and demonstrated an early requirement for ShcA in maintenance of the filtration barrier in mice. Given ShcA's established role in endocytosis, we now hypothesize that ShcA may regulate nephrin endocytosis to ultimately maintain filtration barrier integrity.

Methods: Multiple approaches were used to measure the influence of ShcA and ShcA domain mutants on the levels of surface nephrin and signaling downstream of nephrin. Puromycin aminonucleoside (PAN) nephrosis was induced in Sprague-Dawley rats for 0, 4, 7, or 14 days and nephrin endocytosis was monitored via biotinylation and immunofluorescence experiments.

Results: We demonstrate that ShcA expression is increased in podocytes in response to PAN injury, which is accompanied by activation of the stress-activated p38 and JNK MAP kinases. Interestingly, we found that transactivation of AP-1, which occurs downstream of nephrin as well as p38 and JNK, is attenuated by ShcA, and this effect is reversed by mutation of the ShcA SH2 domain, which mediates nephrin binding. Further investigation revealed that ShcA promotes nephrin endocytosis in a phospho-dependent manner by enhancing Src-mediated nephrin phosphorylation, its own binding to nephrin and endocytosis into EEA1-positive endosomes both *in vitro* and in PAN-treated rats.

Conclusions: Together these findings suggest a protective effect of ShcA in podocytes by influencing phospho-dependent nephrin endocytosis and possibly attenuating nephrin-mediated p38/JNK signaling in response to injury.

FR-PO344

Podocyte Specific Response to Complement Challenge Anne Katrin Dettmar,[1,2] Magdalena Riedl,[2] Fred G. Pluthero,[2] Moin Saleem,[3] Jun Oh,[1] Christoph Licht.[2] *[1]Dept of Pediatrics, Univ Medical Center Hamburg-Eppendorf; [2]Dept of Pediatric Nephrology, Hospital for Sick Children; [3]Academic Renal Unit, Univ of Bristol.*

Background: There is a multilayered system of fluid phase and surface bound complement regulatory proteins, which ensure that complement activation occurs only site specific and spares the body's own cells. Unrestricted complement activation is a main cause for damage in complement-mediated glomerulopathies such as C3G or membranous nephropathy (MN). In MN, podocytes, key components of the glomerular filtration barrier, are target of overshooting complement activation.The aim of this study was to characterize the complement defense mechanisms in podocytes and their response to complement challenge (CC).

Methods: We analyzed complement regulators by immunofluorescence, flow cytometry and qRT-PCR in immortalized human podocytes and compared them to blood grown endothelial cells (BOECs). Functionality of secreted complement factor H (CFH) was tested via a cofactor assay. In a model for CC (sensitization with antibodies against membrane-anchored complement regulators CD46, CD55 and CD59 and normal human serum (NHS)) we analyzed C3c deposition, LDH-release, and cell morphology.

Results: Podocytes showed similar levels of CD46, CD55 and CD59 as BOECs. Expression of CFH-mRNA was higher in podocytes (1.03 +/-0.27 vs. 0.25 +/-0.09 fold change, p=0.03). Podocyte secreted CFH served as active cofactor to CFI in splitting C3b. CC led to increased C3c deposition (NHS vs CC: 660+/-189 vs 5290+/-2231 MFI, p=0.05), which was complement dependent (heat inactivated serum: 211+/-25, p=0.04) . There was a significant increase in LDH release (NHS vs. complement 1.92 +/-0.98 vs. 2.30 +/-0.86 fold increase, p=0.02), and podocytes showed a reduction of stress fibres and cell size after CC.

Conclusions: In summary, podocytes expressed complement regulators in response to complement activation similar to the response found in BOECs. CFH, less abundant in BOECs, may play an important role in a complement specific stress response of podocytes. These findings might help to understand the role of podocytes in local complement activation and will help to identify new therapeutic strategies in future.

Ephrin-B1 Is Essential for the Formation and the Maintenance of the Integrity of the Slit Diaphragm Component: Inducible Podocyte-Specific Ephrin-B1 Deletion Causes Irregular Localization of Nephrin, NEPH1, CD2AP and ZO-1 Yoshiyasu Fukusumi, Hiroshi Kawachi. *Dept of Cell Biology, Inst of Nephrology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Ephrin and eph function as receptor-ligand pairs, and are reported to play multiple functions in several tissues. We have reported ephrin-B1 was expressed at the podocyte slit diaphragm (SD) and had an interaction with nephrin, a critical component of the SD (Kidney Int 72: 954, 2007). However, the function of ephrin-B at the SD is remained uncertain. In this study, the role of ephrin-B at the SD and the functional association of epnrin-B and nephrin were elucidated.

Methods: (i)The expressions of the SD components (nephrin, NEPH1, podocin, CD2AP and ZO-1) were analyzed in tamoxifen-inducible podocyte-specific Ephrin-B1 knockout (KO) mice (Podocin-CreERT2; Ephrin-B1 flox/flox). (ii)The effect of the nephrin stimulation on the molecular conformation of ephrin-B were analyzed.

Results: (i)Tamoxifen-induced inactivation of the ephrin-B1 gene at E18.5 resulted in the dislocalization of nephrin, NEPH1, CD2AP and ZO-1, although podocin dislocalization was not detected. These alterations of the molecular arrangement of the SD components were also detected in the mice of which ephrin-B1was deleted at 3 month-old with tamoxifen (KO vs. cont, n=5: nephrin, score 3.11 vs 3.40, $p<0.01$; NEPH1: 2.97 vs 3.36, $p<0.05$; CD2AP, 3.01 vs 3.24, $p<0.05$; ZO-1: 3.28 vs 3.66, $p<0.05$). (ii) Not only nephrin but also ephrin-B was phosphorylated in the rat nephrotic model caused by the injection with the antibody against nephrin, although phosphrylation of these molecules was not detected in normal rats. The phosphrylation of these molecules were detected already at 1 h after the antibody injection. The ephrin-B phosphorylation was also induced by the treatment with the anti-nephrin antibody in HEK293 cells co-transfected with ephrin-B and nephrin.

Conclusions: Ephrin-B1 is essential for the formation and the maintenance of the proper arrangement of the SD molecules. The stimulation to nephrin with the antibody phosphorylated not only nephrin but also ephrin-B, indicating ephrin-B is functionally associated with nephrin.

Ubiquitin C-Terminal Hydrolase-L1 Deficiency in Podocytes Protects from Immune Complex Nephritis in Mice Julia M. Fehlert,[1] Marlies Sachs,[1] Thorsten Wiech,[2] Rolf A. Stahl,[1] Catherine Meyer-Schwesinger.[1] *[1]Nephrology, III. Medical Clinic, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Ubiquitin C-terminal Hydrolase-L1 (UCH-L1) is a central deubiquitinating enzyme of the neuronal ubiquitin proteasomal system. UCH-L1 is thought to regulate the intracellular pool of monoubiquitin in neurons. Recently we identified a *de novo* expression of UCH-L1 in podocytes of patients with membranous nephropathy. Upregulation of UCH-L1 correlated with disease progression, accumulation of ubiquitinated proteins and altered expression of podocyte-specific proteins in human and rodent podocytes. Inhibition of UCH-L1 enzymatic function in a rat model of membranous nephropathy decreased the abnormal protein accumulation and ameliorated the clinical course of disease. We generated mice with podocyte-specific UCH-L1-deficiency to investigate the role of UCH-L1 *de novo* expression in injured podocytes.

Methods: Mice with podocyte-specific UCH-L1-deficiency were generated by Cre-Lox technology and back-crossed into the C57/BL6 background. Podocyte phenotype was evaluated by morphological (immunohistochemistry, electron microscopy) and biochemical techniques (Western blotting, proteasomal activity assays, real-time PCR) in unchallenged and anti-podocyte antibody challenged wildtype and knock-out mice.

Results: Unchallenged podocyte-specific UCH-L1-deficient mice exhibited normal podocyte morphology throughout life and delayed age-related proteinuria accompanied by a decreased accumulation of poly-ubiquitinated proteins. Following induction of anti-podocyte nephritis, podocyte-specific UCH-L1-deficient mice showed decreased signs of podocyte injury and decreased proteinuria despite a comparable immunologic reaction to the injected anti-podocyte antibodies. Podocyte-specific proteins such as nephrin and podocin were stabilized and protein accumulation was decreased. UCH-L1-deficiency resulted in increased proteasomal capacity and activity in injured podocytes.

Conclusions: Podocyte-specific UCH-L1-deficiency protects podocytes from age-related degenerative changes and from immune complex nephritis through increased proteasomal capacity.

FR-PO347

Adhesion and Repulsion of Podocytes: Role of EphB-Receptors Eva Koenigshausen, Julius Hoffacker, Lukas Ludwig Peter Heimann, Nils Tim Haep, Magdalena Woznowski, Ivo Quack, Lars C. Rump, Lorenz Sellin. *Univ Hospital Duesseldorf.*

Background: Eph-receptor kinases mediate cell adhesion and repulsion at specialized cell contacts. Eph-receptor kinases bind to their cell-membrane bound ligands, the ephrines. Ephrinb1 and EphB4 have been localized at the slit diaphragm. The molecular function of the EphB1,2,3 receptors in podocytes is unknown so far. Proteinuria is a hallmark for

glomerular disease and results from disruption of the glomerular filter. The slit diaphragm is a specialized cell-cell contact between adjacent podocytes. Maintenances of the correct positioned, adjacent podocytes has not been well understood.

Methods: RNA was isolated from differentiated human podocytes and isolated murine glomeruli and PCR performed. Human podocytes were retrovirally transduced with EphB2-YFP or ephrinb1-CFP. EphB2-YFP and ephrinb1-CFP podocytes were differentiated in co-cultures and time lapse video imaging was performed. In addition, a co-culture of differentiated EphB2-YFP and ephrinb1-CFP cells was examined. To investigate the role of the intracellular domains of the EphB2 receptor and ephrinb1 ligand, truncated mutants of EphB2 (EphB2.DC-YFP) and ephrinb1 (ephrinb1.DC-CFP) were analyzed.

Results: Human podocytes as well as murine glomeruli express EphB1, 2 and 3 receptors. Co-cultures of differentiating EphB2-YFP and ephrinb1-CFP podocytes show repulsion between the two cell types. Transendocytosis (YFP particles in CFP cells and vice versa) occurs in both cell types during repulsion. The repulsion is dependent on the intracellular domain of EphB2 as EphB2.DC-YFP cells adhere to ephrinb1-CFP and ephrinb1.DC-CFP cells. However, repulsion is maintained in co-cultures of EphB2-YFP with ephrinb1.DC-CFP cells. Co-culture experiments of differentiated, confluent podocytes confirm the results presented above.

Conclusions: EphB2 receptors mediate podocyte repulsion upon binding to their ligand ephrinb1. The EphB2 receptor cytoplasmic domain seems to be crucial for repulsion. Maintaining the correct podocyte distance within the highly organised glomerular architecture is not been well understood. These cell culture data provide a promising concept of potential regulation of podocyte distance in vivo.

FR-PO348

Overexpression of the Splice Isoform VEGF165b Is Sufficient for Kidney Function when All VEGF Isoforms Are Depleted Megan Stevens, Chris R. Neal, Andy Salmon, David O. Bates, Steven J. Harper, Sebastian Oltean. *Univ of Bristol, United Kingdom.*

Background: Chronic kidney disease is associated with reduced VEGF-A expression. However, the role VEGF-A splice isoforms play in kidney physiology and pathology is unclear. Use of an alternative 3' splice site in the terminal exon of VEGF-A results in the expression of anti-angiogenic $VEGF_{165}b$. Previous studies suggest that $VEGF_{165}b$ is protective in renal function in diabetic rodent models. This study aimed to investigate whether constitutive podocyte over-expression of $VEGF_{165}b$ is able to rescue the injury phenotype seen in the inducible podocyte-specific VEGF-A KO mouse. The mechanism of action of $VEGF_{165}b$ within the glomeruli was also investigated.

Methods: Podocyte-specific VEGF-A KO was induced via doxycycline for 10-14 weeks in WT, VEGF-A KO and VEGF-A KO x neph-$VEGF_{165}b$ mice. In situ hybridization confirmed a knock-down of VEGF-A. The kidney functional phenotype was determined through the urinary albumin creatinine ratio (uACR) and measurement of glomerular water permeability. Electron microscopy was used to examine the ultra structure of the glomeruli, and immunofluorescence to determine the expression levels of podocyte and endothelial-specific proteins. Glomerular endothelial cells (GEnCs) in culture were used to determine the mechanism of action of $VEGF_{165}b$ through VEGFR-2.

Results: The $VEGF_{165}b$ isoform alone is sufficient to rescue the increase in albuminuria and glomerular water permeability in the context of progressive depletion of all VEGF-A isoforms. Ultra structural studies show glomerular basement membrane thickening and increased podocyte slit width in the VEGF-A KO mouse, with both being rescued in the $VEGF_{165}b$ over-expressors. $VEGF_{165}b$ also restores PECAM expression in GEnCs, and glomerular capillary circumference. Mechanistically, $VEGF_{165}b$ increases VEGFR-2 expression and phosphorylation both in vivo and in vitro. Furthermore, it down regulates genes involved in the migration and proliferation of GEnCs, which are otherwise up regulated by $VEGF_{165}$.

Conclusions: Our study indicates that VEGF-A splice isoform manipulation could be a novel therapeutic avenue in chronic glomerular disease.

Rituximab Prevents TNFα Induced Podocyte anb3 Integrin Activation Farah Leclercq, Christopher E. Pedigo, Alessia Fornoni, Sandra M. Merscher. *Katz Family Drug Discovery Center, Nephrology, Univ of Miami, FL.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is a disease characterized by podocyte damage and scarring of the glomeruli. FSGS accounts for up to 20% of end stage renal disease (ESRD) cases in the United States. Podocyte urokinase-receptor (uPAR) dependent aVb3 integrin activation and decreased glomerular sphingomyelin phosphodiesterase acid-like 3b (SMPDL3b) expression were described in glomerular biopsies from patients with FSGS. Circulating TNFα is increased in a fraction of patients with FSGS and anti-TNFα therapy has shown efficacy in a subset of patients with recurrent FSGS. We hypothesized that TNFα reduces SMPDL3b expression resulting in anb3 Integrin activation.

Methods: Differentiated human podocytes were cultured in the presence of TNFα (100ng/ml). Caspase 3 activity was determined in human podocytes. Protein and mRNA was isolated and the expression of key genes was investigated by Western blot analysis and quantitative real time PCR. Rituximab was used at the dose of 100 ug/mL.

Results: TNFα treatment of human podocytes significantly reduced SMPDL3b expression ($p<0.05$), increased uPAR expression ($p<0.05$) and b3 integrin activation ($p<0.05$). TNFα treatment induced caspase 3 activity, which was prevented by preserving SMPDL3b expression with Rituximab ($p<0.05$) or by inhibiting b3 integrin activation with cycloRGD ($p<0.05$). Likewise, SMPDL3b overexpressing podocytes were protected from TNFα induced b3 integrin activation. Injection of recombinant TNFα in mice led to increased glomerular uPAR mRNA expression ($p<0.05$) and caused albuminuria ($p<0.05$), which was significantly attenuated with Rituximab ($p<0.05$).

Conclusions: TNFα decreases SMPDL3b expression, increases uPAR expression and activates b3 integrin signaling leading to podocyte injury and apoptosis. Our data suggest that treatments targeting the TNFα–SMPDL3b-b3 integrin axis may prevent podocyte injury in FSGS.

Deletion of the Major Soluble Flt1 Isoform from Mice Reveals New Vegf Decoy Variants Biao Li,[2] Tuncer Onay,[1] Chengjin Li,[2] Vera Eremina,[2] Susan E. Quaggin.[1,2] *[1]Feinberg Cardiovascular Research Inst; [2]Lunenfeld-Tanenbaum Research Inst.*

Background: sVEGFR1 (sflt1) is an alternative splicing product of VEGFR1 (flt1) gene. Both flt1 and sflt1 can function as "decoy receptors" for VEGF. sflt1 plays a key role in maintaining avascularity of the cornea, and increased circulating levels of sflt1 are linked to preeclampsia. Moreover, deletion of flt1 from mouse podocytes results in proteinuria at 6 weeks of age, while deletion of the kinase signaling domain of this receptor alone results in no renal phenotype. *In vitro* studies showed that sflt1 can induce formation of foot process-like structures in human podocytes. We hypothesize that sflt1 regulates podocyte cytoskeletal dynamics and glomerular barrier function by titrating local glomerular Vegf levels.

Methods: To determine function of the soluble variant of Flt1 in the glomerulus, we generated a conditional KO model for the single sFlt1 (sFlt1 cKO) isoform reported in mice (removal of intron 13). Renal phenotype was examined by evaluating kidney function and histology. qPCR and Northern blot were used to identify splice variants of flt1; 3'RACE was used to clone the spliced genes. Proteins of splice variants were generated by BacMam system.

Results: We generated sflt1 cKO mice, and confirmed the deletion of Flt1 intron 13 using Southern blot. Surprisingly, it did not result in any overt kidney phenotype by 6 months of age. Northern blot and Western blot analyses revealed the existence of a major compensatory isoform, previously reported as human-specific. We also confirmed the existence of 17 new sFlt1 isoforms in RNA isolated from mice and 12 from human preeclamptic placentas.

Conclusions: We report a large number of novel, soluble flt1 isoforms in both mouse and human placenta samples. We posit that the presence of these isoforms compensates for the loss of sflt1 in our transgenic model. The functions of these isoforms warrant further investigation and may provide insight into regulation of Vegf levels, podocyte function and preeclampsia.

Polarity Signaling at the Kidney Filtration Barrier: Questioning the Function of Par3A Sybille Köhler,[1,2] Markus M. Rinschen,[1,2] Carien M. Niessen,[4] Wilhelm Bloch,[3] Bernhard Schermer,[1,2] Thomas Benzing,[1,2] Paul T. Brinkkoetter.[1,2] *[1]Dept II of Internal Medicine and Center for Molecular Medicine, Univ Hospital Cologne, Germany; [2]Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), Univ of Cologne, Germany; [3]Dept of Molecular and Cellular Sport Medicine, German Sport Univ Cologne, Germany; [4]Dept of Dermatology and CECAD Cologne, Univ of Cologne, Germany.*

Background: The slit diaphragm (SD) represents the only cell-cell contact in-between neighbouring podocytes. Classical adherence as well as tight junction proteins are part of this protein-protein supercomplex including ZO-1, occludin, catenins and cadherins. Polarity signaling is critical to maintain the SD complex as the Par3/Par6/aPKC complex clusters at the SD via direct interaction of Par3 with neph/nephrin via its PDZ-domains.

Methods: To understand the role of the Par3 proteins at the slit diaphragm, we generated a novel podocyte specific Par3A knockout mouse model where exon 6 is flanked by loxP sites. Following podocin:cre mediated recombination expression of all known Par3A isoforms should be abrogated. We validated cre recombinase efficiency, lack of Par3A mRNA and protein expression by qPCR from isolated primary podocytes as well as by immunofluorescence stainings on renal sections.

Results: Mice were born in predicted Mendelian frequency. $Par3A^{pko}$ mutants appeared as healthy as wt $Par3A^{flox/flox}$ mice at birth and did not show any signs of disease in their later life. Even challenging $Par3A^{pko}$ mice with the albumin overload model did not result in an overt glomerular phenotype. Therefore, we performed additional immunoprecipitation experiments for aPKCiota out of immortalized mouse podocytes and carried out nLC-MS/MS analysis to identify the aPKCiota podocyte interactome. Interestingly, the most abundant aPKCiota interacting proteins were Par6 and Lgl1/2.

Conclusions: Our results challenge the current view of the aPKC/Par3/Par6 complex and its role at the slit diaphragm. In contrast to tight junctions where aPKC-signaling depends on clustering by Par3A, its role at the SD is independent of Par3A. Here Lgl1/2 seem to be the predominant interactors clustering aPKC/Par6 at the SD.

FR-PO352

Focal Segmental Glomerulosclerosis (FSGS) Permeability Factor (FSPF) Interacts with Glomerular Filtration Barrier Through Glycoconjugates

Ram Sharma,[1] Ellen T. McCarthy,[2] Tarak Srivastava,[3] Virginia J. Savin,[1] Mukut Sharma.[1] *[1]Renal Research, KC VA Medical Center- MBRF, Kansas City, MO; [2]Kidney Inst, KU Medical Center, Kansas City, KS; [3]Renal Div, UMKC Children's Mercy Hospital, Kansas City, MO.*

Background: Galactose (Gal) blocks the FSGS serum-induced increase in *in vitro* glomerular albumin permeability (P_{alb}) (*Trans Res* 2008, 151:288-292) and decreases proteinuria in some patients with recurrent FSGS (*NDT* 2009, 24:2938-2940). Thus, the interaction of FSPF with glomerular cell surface glycoconjugates may play an essential role in its effect on the filtration barrier.

Methods: We selected sugars and lectins to model the interaction between glomerular glycoconjugates and FSPF. We used, (i) affinity techniques to evaluate the binding of FSPF with immobilized sugars (ii) immobilized neuraminidase to remove sialic acid to assess its significance in FSPF-induced increase in P_{alb} and (iii) Gal/N-acetyl Gal (GalNac)-specific lectins to determine their effect on P_{alb} as FSPF mimetics.

Results: Plasma FSPF activity was retained by immobilized Gal, GalNac or galactosamine. Gal dose-dependently blocked FSPF-induced increase in P_{alb} (10^{-9}-10^{-6} M) and partially reversed the effect of FSPF on P_{alb} ($p<0.01$). In contrast, glucose, glucosamine or mannose did not interact with FSPF. Removal of sialic acid by neuraminidase diminished the FSPF-induced increase in P_{alb}. We screened twenty Gal/GalNac-specific lectins as potential mimetics of FSPF. Only *Dolichos biflorus* agglutinin (DBA, 10 mg/mL) and *Helix pomatia* lectin (10 mg/mL) increased P_{alb} to 0.65 and 0.55, respectively ($p<0.001$). The increases in P_{alb}, like that induced by FSPF were blocked by Gal (100 μM) ($p<0.001$).

Conclusions: One or more carbohydrate-recognizing domains of FSPF participate in its interaction with specific sugar(s) of glomerular cells resulting in altered filtration barrier function. Our novel findings regarding the affinity of FSPF for select sugars, the loss of activity after removal of sialic acid and the direct effect of certain lectins on barrier function provide new information regarding the molecular composition of FSPF and its interaction with glomerular proteins/glycolipids.

FR-PO353

EPB41l5 Is a Critical Regulator of the Kidney Filtration Barrier

Christoph Schell,[1] Martina Suhm,[1] Manuel Rogg,[1] Martin Helmstaedter,[1] Mariko Hirano-Kobayashi,[2] Tobias B. Huber.[1] *[1]Dept of Nephrology, Univ Medical Center Freiburg, Freiburg, Baden-Württemberg, Germany; [2]Laboratory for Vertebrate Body Plan, Center for Developmental Biology - RIKEN, Kobe, Kobe, Japan.*

Background: Podocyte loss represents the final common pathway of various glomerular pathologies. Hence, tightly regulated adhesion towards the glomerular basement membrane is a fundamental biological process of glomerular podocytes.

Methods: Based on podocyte single cell isolation and a mass-spec candidate approach the composition of podocyte focal adhesions was resolved. Combining a drosophila nephrocyte model with a newly generated conditional mouse model and various high resolution microscopy techniques (TEM, STORM) the candidate protein EPB41l5 was analyzed.

Results: Knockdown of the Epb41l5 homolog Yurt in drosophila nephrocytes resulted in mis-localization of slit membranes and defective endocytic capacity. Evaluation of a conditional knockout model revealed a rapid loss of podocytes implicating deregulated adhesion of podocytes. Employing immunogold electron microscopy and STORM super resolution microscopy EPB41l5 was clearly localized towards the basal compartment of podocytes, in close proximity to INTEGRIN-beta1. Further functional experiments revealed that loss of EPB41l5 resulted in decreased activation of INTEGRIN-beta 1, reflected by altered migratory behavior of primary podocytes.

Conclusions: Our findings indicate that EPB41l5 is a highly conserved, specific regulator of podocyte adhesion by modulating focal adhesion composition and function. Future studies will need to clarify its potential implications in genetic and acquired glomerular pathologies.

FR-PO354

The Effect of Anti-PLA2R Autoantibodies on Human Podocytes *In Vitro*

Maryline Fresquet,[1] Rachel Lennon,[1] Paul E. Brenchley.[2] *[1]Wellcome Trust Centre for Cell-Matrix Research, Univ of Manchester, Manchester, United Kingdom; [2]Inst of Cardiovascular Sciences, Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: PLA_2R was identified as a major target antigen in idiopathic membranous nephropathy. 70% of patients have circulating autoantibodies which bind this receptor on the podocyte leading to immune complex deposition in the glomerular basement membrane. We recently identified the major epitope on PLA_2R recognised by anti-PLA_2R autoantibodies, produced the first 3D model of PLA_2R domains and demonstrated that autoantibodies are of high affinity. We seek to understand if affinity-pure anti-PLA_2R alone in the absence of complement can modulate podocyte function.

Methods: We prepared affinity purified human anti-PLA_2R (91% IgG4, 9% IgG2) and assessed podocyte morphology following autoantibody treatment using immunofluorescence staining of actin and measurement of cell surface area and circularity. Integrity of the filtration barrier was assessed by Electric Cell-substrate Impedance Sensing and the response of a confluent monolayer of differentiated podocytes to 10mg/ml purified human anti-PLA2R and purified human IgG was measured. Cell apoptosis was determined by cleaved caspase-3 staining in podocytes and oxidative stress was measured with CellROX reagent in differentiated podocytes challenged with the autoantibody.

Results: We have developed an *in vitro* podocyte model to define mechanisms of anti-PLA_2R effects on cell morphology and function. Purified anti-PLA_2R altered podocyte shape, with rounding and loss of actin stress fibres within 24 hours. Integrity of a confluent podocyte monolayer was significantly reduced at 72 hours by anti-PLA_2R but not by the IgG control. Within 30 minutes of anti-PLA_2R treatment, there was evidence of caspase-3 cleavage in podocytes peaking at 6 hours promoting apoptosis. In the same time frame anti-PLA_2R induced free radical generation ($P<0.0001$, treated *v.* untreated), triggering oxidative stress which could be neutralised using a scavenger.

Conclusions: Anti-PLA_2R in the absence of complement activation modulates podocyte cell biology by inducing changes in cell shape and monolayer permeability, activation of free radical production and apoptosis.

FR-PO355

Deletion of the Ste20-Like Kinase, SLK, in Podocytes Induces Injury

Andrey V. Cybulsky,[1] Elena Torban,[1] Joan Papillon,[1] Julie Guillemette,[1] Natalya Belkina.[2] *[1]Medicine, McGill Univ, Montreal, QC, Canada; [2]NIH, Bethesda, MD.*

Background: SLK is essential for embryonic development, and may play a key role in wound healing, tumor growth and metastasis. Expression and activation of SLK is increased during recovery from ischemic acute kidney injury. Overexpression of SLK in glomerular epithelial cells/podocytes in vivo induces injury and proteinuria. Conversely, insufficient SLK expression leads to abnormalities in cell adhesion, spreading, and motility. Tight regulation of SLK expression thus appears to be critical for normal renal structure and function. We address the functional role of SLK in podocytes.

Methods: Podocyte-specific SLK knockout (KO) mice were produced by breeding mice with loxP sites surrounding exons 4-7 with podocin (NPHS2)-Cre mice. LoxP-mediated excision results in deletion of the kinase domain. Deletion of SLK exons 4-7 in glomeruli was confirmed with PCR.

Results: Podocyte-specific deletion of SLK resulted in albuminuria at 4-5 months of age in male mice, and 8-9 months in female mice, which persisted for up to 13 months (albumin/creatinine in KO was 2-3-fold above control). At 11-12 months, KO mice did not show renal histologic abnormalities by light microscopy, and glomerular area of KO was comparable to control. However, by electron microscopy, KO mice showed focal foot process effacement and microvillous transformation of podocyte plasma membranes. Mean foot process width was ~2-fold greater in KO, compared to control. By immunofluorescence microscopy, WT1-positive cells were reduced by 35% in KO mice compared to control, and staining for nephrin and podocalyxin was reduced in KO mice by 20-30%. SLK is reported to phosphorylate ezrin. Staining for phospho-ezrin/radixin/moesin (ERM) was reduced by 20% in KO glomeruli, in keeping with reduced SLK catalytic activity in glomeruli; however, tubular phospho-ERM staining was comparable in KO and control.

Conclusions: Podocyte-specific deletion of SLK leads to albuminuria, loss of podocytes and morphologic evidence of podocyte injury. Thus, SLK is essential to the maintenance of podocyte integrity as mice age. The mechanism may, at least in part, relate to ezrin phosphorylation and cytoskeletal integrity.

A Podocyte-Specific Knockout of the DNA Repair Gene Ercc1 Leads to Proteinuria and Focal Segmental Glomerulosclerosis

Fabian Braun,[1] Roman Aaron Akbar,[1] Björn Schumacher,[2] Wilhelm Bloch,[3] Bernhard Schermer,[1,2] Thomas Benzing,[1,2] Christine E. Kurschat.[1,2] *[1]Nephrology, Univ Hospital Cologne, Cologne, Germany; [2]CECAD, Univ Hospital Cologne, Cologne, Germany; [3]German Sport Univ Cologne, Cologne, Germany.*

Background: The prevention and therapy of aging-related diseases will become a major health problem. Among elderly patients mild to severe impairment of kidney function is common. Models to study renal aging have not been established yet.In a previous study, we identified a progeria mouse model of Ercc1-deficiency to exhibit expression profiles similar to those of glomerular aging in wt mice. Ercc1 is involved in nucleotide excision repair, facilitating 5' incision around bulky DNA lesions. In humans, the lack of Ercc1 leads to a progeria phenotype. Thus, a podocyte-specific knockout of Ercc1 may help us gain new insights into glomerular and podocyte aging processes.

Methods: $Ercc1^{flox/flox}$ mice were bred in a mixed CD1/FVB background with CD1 mice expressing Cre recombinase under the podocin promoter. We analyzed weight, urine and serum of animals at 7, 9, 11 and 13 weeks of age. Kidneys were fresh-frozen in OCT, fixed in paraformaldehyde and embedded in paraffin or prepared for electron microscopy.

Results: $Ercc1^{pko}$ mice are born in normal mendelian ratios and show no developmental abnormalities. We detected an onset of proteinuria at week 8 to 10. Animals maintain a normal weight curve compared to controls until week 11 to 18. 7 week old kidneys show no morphological changes in light or electron microscopy. Male and female mice develop foot process effacement and focal segmental glomerular sclerosis at 9 weeks of age. This phenotype is aggravated by week 11. PAS staining of end-stage kidneys reveals sclerosed glomeruli, interstitial fibrosis with tubular atrophy and tubular protein casts. We observed an increase in DNA damage shown by positive pH2A.X staining in glomerular nuclei at week 11.

Conclusions: Our study reveals a critical role for nucleotide excision repair in murine podocytes. This severe and early phenotype underlines the importance of podocyte DNA maintenance in these postmitotic cells. In ongoing studies we will characterize the role of Ercc1 in a podocyte cell culture model.

Mice Heterozygous for Rac1 in the Podocyte Are Protected against Nephrotoxic Serum Nephritis-induced Albuminuria, but Knockout Mice Are Not

Stephanie Wylie,[1] Jinghui Luo,[1] Yingbao Yang,[1] David J. Salant,[2] Jeffrey B. Hodgin.[1] *[1]Pathology, Univ of Michigan, Ann Arbor, MI; [2]Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: Podocyte injury, either by genetic or acquired abnormalities, can lead to progressive proteinuria and glomerulosclerosis. Current treatments are not designed to specifically target the podocyte but are used for broader immunotherapeutic or anti-inflammatory properties, thus podocyte-targeted therapies are needed. Rac1, a member of the Rho GTPase family, has been suggested as a therapeutic target for podocyte injury. However we previously demonstrated that podocyte-specific Rac1 knockout mice have exacerbated albuminuria with a hypertensive injury model. We hypothesize that partial reduction of podocyte Rac1 is protective.

Methods: We employed the nephrotoxic serum (NTS) nephritis model, which causes predominant podocyte injury and high-grade proteinuria without appreciable inflammation, in wild-type (WT), podoRac1-KO (podoRac1-KO), and podocyte-specific Rac1 heterozygous mice (podoRac1-HET). A separate group of NTS treated WT mice were given EHT1864 (40mg/kg), a Rac inhibitor. Mice were injected with NTS (1.5 mg/kg body weight) (n=8-10 mice per group) and placed in metabolic cages for 1 or 2 days for daily urine collection. Urine albumin was measured by SDS-PAGE gel with standard curve, normalized by urine creatinine.

Results: NTS treatment resulted in robust albuminuria in wild-type mice on days 1 and 2 with albumin-to-creatinine ratios (ACR) of 400-500 ug/mg. However, podoRac1-KO mice showed an equally robust albuminuric response on day 1, but less on day 2 compared to wild-type,suggesting accelerated recovery. In contrast, NTS treated podoRac1-HET mice demonstrated nearly 70% reduction in ACR compared to wild-type (130 versus 390 ug/mg, $P<0.01$). The Rac inhibitor EHT1864 was equally effective.

Conclusions: These results demonstrate that a partial reduction in Rac1 activity, through genetic or pharmacologic inhibition, provides a protective effect against NTS-mediated podocyte injury, whereas Rac1 deletion is not beneficial. Our findings should help guide the development and assessment of Rac1 inhibitors to target podocyte injury.

The Ectodomain of Syndecan-4 Increases Surface Expression of Podocyte TRPC6 Channels: An Essential Role for Integrin Signaling

Eunyoung Kim, Hila Roshanravan, Stuart E. Dryer. *Biology and Biochemistry, Univ of Houston, Houston, TX.*

Background: Excessive activation of podocyte TRPC6 channels has been implicated in glomerular diseases. Syndecan-4 (Sdc-4) is a type-1 single-pass proteoglycan that can be cleaved to produce a soluble product capable of paracrine and autocrine signaling. A previous study (1) showed that the Sdc-4 core protein increases the surface expression of TRPC6 in podocytes. Here we show that the Sdc-4 ectodomain can also modulate TRPC6 channels and we describe some of the pathways that surround this effect.

Methods: Cell surface expression of TRPC6 was monitored using surface biotinylation assays and whole-cell patch clamp recordings from cultured mouse podocytes. Signaling pathways were examined using assays for activated components and selective inhibitors. Protein interactions were examined by co-immunoprecipitation and confocal microscopy.

Results: We have confirmed previous studies showing effects of over-expression and knockdown of Sdc-4 core protein on podocyte TRPC6 (1). In addition, exposing podocytes to Sdc-4 ectodomain caused an increase in the surface abundance of TRPC6, accompanied by an increase in cationic currents evoked by diacylglycerol (OAG). Sdc-4 ectodomain increased the generation of reactive oxygen species (ROS) and effects of Sdc-4 on TRPC6 were blocked by the ROS quencher TEMPOL. Exposure to Sdc-4 ectodomain caused activation of NFATc1 and Rac1, inhibition of RhoA, and increased the total abundance of b3-integrin. However, Sdc-4 ectodomain effects on surface expression of TRPC6 persisted after inhibition of calcineurin or NFAT. The Sdc-4 core protein immunoprecipitated and co-localized with b3-integrin in podocytes. Moreover, effects of Sdc-4 ectodomain were inhibited by cilengitide, an inhibitor of outside-in signaling through av-containing integrins. Exposure to TNF caused a marked increase in shedding of Sdc-4 ectodomain from podocytes into the surrounding medium. This also occurred after over-expression of Sdc-4 core protein.

Conclusions: Locally produced Sdc-4 ectodomain may play a role in regulating podocyte TRPC6 channels and may contribute to glomerular pathology. (1) Liu et al. (2012). Atherioscler Thromb Vasc Biol 32: 378-385.

Regulation of Fascin-1 by Mechanical Stress in Podocytes

Felix Kliewe,[1] Christian Scharf,[2] Sandra Schordan,[1] Elisabeth Rumpel,[1] Katrin Darm,[2] Silke Vogelgesang,[3] Kerstin U. Amann,[4] Henny Wegner,[1] Jürgen Giebel,[1] Karlhans Endlich,[1] Nicole Endlich.[1] *[1]Anatomy and Cell Biology, Univ Medicine of Greifswald, Greifswald, Germany; [2]ENT, Univ Medicine of Greifswald, Germany; [3]Pathology, Univ Medicine of Greifswald, Germany; [4]Nephropathology, Univ Hospital of Erlangen, Germany.*

Background: Glomerular hypertension causes glomerulosclerosis via the loss of podocytes, which are challenged by an increased mechanical load. We and others have demonstrated that podocytes are mechanosensitive cells. However, the response of podocytes to stretch remains incompletely understood.

Methods: Using 2D fluorescence difference gel electrophoresis (2D DIGE), we analyzed the proteome of cells of our mouse podocyte cell line that were cultured on flexible membranes with or without cyclic biaxial mechanical stress (0.5 Hz, 5% linear strain, 3 d).

Results: Mechanical stress profoundly altered the podocyte proteome. Several spots containing the actin-bundling protein fascin-1 were differentially regulated by mechanical stress. By immunofluorescence, fascin-1 was found to colocalize with nephrin in mouse kidney sections. The presence of fascin-1 in foot processes was confirmed by immunoelectron microscopy. Knockdown of fascin-1 in cultured podocytes increased the cell loss in response to mechanical stress. The mRNA levels of fascin-1 were not affected by mechanical stress. However, mechanical stress resulted in an almost complete dephosphorylation of fascin-1. It is known that phosphorylation at Ser-39 regulates the bundling activity of fascin-1, e.g. required for filopodia formation. Podocytes expressing wild type GFP-fascin-1 and non-phosphorylatable GFP-fascin-1-S39A showed marked filopodia formation, being absent in podocytes expressing phosphomimetic GFP-fascin-1-S39D. Finally, the immunofluorescence signal of phosphorylated fascin-1 was strongly reduced in glomeruli of patients with diabetic nephropathy as compared to glomeruli of healthy controls.

Conclusions: In summary, mechanical stress dephosphorylates fascin-1 in podocytes thereby increasing the actin-bundling activity of fascin-1. Fascin-1 may play an important role in the adaptation of podocytes to mechanical stress.

Deletion of the Vps34 Downstream Effector PIKfyve Establishes Milder Endocytic Dysfunction in Healthy Glomerular Podocytes Compared to Proximal Tubular Cells

Madhusudan Venkatareddy, Rakesh Verma, Sanjeevkumar R. Patel, Puneet Garg. *Internal Medicine/ Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: The mechanisms by which the glomerular filtration barrier prevents the loss of large macromolecules and at the same time maintain the filter remain poorly understood. Recent studies have proposed that podocytes play an active role in both endocytosis of filtered macromolecules and maintaining the filtration barrier.

Methods: We generated podocyte and proximal tubular specific deletion of PIKfyve using the cre-loxP system. Indirect IF and immune EM was used to assess the endocytic pathways.

Results: Deletion of a key endosomal trafficking regulator, the class III phosphoinositol 3-kinase or Vps34 in podocytes results in aberrant endosomal membrane morphology and podocyte dysfunction. We recently demonstrated that the vacuolation phenotype in cultured Vps34-deleted podocytes is due to the absence of a substrate for the Vps34 downstream effector PIKfyve. PIKfyve is a Fyve finger domain containing phosphoinositide 5-kinase that phosphorylates Vps34-generated phosphatidylinositol (PtdIns)3P to produce PtdIns(3,5)P2. PIKfyve perturbation and PtdIns(3,5)P2 reduction have been shown to result in massive membrane vacuolation along the endosomal system. We show here that deletion of PIKfyve in endocytically active proximal tubular cells resulted in the development of large cytoplasmic vacuoles that appear as a result of arrested endocytic traffic progression at a late-endosome stage. In contrast, deletion of PIKfyve in podocytes did not alter significantly the endosomal morphology even in aged, 18-month-old mice. However upon culturing, the PIKfyve-deleted podocytes obtained from the knockout mouse developed massive cytoplasmic vacuoles. Measurement of phosphoinositides using HPLC shows reduction of both PtdIns(3,5)P2 and PtdIns(5)P in PIKfyve deleted podocytes *in vitro* confirming reduced PIKfyve enzymatic activity following deletion. Using double fluorescent mtmG mouse we were able to confirm Cre-mediated gene deletion in both podocytes and proximal tubular cells *in vivo*.

Conclusions: In summary, these data suggest that healthy podocytes have a low level of endocytic flux *in vivo*.

FR-PO361

Albumin-Induced Podocyte Injury Can Be Endocytosis-Independent
Shipra Agrawal,[1] Xiaojing Nie,[1] Tetsuya Kitao,[1] Melinda A. Chanley,[1] William E. Smoyer.[1,2] *[1]Clinical and Translational Research, Research Inst at Nationwide Childrens Hospital, Columbus, OH; [2]Pediatrics, Ohio State Univ, Columbus, OH.*

Background: Endocytosis plays a crucial role in podocytes in nephrotic syndrome, wherein podocytes are exposed to serum levels of albumin. We have previously reported an association between podocyte exposure to albumin (and its associated factors) and proteinuria, cell injury and induction of pro-inflammatory genes. We thus hypothesized that albumin-induced podocyte injury can also be partially endocytosis independent.

Methods: Endocytosis was analyzed by fluorescence microscopy and fluorometry in cultured differentiated podocytes at varying temperatures and times and in the absence and presence of inhibitors of clathrin- and caveolae-mediated endocytosis. Cells were analyzed for viability, activation of major kinases (p38, ERK1/2, JNK, MK2), and expression of pro-inflammatory, heat shock, and glucocorticoid-regulated genes.

Results: Endocytosis was detected in podocytes at 37°C, but not at 4°C, and was attenuated by inhibitors for both clathrin- and caveolae-mediated endocytosis. Inhibition of endocytosis, however, did not correlate with reductions in kinase activation or pro-inflammatory gene induction. While albumin exposure resulted in lower endocytosis in murine vs. human podocytes, murine cells activated kinases, induced pro-inflammatory genes and exhibited cell death more than human podocytes.

Conclusions: Inhibition of both clathrin- and caveolae-mediated albumin endocytosis did not correlate with activation of kinases and induction of pro-inflammatory genes in podocytes. Moreover, disparate responses were identified in human vs. mouse podocytes with regard to albumin endocytosis, cell injury, kinase activation, and pro-inflammatory gene induction. Taken together, our data suggest that although podocytes endocytose albumin in both clathrin- and caveoloe-mediated manners, albumin-induced podocyte injury can occur in an endocytosis-independent manner.

Genome-Modified Pluripotent Stem Cells Reveal a Critical Role for Podocalyxin in Human Podocyte Morphogenesis
Benjamin S. Freedman,[1,2,3] Craig R. Brooks,[1,2] Jing Zhou,[1,2] Joseph V. Bonventre.[1,2] *[1]Brigham and Women's Hospital; [2]Harvard Medical School; [3]Univ of Washington School of Medicine.*

Background: Human pluripotent stem cells (hPSCs) can self-renew extensively and differentiate into diverse tissues. We investigated the potential of hPSCs to differentiate into kidney podocytes, and used CRISPR/Cas9 gene editing to explore the function of podocalyxin, an apical sialomucin altered in glomerular disease states.

Methods: Cas9 nuclease and guide RNAs targeting *PODXL* were transfected into hPSCs. *PODXL*$^{-/-}$ clones were identified by chromatogram and immunoblot analysis. hPSCs were differentiated stepwise with growth factors into kidney progenitor cells (SIX2^{+}PAX2^{+}) and subsequently kidney tubular organoids. Podocyte marker expression was investigated by confocal microscopy in unmodified or *PODXL*$^{-/-}$ organoids of otherwise identical genetic background.

Results: In kidney organoids, podocyte markers including podocalyxin, WT1, and synaptopodin were strongly expressed in tight clusters of spherical cells, which resembled capillary loop stage podocytes by electron microscopy. These cells did not react with LTL, but arose in capsule-like termini in LTL^{+}LRP^{+} proximal tubules. Podocalyxin coated the plasma membrane, whereas ZO-1, synaptopodin, and β-catenin co-localized in linear tracks between adjacent cells. *PODXL*$^{-/-}$ hPSCs differentiated into similar clusters, which did not express podocalyxin. In *PODXL*$^{-/-}$ clusters, ZO-1, synaptopodin, and β-catenin failed to organize into linear tracks, instead migrating laterally in a diffuse expression pattern. This correlated with a ~ 40 % decrease in intercellular distance between nuclei, compared to unmodified isogenic controls.

Conclusions: hPSCs can differentiate into cells resembling immature podocytes. Podocalyxin is dispensable for podocyte specification, but is required for proper organization of junctional complexes and podocyte spacing. Our findings suggest a functional role for podocalyxin in the establishment of human podocyte architecture. Genome-modified hPSC-podocytes present a new tool for investigating human podocytes, with potential for 'disease in a dish' models and therapeutic screens.

Molecular Targeting of Neph1 Signaling: A Therapeutic Approach to Protect Podocyte Injury
Deepak Nihalani,[1] Ehtesham Arif,[3] Fnu Ashish,[2] Lawrence B. Holzman.[1] *[1]Medicine, Univ of Pennsylvania, Phladelphia, PA; [2]Proteomics, Inst of Microbial Technology, Chandigarh, India; [3]Medicine, Temple Univ, Philadelphia, PA.*

Background: Glomerular injuries that induce podocyte dysfunction are the leading causes of renal malfunction. Podocyte proteins Nephrin and Neph1 are essential components of the glomerular filtration barrier and signaling from these proteins is involved in maintaining podocytes structure and function. Thus understanding the mechanisms that regulate signaling and organization of these proteins are therapeutically valuable.

Methods: This study presents a novel hypothesis that attenuating Nephrin and Neph1 signaling is therapeutically significant in protecting podocytes from injury. Consistent with this hypothesis, using a unique protein transduction approach, we recently demonstrated that inhibiting Neph1 signaling protected podocytes from injury. Since we first reported the solution structures of Neph1CD and ZO-1-PDZ1, we used them to identify novel molecules or compounds that can specifically bind Neph1 and target its interactions.

Results: Using a novel approach of targeting protein-protein interaction, we identified many potential molecules and to test the proof of principle and the validity of this approach, one of the compounds ID (isodesmosine) was commercially procured and investigated. Biochemical experiments suggested that addition of ID under in vitro and in vivo conditions significantly increased and stabilized the interaction between Neph1 and ZO-1. As a consequence, induction of glomerular injury by PAN (puromycinaminonucleoside) did not alter the distribution of Neph1 at the podocyte cell membrane; in addition, these cells resisted injury induced changes in their actin cytoskeleton. Furthermore, using an *in vivo* zebrafish model system, we demonstrated that pre-treatment with ID rescued zebrafish from adriamycin induced toxicity and preserved their renal filtration system.

Conclusions: Collectively, this is the first study that provides compelling initial evidence that molecular approaches can be used to directly target slit diaphragm proteins to prevent podocyte damage.

Extracorporeal Mesenchymal Stromal Cell Therapy for Critical Care
Biju Parekkadan. *Surgery (Bioengineering), Harvard Medical School, Massachusetts General Hospital, Boston, MA.*

Background: Human mesenchymal stromal cells (MSCs) metabolize and secrete anti-inflammatory and regenerative factors that can be of systemic benefit to acute, critical injury. When transplanted MSCs are limited in dose and rapidly cleared by the body, therefore prohibiting controlled exposure to this cell therapy. We have developed a bioreactor technology to maintain MSC viability at high fidelity and continuously deliver secreted factors into the blood stream in a clinical setting.

Methods: MSCs were integrated into hollow-fiber bioreactor devices whereby the cells, separated by a permeable membrane, can directly and dynamically provide systemic therapy without entering the body. We present a human scale prototype of the technology that has shown sustained cell viability and function throughout cGMP manufacturing in preparation for a Phase I human trial set to begin in 2015.

Results: The presentation will also report encouraging *in vivo* therapeutic trials in a large animal (canine) model of ischemic acute kidney injury (AKI) where 91% of animals survived compared to 50-60% in control arms. Pharmacological analysis of this bioreactor technology *in vivo* allowed for an unprecedented look at MSC function during product use and verified potency that is unattainable by conventional intravascular delivery of MSCs.

Conclusions: A combined approach to optimize MSC therapy that employs pharmacology principles and cell delivery strategies will be essential to translating this cell therapy product to humans for AKI and other critical organ dysfunction syndromes.

Extracorporeal Diffusive Clearance of Silicon Nanopore Membranes in a Pumpless Porcine Blood Circuit
Steven Kim,[1] Willieford Moses,[2] Jaehyun Park,[3] Clarence Chow,[3] Charles Blaha,[3,4] Zohora Iqbal,[3] Rishi Kant,[3] Benjamin Chui,[5] Ken Goldman,[6] William Henry Fissell,[7,4] Shuvo Roy.[3,4] *[1]Nephrology, UCSF; [2]Surgery, UCSF; [3]Bioengineering, UCSF; [4]Silicon Kidney, LLC; [5]Ben Chui Consulting; [6]H-Cubed; [7]Nephrology & Hypertension, Vanderbilt Univ.*

Background: Silicon nanopore membranes designed for hemofiltration (HF-SNM) have demonstrated increased permeability compared to polymer membranes. Previously, we reported in-vitro data showing a 3-fold improvement in diffusive clearance using SNM optimized for diffusion (HD-SNM). Here we test the diffusive clearance of HD-SNM vs HF-SNM in an extracorporeal porcine model without a blood pump.

Methods: A microelectromechanical systems fabrication technique was used to decrease the SNM thickness (HD-SNM 100µm vs HF-SNM 400µm). Polyethylene glycol coated HD-SNM (n=3) and HF-SNM (n=3) with sub-10nm pore sizes were tested in a single channel flow circuit (h=1mm). Vascular access was obtained by placing tunneled catheters within the carotid artery and jugular vein of healthy ~50kg pigs. Blood flow was achieved via the arterial-venous pressure differential (35-120ml/min). Dialysate was recirculated in a counter-current fashion (30ml) and flow rates were adjusted to ensure 0 transmembrane pressure. Dialysate creatinine concentration was measured hourly and serum creatinine was measured at time 0 and 6 hours. The pore size of each SNM was measured before and after blood exposure using hydraulic permeability.

Results: Blood flow was achieved using only the arterial-venous pressures differential with <5mmHg pressure drop. The average plasma creatinine concentration was 1.38±0.1mg/dL. The creatinine clearance was 37.2±3.9ml/min/m^2 (HF-SNM) vs 126.0±27.1ml/min/m^2 (HD-SNM) at 92.5±36.6ml/min. There was no detectable albumin transport into the dialysate. The HD-SNM maintained mechanical integrity at over 250mmHg in-vitro. The pore size change following blood exposure was 1.4±2.3nm vs 1.9±1.2nm for HF-SNM and HD-SNM, respectively.

Conclusions: This study demonstrates the successful transport of creatinine in an extracorporeal circuit without a blood pump. We also showed a ~3-fold improvement in diffusive clearance of creatinine using HD-SNM in a blood circuit.

Hemofilter Design Based on Computational Simulations of Pulsatile Flow Amanda Buck,[1] Joseph J. Groszek,[2] Clark David Kensinger,[3] Daniel Colvin,[1] Shuvo Roy,[4] William Henry Fissell.[2] *[1]Dept of Radiology and Radiological Sciences, Vanderbilt Univ; [2]Div of Nephrology and Hypertension, Vanderbilt Univ; [3]Dept of Surgery, Vanderbilt Univ; [4]Dept of Bioengineering and Therapeutic Sciences, Univ of California San Francisco.*

Background: In the US, the ratio of patients with end stage renal disease (ESRD) on dialysis to annual kidney transplants for ESRD is 20:1 (USRDS 2014 Annual Data Report), underscoring the grave need for an artificial kidney alternative. Hypothesis: For the development of a hemofiltration device, computational fluid dynamics (CFD) simulations can predict potentially thrombogenic zones [e.g. low and high wall shear stress (WSS) areas, associated with stasis and shear induced cell damage, respectively] and can be used to refine device design to minimize such areas.

Methods: CFD simulations of pulsatile blood flow through a prototype hemofilter were validated *in vitro* using MR velocimetry. Hemofilters were implanted in large animals (n=4) for 30 days or until thrombosis and then explanted. Based on the CFD results, a subsequent flow path was devised to minimize predicted thrombogenic regions, and simulations were conducted on the second design.

Results: The *in vitro* and *in silico* models showed strong agreement. Pulsatile CFD simulations of the prototype device demonstrated zones of low WSS, and clot formation occurred in two of the four implants at the CFD-predicted sites. Flow simulations of the second-generation design showed reduced areas of low WSS.

Conclusions: Thrombogenic low WSS regions predicted *in silico* correspond with clot formation *in vivo*. In addition to predicting areas of thrombogenicity, CFD can be used to guide hemofilter device design to minimize these sites.

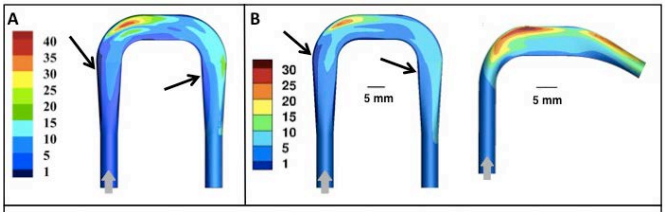

Figure 1. CFD results, with gray arrows indicating flow direction. A) WSS averaged over all but systolic acceleration for the prototype shows low WSS regions (black arrows) dominate the cardiac cycle. B) Compared to the prototype (left), the second-generation (right) design mitigates areas of instantaneous low WSS (black arrows).

FR-PO367

Characterization of Dialyzer Membranes by MALDI-Mass-Spectrometric Imaging Techniques Joachim Jankowski, Vera Jankowski. *Inst of Molecular Cardiovascular Research, Univ Hospital RWTH, Aachen, Germany.*

Background: Dialyzer polymer membranes are grossly classified as cellulose-based and synthetically produced membranes. Although cellulose membrane's clearance and mechanical properties qualify it for use in dialyzer membranes, hydroxyl groups of these membranes lead to strong activation of the complement system. Therefore, recent membranes are manufactured from synthetic polymers.

Methods: For physical and chemical characterization of these materials of dialyzer a wide range of analytical methods is available. Over the last few years, MALDI mass-spectrometry has been developed as a powerful tool for space-resolved analysis, not least because of its mass accuracy and high sensitivity. MALDI imaging techniques combine the potential of mass-spectrometric analysis with imaging as additional spatial information with relevance for biocompatibility of the dialyzer membranes. MALDI imaging enables the visualization of localization and distribution of biomolecules, chemical compounds and other molecules on different surfaces.

Results: In this study, surfaces of polymeric dialyzer membranes, consisting of polysulfone (PS) and polyvinylpyrrolidone (PVP) were investigated, regarding to chemical structure and compound's distribution. According to the manufacturing process luminal and abluminal membrane surfaces are characterized by differences in chemical composition and physical characteristics. The MALDI imaging demonstrated that the abluminal membrane surface is more consisting of polysulfone than polyvinylpyrrolidone, the luminal membrane surface displayed more PVP than PS. The addition of PVP as hydrophilic modifier to polysulfone-based membranes increases the biocompatibility of the dialysis membranes. The analysis of polymer distribution is a relevant feature for characterization of dialysis membranes.

Conclusions: In conclusion, MALDI imaging is a powerful technique for polymer membrane analysis, regarding not only detection and identification of polymers but also localization and distribution in membrane surfaces, which has strong impact on the biocompatibility of the dialyzer membranes.

FR-PO368

Effect of Peristalsis with Pediatric Catheters Anna Lorenzin, Francesco Garzotto, Claudio Ronco. *Nephrology and International Renal Research Inst Vicenza, St. Bortolo Hospital, Vicenza, Italy.*

Background: Thanks to the technological advances of the last years,Continuous Renal Replacement Therapy CRRT machines have been upgraded and equipped with circuits specific for pediatric patients.To date,to treat these patients the most used catheter is the bilumen 7French,however with a neonate it is inadequate for the dimensions.It is not clear if it is possible to use a smaller catheter with adult CRRT machine or a specific pediatric machine is needed.We set up a dedicate circuit to assess the usability of a peristaltic blood pump designed for adults and compare it with a pediatric pump in terms of access pressure.

Methods: We performed in vitro test with milk as medium.The circuit was composed of a bilumen catheter(4Fr-5cm,5Fr-7cm,7Fr-13cm),an arterial pressure sensor,a blood pump and a venous pressure sensore(Fig1).We compared two differet blood pumps:an adult one with10,5cm diameter and a pump line with inner and external diameter of 3.9and7.8mm; a pediatric pump of CARPEDIEM machine with 4cm diamenter and a pump line with inner and external diameter of 3.5and5.5mm.We set the pumps to have flow rates of7,10,15,20ml/min and we recorded the pressure values.

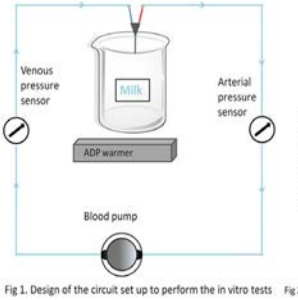

Fig 1. Design of the circuit set up to perform the in vitro tests

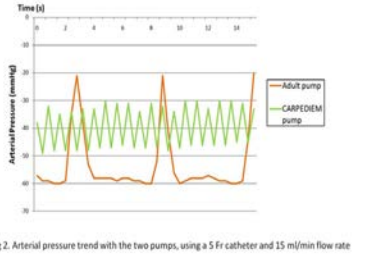

Fig 2. Arterial pressure trend with the two pumps, using a 5 Fr catheter and 15 ml/min flow rate

Results: We are presenting the data of the two pumps with 5Fr catheter and 15ml/min flow rate.Analyzing the arterial pressure values,we found that the spikes are more frequent with the CARPEDIEM pump than with the adult one. The min and max value are respectively(-50,-28mmHg)and a mean Dp=18mmHg with CARPEDIEM pump,(-61;-20mmHg)and a mean Dp=40mmHg with adult pump (Fig2).

Conclusions: We can notice that there is ah high discrepancy in terms of Dp between the two pumps:high values of Dp lead to an high shear stress.As the shear stress in one of the main causes of hemolysis,it seems that a specific pediatric machine is advisable for neonates that need small catheter.Further investigation have to be perform with blood to confirm our results.

FR-PO369

Hemodialysis with CARPEDIEM Machine: An In Vitro Test Anna Lorenzin, Dario Galeano, Stefania Aresu, Francesco Garzotto, Claudio Ronco. *Nephrology and International Renal Research Inst Vicenza, St. Bortolo Hospital, Vicenza, Italy.*

Background: Despite the development of continuous renal replacement therapies machines,their employment still remain unsuitable in new born and infants.This gap has been filled thanks to the coming of a specific pediatric dialysis machine,CARPEDIEM. To date it is set up only for continuous hemofiltration CVVH;to provide a wider range of applications,specific filters have been conceived to implement a continuous hemodialysis CVVHD.We tested a prototype kit to evaluate its performance in terms of clearance K.

Methods: We performed in vitro test with plasma for the 3 filters HD010 HD020 HD035(surface 0.1,0.2,0.35m^2).Fibers were put manually into the housing of CVVH filters.CVVHD in cocurrent configuration(otherwise a longer circuit is required)is carried out using infusion pump as dialysate pump and ultrafiltration as effluent pump.All the combinations of plasma and dialisate flow rate are set(Q_P=5,10,15ml/min,Q_D=5,10,15ml/min),net ultrafiltration is 0ml.Plasma samples are collected every Q_P,Q_D change(time interval 8min)to evaluate K of urea and creatinine using the standard formula.

Results: Among all filters,our tests estimated a common trend of urea K(min 3.0, max 10.5ml/min)and cretinine K(min 3.4, max 11.8ml/min).Filters efficiency increases with the increase of both the flow rates Q_P,Q_D(fig1),moving towards a plateau at the higher flows configuration.

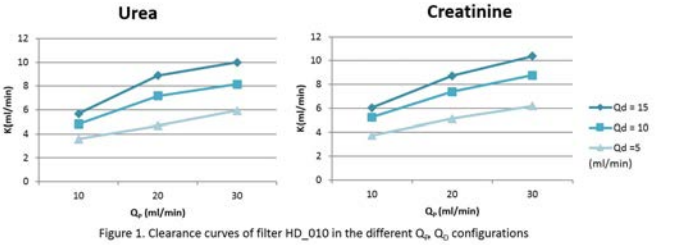

Figure 1. Clearance curves of filter HD_010 in the different Q_P, Q_D configurations

Conclusions: CVVHD with CARPEDIEM seems to be effective for diffusion trasport of small molecular weight solutes,according to specific clinical needs.In the light of these findings CARPEDIEM can be a promising alternative to peritoneal dialysis, i.e. in treating electrolyte imbalance with accurate fluid removal.Limitation:handmade filters could induce variability in the results due to disposition and variable number of fibers.

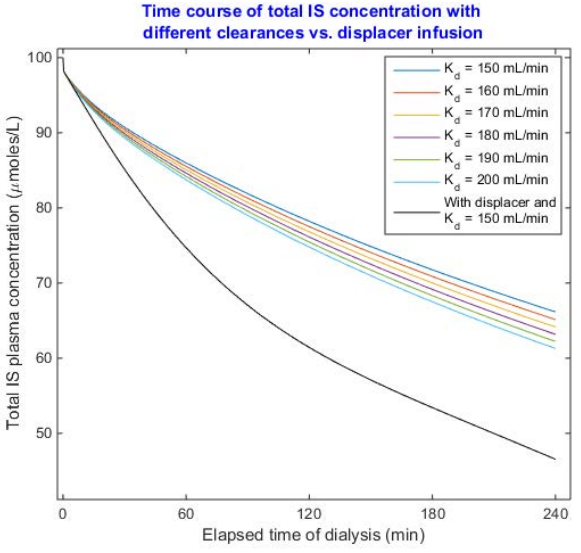
FR-PO370

Removal of Protein-Bound Uremic Toxins: Simulating the Effect of Toxin Displacement versus Increase in Dialyzer Clearance Vaibhav Maheshwari,[1] Stephan Thijssen,[1] Doris H. Fuertinger,[1] Franz Kappel,[2] Peter Kotanko.[1] *[1]Renal Research Inst, NY; [2]Univ of Graz, Austria.*

Background: Protein-bound uremic toxins (PBUT) exert numerous deleterious effects. Their removal with standard hemodialysis (HD) is poor. Meyer *et al*. have modeled the impact of increasing dialysate flow rate and dialyzer mass transfer area coefficient on PBUT removal [JASN, 2004]. Here, we compare those results to a novel approach based on PUBT displacement by infusion of binding competitors [Tao, Blood Purif, 2015].

Methods: We developed a multi-compartment patient model and a dialyzer model depicting spatiotemporal dynamics based on law-of-mass-action kinetics. We chose indoxyl sulfate (IS) as a prototypical PBUT and ibuprofen as the binding competitor. We modeled IS removal during a 4-hr HD (Q_p=250 mL/min, Q_{uf}=750 mL/h, initial total IS 100 µmol/L, initial free fraction of IS 8%), with IS dialyzer clearances from 150 to 200 mL/min. This was compared to IS removal achieved by ibuprofen infusion (800 mg/200 mL) into the arterial line at 50 mL/hr (IS clearance 150 mL/min).

Results: IS removal during HD with a clearance of 150 mL/min was 438 µmoles (plasma reduction ratio 34%), which conforms to literature data [Niwa, Blood Purif, 2012]. With IS clearance of 200 mL/min, removal improved by 8.7% to 476 µmoles. With ibuprofen infusion (IS clearance back at 150 mL/min), removal improved by 11.2% to 487 µmoles.



Conclusions: Our model yields predictions of IS kinetics that agree with empirical and modeled data [Niwa *et al*.; Meyer *et al*.]. Of note, a mere 8.7% improvement in IS removal would require an increase in dialysate flow rate from 800 to 1350 mL/min plus a 70% increase in membrane surface area. The modeled ibuprofen infusion alone yields an 11.7% improvement even absent an increase in dialyzer clearance. The use of binding competitors holds great promise. These results require validation *in vivo*.

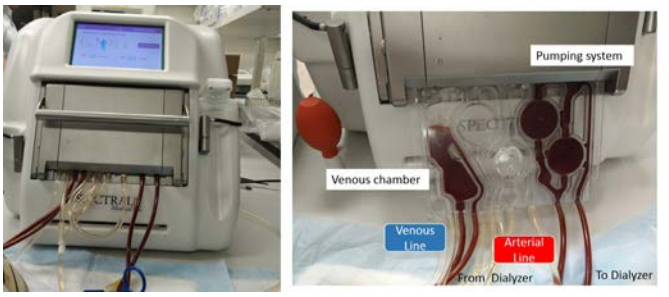
FR-PO371

Membrane Driving Blood Flow for Extracorporeal Therapies Francesco Garzotto, Sean M. Bagshaw, Anna Lorenzin, Mauro Neri, Claudio Ronco. *Nephrology, St. Bortolo H.*

Background: From the first application of ContinuousVenoVenousHemofiltration CVVH, the blood flow has been driven by a peristaltic pump. Several attractive alternatives, with both advantages and disadvantages, have been proposed for many years. SAM (Spectral Medical Inc.; Toronto, Canada) is a novel instrument, in which the pumping of whole blood and fluids is performed through the use of pistons, chambers and valves. A plastic cartridge blood circuit system fig1b incorporates all of the pumps, air trap system, pressure monitors and clamps. This circuit is covered on one side by a plastic membrane adhered to the pumping pistons via a drawn vacuum. Aim of the present is to evaluate the new pumping system.

Methods: We set up the machine for CVVH. An 11.5 Fr 20 cm catheter was connected to the lines. We ran the machine for 6 hours in order to characterize the performance of the system.

During the first cycle, suction generated by the drawing back of the piston, moves the blood into the arterial-chamber AC. Positive pressure generated by the piston then drives the blood through the circuit. The camshaft design can allow different profiles for Withdrawal and infusion flows. The largest Priming volume measured (both the ACs full), is 98 ml with a stroke volume for each AC of 14ml.



Results: We did not observe a reduction of blood flow due to a loss of membrane elasticity. The use of an "all integrated" cassette reduces the number of manual operations, avoiding operator related errors and favoring an easy and time saving set up.

Conclusions: S.A.M could represent a valid alternative to the classic peristaltic pumping system driven machines. Analyzing the pumping-system/cassette equipment, we identified potential advantages, in addition to usability, such as: accurate balancing system, blood flow ideally designed to avoid a membrane protein layer, constant blood flow over time, accurate volumetric balancing system, less clotting activations, and an optimal withdrawal flow profile. More tests should be performed in order to validate the device in various aspects and conditions.

FR-PO372

Membrane versus Peristaltic Blood Pumps for Extracorporeal Therapies: Comparison on Index of Hemolysis Francesco Garzotto,[1] Sean M. Bagshaw,[2] Claudio Ronco.[1] *[1]Nephrology and IRRIV, St. Bortolo H., Italy; [2]Critical Care Medicin, Univ of Alberta Hospital.*

Background: Hemolysis during extracorporeal treatments mainly occurs as a consequence of mechanical stress on the blood. Red blood cell deterioration is undetected because it is far from any acute hemolytic threshold but represents a potential harm for patients. A new membrane-piston driven pump has been recently proposed on the S.A.M.(©Spectral Medical Inc, Toronto) device designed for continuous renal replacement therapies (CRRT). Aim of this investigation is to compare the membrane with peristaltic pumps by measuring the Normalized Index of Hemolysis NIH during in vitro testing.

Methods: Three sessions of hemoperfusion with a line inserted in place of a hemofilter were performed both with SAM and Prismaflex (©Baxter International).A single pool of fresh heparinized bovine blood (Heparin 500 u/L,Hb 12‡1 g/dl,Base Excess 0+/-5 mmol/L) were split into three aliquots containing 900 mL (Control, SAM, Prismaflex) and circulated for 6 hours/session. Bloo±d samples were drawn at baseline, 30 min and every 1 hour. NIH were calculated as median hourly variation of free hemoglobin and used for comparison. Data was compared with two tailed Student's t-test based on F-Test results.

Results: NIH values of 0.12±0.03 and 0.13±0.09 mg/100L for SAM and Prismaflex respectively are lower than those reported in literature due to the simplified circuit used (no vascular access and filter). Creation of hemoglobin between sam and control, and prisma and control are non-significant fig 1a. Slope of the curves that describe the creation of hemolysis are nearly identical with a slow rate of production of free hemoglobin.

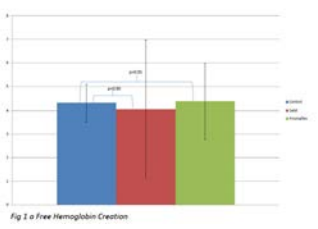


Fig 1 a Free Hemoglobin Creation

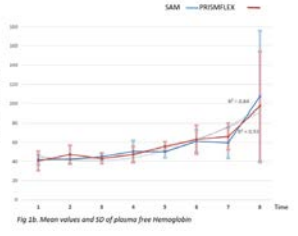

Fig 1b. Mean values and SD of plasma free Hemoglobin

The r^2 close to 1 demonstrate a good linearity of the damage.

Conclusions: Device compatibility in terms of lethal damage to blood cells, is an important aspect of the development of artificial organs. Since a validation based on dangerous level of free hemoglobin do not exist, an empirical evaluation using comparative test suggest that piston driven membrane is safe from a hemolysis point of view.

FR-PO373

Enhanced Middle Molecule Clearance by a Biomimetic Dialyzer Membrane
Joseph J. Groszek,[1] Jin Cheng,[1] Charles Blaha,[2] Rishi Kant,[2] Jaehyun Park,[2] Benjamin Chui,[3] Ken Goldman,[4] Shuvo Roy,[2] William Henry Fissell.[1]
[1]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [2]Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA; [3]Ben Chui Consulting, Sunnyvale, CA; [4]H-Cubed, Inc, Olmstead Falls, OH.

Background: Although polymer dialyzers attain very high small solute clearance rates, polydisperse pore sizes limit middle molecule clearance by conventional polymer dialyzers. We hypothesized that a biomimetic membrane with uniform slit pores would enhance middle molecule clearance.

Methods: thin film silicon membrane samples (surface area 1.4 x 10^{-5} m^2) with monodisperse slit-shaped 5-8 nanometer pores ("SNM-HD") were manufactured as previously described, surface-modified with polyethylene glycol and mounted in a custom designed cartridge. Membrane pore size was estimated from hydraulic permeability measurements. Human blood was spiked with PABA and fluorescent-labelled Ficoll, a polydisperse globular polysaccharide. Blood flow was set at 100 ml/min and dialysate flow varied between 70 and 140 ul/min. Blood and dialysate concentrations of PABA and Ficoll were measured by size-exclusion chromatography. Clearance as a function of dialysate flow rate was extrapolated to estimate KoA as a function of molecular weight.

Results: B2M clearance in high-flux dialyzers is typically 5-8% of the value of urea clearance. PABA clearance was 139 ml/min/m^2. 15.7Angstrom Ficoll (same radius as B2M) clearance in the SNM dialyzers was 16.9 ml/min/m^2, 3-5 fold higher than reported B2M clearance in polymer dialyzers.

Conclusions: A biomimetic membrane of uniform slit pores potentially offers much higher middle molecule clearance than conventional polymer dialyzers.

FR-PO374

Anti-Fouling of Silicon Nanopore Membranes Using SLIPS Bas Meusen,[1,2] Steven Kim,[1] Zohora Iqbal,[1] Charles Blaha,[1] William Henry Fissell,[3,4] Shuvo Roy.[1,3] *[1]UCSF; [2]Univ of Eindoven; [3]Silicon Kidney; [4]Vanderbilt Univ.*

Background: Silicon Nanopore Membranes (SNM) have been developed for application in an implantable bioartificial kidney. However, SNM are subject to fouling and thrombosis with continuous blood exposure. Thin polymer coatings have been applied to SNM as a strategy to limit cell adhesion and protein adsorption. Slippery Liquid Infused Porous Surface (SLIPS) is a bioinspired "omniphobic" surface coating that has been reported to prevent thrombosis and fouling on arteriovenous shunts. Here we present the application of SLIPS coating to SNM and evaluate protein adsorption in vitro.

Methods: SNM with ~10 nm pores were coated with SLIPS and incubated with BSA-FITC (2 mg/ml in PBS) for 24 hours at 37°C. Uncoated (bare) silicon substrates served as controls. Fluorescence microscopy and ellipsometry were used to evaluate the surfaces and water transport through the SNM was tested using established hydraulic permeability assays.

Results: SLIPS strongly reduced BSA-FITC adsorption on SNM compared to bare silicon. Ellipsometry confirmed the presence of SLIPS coating with a thickness of 0.5±0.2nm, which is theoretically thin enough to keep open the pores open in the membrane. However, hydraulic permeability testing revealed no ultrafiltration through the SNM for at least 24 hours and transmembrane pressures of up to 5 psi.

Conclusions: SLIPS is a promising and easy-to-apply protein repellent coating, but its highly omniphobic characteristic prevents ultrafiltration even through pores that are over 5x the coating thickness. For use in the bioartificial kidney, SLIPS has relevant implications as an anti-fouling coating where an ultra-thin blood compatible, but non-filtering surface is desired.

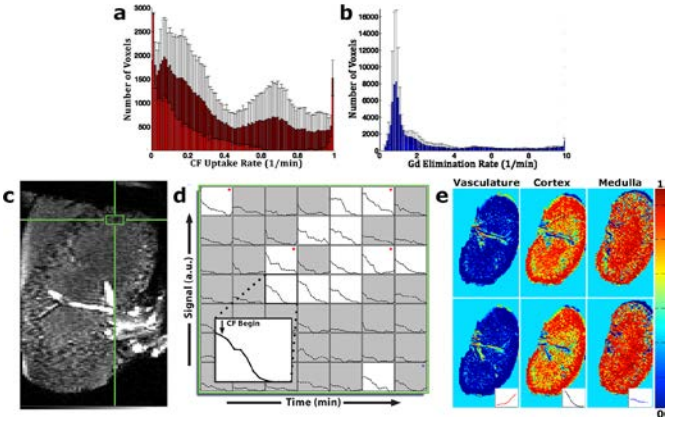
FR-PO375

Measuring Spatial Trends of Single Nephron Filtration with Molecular MRI Edwin Baldelomar,[1] Jennifer R. Charlton,[2] Kevin M. Bennett.[1] *[1]U. of Hawaii, Honolulu, HI; [2]U. of Virginia, Charlottesville, VA; [3]U. of Hawaii at Manoa, Honolulu, HI.*

Background: To better develop drugs to treat kidney disease their physiological mechanisms during development, noninvasive techniques to measure whole kidney function at the level of the single nephron are needed. We investigated the combined use of two MRI contrast agents, cationic ferritin (CF) and Gd-DTPA, to measure local (voxel) macromolecular uptake and glomerular filtration rates of single nephrons over the whole rat kidney with 3D MRI using the isolated, perfused rat kidneys under physiological conditions.

Methods: Krebs-Ringer (KR) bicarbonate solution with 7.5 mg/100mL of Fraction-V BSA and a bubbling infusion of carbogen was perfused into isolated rat kidney. Temp was maintained at 37°C. CF in KR solution (0.071 mg/mL of CF), was infused into the system first. After CF, KR solution was re-infused to wash. Next, a bolus of 0.25 mmol Gd-DTPA in 10mL of KR solution was infused into the perfusion system. (All rates = 5ml/min) Kidneys were imaged during the perfusion with MRI. Voxel time courses were then fitted to a bi-exponential model.

Results: Glomeruli were distinguished by uptake of CF and a distribution of CF accumulation rates and gd-DTPA elimination rates was visible. (Fig 1a-b) We used the location of the glomeruli in 3D and the time course of CF labeling (Fig 1c-d) to discern spatial trends in uptake rate of CF. Time course structures also mapped well with the different morphological structures in the kidney (Fig 1e).



Conclusions: CF and gd-DTPA were used in conjunction to map glomerular filtration in the isolated, perfused rat kidney in 3D. To our knowledge this is the first report to assess spatial trends with macromolecular and free filtration dynamics in the whole kidney.

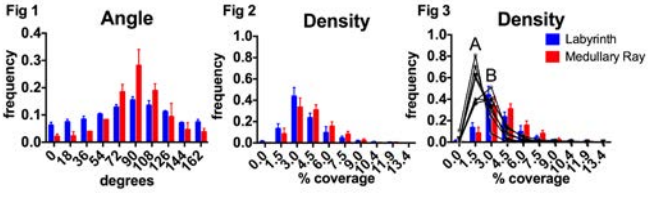
Automated Quantification of Renal Microvascular Abnormalities: A Novel Computational Mapping Approach Kyle I. Harrington, Beverly Elizabeth Faulkner-Jones, Katie Bentley, Seymour Rosen. *Pathology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Alteration of the microvasculature is considered to be crucial to the understanding of chronic kidney disease, yet few studies have quantified the microvasculature in normal and diseased kidneys.

Methods: We created customized software for automatically quantifying morphology of renal microvasculature. 10 kidneys (2 nephrectomies, 8 biopsies) were studied; 3 cases of relatively normal tissue, others chosen because of a significant degree of tubulointerstitial injury and included a variety of diseases (diabetes, amyloidosis, end-stage glomerulonephritis, and renal artery stenosis). Images of CD34 stains were segmented, high-pass filtered based on size, and glomeruli were manually segmented. Morphological signatures were calculated using 3 parameters: roundness, angulation, and density.

Results: The normal cortex, as a whole, presented heterogeneity in histogram analysis. However, color density mapping and histogram studies revealed 3 distinct regions: glomeruli (GM), labyrinth (LB), and medullary ray (MR). MR was characterized by correlated angulation (Fig 1). Microvascular density varied in LB but peaked at 3% coverage within a 200um circular radius (Fig 2). Density in MR was approximately the same. As expected, GM density was far greater, sometimes exceeding 11% coverage. With disease, capillary shape did not shift, roundness factor remaining in 0.2-0.3 range (circular profile 1.0). However, diminishment in capillary density was overt (Fig 3), and distribution shifts were marked (peak A) or more moderate (peak B).



Conclusions: Our results demonstrate that automated quantification is capable of not only distinguishing between anatomical features of kidneys, but also characterizing the degree of abnormality in diseased tissue.

FR-PO377

Angio-μCT: New Polymer-Based Contrast Agent Makes Kidney Morphometry Look Attractive Ruslan Hlushchuk, Sebastien Barre, Carlos Correa Shokiche, Valentin Djonov. *Inst of Anatomy, Univ of Bern, Bern, Switzerland.*

Background: The fundamental features of the morphological substrate of the renal function are nephron number and glomerular volume. The accurate estimation of these parameters has become increasingly important. The present ***golden-standard*** method of kidney morphometry is the exhaustive physical fractionator/dissector method. It is extremely time-consuming and laborious, let alone disturbing proceeding artefacts. **Purpose:** to develop a contrast agent appropriate for high-resolution μCT *ex vivo* with superior perfusion features in order to visualize the vasculature and glomeruli of rodent kidney. The elucidated approach should allow ***fast and reliable*** estimation of such parameters as nephron number, glomerular volume, glomerular size distribution and kidney volume.

Results: the developed contrast agent (μAngiofil) turned out appropriate for μCT *ex vivo* with superior perfusion and contrast-to-noise features. The obtained μCT datasets were of superior quality and allowed clear visualization of the microvasculature and glomeruli.

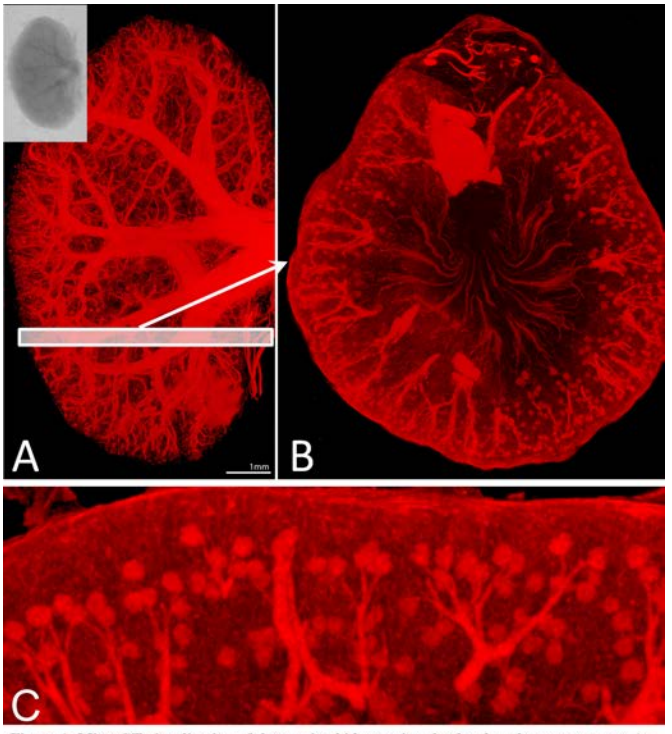


Figure 1: MicroCT visualization of the murine kidney using the developed contrast agent. A - Overview of the vascular network. B - virtual cut of the obtained 3D volume. C - visualization of the glomeruli (sphere-like structures)

In kidney, modern high-resolution microCT (SkyScan-1172) provided the whole mouse *kidney* vasculature in 3D with the spatial resolution of approx. 2 μm. The sample is fixed prior the microCT-scan and therefore can be processed for the histological evaluation after the scan. This circumstance brings multiple advantages, including much easier localization of the μCT-findings in the post-scan histological sections.

Conclusions: using μAngiofil we obtained 3D-μCT datasets of superior quality, which are sufficient for estimation of relevant kidney morphometry parameters. ***The developed angio-μCT-based approach will substitute the existing golden-standard.*** *Besides* classical kidney morphometry, it provides the data on the vasculature through the whole kidney in 3D what makes the technique even more beneficial.

FR-PO378

Rising Accuracy of Transcutaneous GFR Measurement Jochen Friedemann,[1,2] Ralf Heinrich,[3] Yury Shulhevich,[1,2] Johannes Pill,[2] Daniel Schock-Kusch.[1,2]
[1]Mannheim Univ of Applied Sciences, Inst for Process Control and Innovative Energy Conversion, Germany; [2]Mannheim Pharma & Diagnostics GmbH, Germany; [3]Freudenberg New Technologies SE & Co. KG, Weinheim, Germany.

Background: Transcutaneous measurement of GFR ($_t$GFR) is now getting used frequently in animal studies. tGFR allows consecutive GFR measurements in the same animal even on a daily basis as no blood sampling is required. Here we describe and validate a novel three compartment model ($_t$GFR$_{new}$) for $_t$GFR assessment by FITC-Sinistrin clearance, automatically correcting influences like bleaching of skin fluorescence.

Methods: Bolus clearance $_t$GFR was measured in awake Spraque Dawley (SD) rats using the commercially available NIC-Kidney system, immediately followed by a blood sampling based constant infusion clearance (cGFR). GFR was calculated by a one compartment model ($_t$GFR$_{std}$), $_t$GFR$_{new}$ and cGFR. Also 46 $_t$GFR measurements in SD rats were reevaluated by $_t$GFR$_{new}$.

Results: Results are given in table 1. Mean values of the three methods are comparable with no significant difference. The accuracy (larger STD) of $_t$GFR$_{std}$ is lower compared to $_t$GFR$_{new}$ and cGFR. This finding was verified by the 46 measurements in SD rats ($_t$GFR$_{std}$: 0.97 ± 0.18 ml/min/100g b.w.; $_t$GFR$_{new}$ 0.95 ± 0.14 ml ml/min/100g b.w.).

n=11 SD rats	cGFR	$_t$GFR$_{std}$	$_t$GFR$_{new}$
	ml/min/100g b.w.		
mean ± STD	0.94 ± 0.13	1.00 ± 0.18	0.88 ±0.12
effect size$_{10\%}$	0.73	0.55	0.73

Conclusions: The results indicate that tGFR-$_{new}$ yields data in comparable accuracy as cGFR. For an apriori estimation of the sample size to detect a change in GFR of 10% in the SD rats investigated, the effect size rises from 0.55 ($_t$GFR$_{std}$) to 0.73 (tGFR$_{new}$). The required sample sizes in fig. 1. illustrate the strong contribution of $_t$GFR$_{new}$ to the concepts of refining and reduction of animal studies.

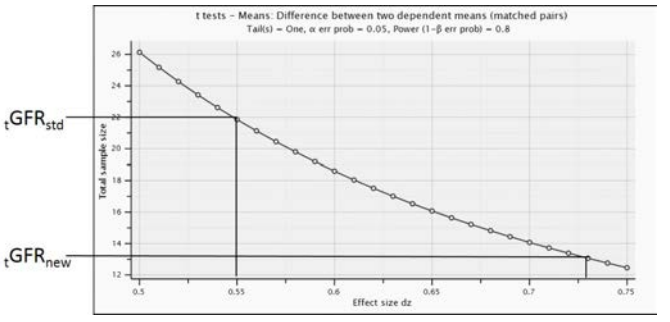

Figure 1: Impact of the increased effect size yield with $_t$GFR$_{new}$ compared to $_t$GFR$_{std}$.

FR-PO379

Quantification of the Progressive Fibrosis Development in Mouse Kidney Unilateral Ureteral Obstruction Model Using Fluorescence Lifetime and Second Harmonic Generation Imaging Microscopy Evgenia Dobrinskikh,[1] Suman Ranjit,[2] John Ross Montford,[1] Alexander Dvornikov,[2] David J. Orlicky,[1] Allison M.b. Lehman,[1] Raphael A. Nemenoff,[1] Enrico Gratton,[2] Seth B. Furgeson,[1] Moshe Levi.[1] *[1]Univ of Colorado Denver; [2]Univ of California Irvine.*

Background: Renal fibrosis is considered to be the final common pathway for most forms of chronic kidney disease (CKD) and involves glomerular sclerosis and/or tubulointerstitial fibrosis. There is great interest in identifying renal fibrosis in the early stages of CKD to prevent progression. Unilateral ureteral fibrosis (UUO) is a well-characterized model of CKD and renal fibrosis. Kidney injury and fibrosis usually are assessed by Picrosirius Red staining or immunohistochemistry for collagen isoforms.

Methods: The goal of this study is to compare histologic measures of renal fibrosis to Fluorescence Lifetime Imaging (FLIM) and Second Harmonic Generation (SHG) techniques in our deep imaging microscope DIVER.FLIM and SHG allow quantification of collagen in unstained tissue and can be adapted for live animal imaging. Male C57BL/6 mice were subjected to UUO of right kidney. At 7, 14 and 21 days, both kidneys were harvested. The uninjured left kidney was used as a control. Serial sections of both kidneys were analyzed by Picrosirius Red staining or FLIM with SHG.

Results: We performed quantification of Picrosirius Red stained-kidneys using polarized light. This showed progressive increase for the number of positive pixels for fibrosis in the left kidney 9631.9±0.1626.2, 16167.8±6647.7 and 20511.5±5727.6 compared to 5625.3±770.6, 3909.33±2395.9 and 4493.8±2018.4 in the control kidney respectively. Using the Phasor approach to FLIM, comparisons between the two kidneys show that the auto fluorescence lifetime signature give rise to two well separate phasor clusters. Quantification of ten different fields of view for each kidney at the above time-points for SHG signal confirms Picro-Sirius Red scoring.

Conclusions: Finally, the combined FLIM and SHG images let us establish a criterion for quantitative determination of fibrosis directly from the microscope images.

Chemical Imaging: A Novel Approach to Obtaining Label-Free Biochemical Information in Renal Transplant Patients with Recurrent Diabetic Nephropathy Michael J. Walsh,[1] Vishal K. Varma,[1] Andre Kajdacsy-Balla,[1] Sanjeev Akkina,[2] Suman Setty.[1] *[1]Dept of Pathology, Univ of Illinois at Chicago, Chicago, IL; [2]Dept of Nephrology, Univ of Illinois at Chicago, Chicago, IL.*

Background: The main treatment for end-stage renal disease is kidney transplantation, which over time undergo chronic rejection including changes in the glomerular, tubulointerstitial and vascular compartments. Also, recurrence of disease in diabetics can mimic transplant glomerulopathy. We have identified biochemical markers using Chemical imaging that were associated with recurrent diabetic nephropathy. Chemical Imaging is an emerging approach to obtain images of the biochemical composition of tissue biopsies in a label-free fashion.

Methods: An initial study focused on identifying patients with no evidence of diabetic nephropathy and patients with advanced diabetic nephropathy in native kidneys. Serial sections were acquired and stained with PAS or imaged using chemical imaging. IR spectra were extracted to identify biomarkers associated with diabetic nephropathy progression. A second study identified transplant patients who underwent very rapid recurrent diabetic nephropathy and patients with no evidence of diabetic nephropathy.

Results: Biomarkers were identified that were changed in renal structures associated with the progression of diabetic nephropathy, including increased levels of glycation. These biomarkers were found to be increased in the cohort of transplant patients that underwent rapid diabetic nephropathy recurrence. In addition, the early biopsies from the patients that underwent later diabetic nephropathy progression were biochemically different from the non-progressive patients, suggesting that chemical imaging may identify pre-histological biomarkers that will predict outcome.

Conclusions: We have identified a number of biomarkers that are associated with the advancement of diabetic nephropathy and that we can track the early recurrence of diabetic nephropathy in surveillance biopsies. In addition, we have highlight a 'biochemical-signature' that may be predictive of the later progression of diabetic nephropathy recurrence.

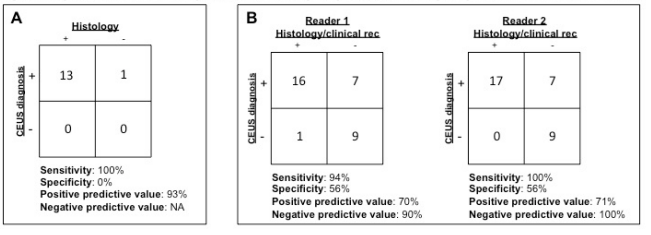
Contrast-Enhanced Ultrasound Characterizes Kidney Lesions with Accuracy Comparable to Contrast-Enhanced CT or MR Emily H. Chang,[1] Sandeep Kasoji,[1,2] Paul Dayton,[1,2] Wui K. Chong,[1] Kimryn Rathmell.[1] *[1]Univ of North Carolina, Chapel Hill, NC; [2]North Carolina State Univ, Raleigh, NC.*

Background: Incidental kidney lesions are often detected on imaging performed for other reasons. Indeterminate lesions are further characterized with a contrast-enhanced computed tomography(CT) or magnetic resonance imaging(MRI). These tests have many limitations and are contraindicated in patients with allergies to contrast, metallic hardware and chronic kidney disease(CKD). An accurate alternative study is needed. Contrast-enhanced ultrasound (CEUS) is one potential alternative. CEUS uses microbubbles, non-nephrotoxic, gas filled bubbles with lipid or albumin shells, as the contrast agent. We investigated the accuracy of CEUS for malignancy in patients with incidental kidney lesions.

Methods: CEUS was performed on 33 patients. Results were independently interpreted by 2 blinded readers and risk-stratified by the Bosniak classification system. Sensitivity, specificity and predictive values were calculated for lesions with histologic diagnosis as the gold standard. As histology was available for resected lesions only, we performed secondary analyses using an expanded gold standard definition that included clinical recommendation.

Results: Of the 33 patients, 12 had CKD and 14 had histologic diagnoses. There was 100% inter-reader agreement in the primary analysis (Figure 1A) and 97% agreement in the secondary analysis (Figure 1B). Sensitivities (94-100%), positive (70-93%) and negative predictive (90-100%) values for CEUS were comparable to CT (83-100, 50-67 and 77-100%, respectively) and MRI (81-100, 60-78 and 80-96%, respectively). CEUS specificity (0-56%) was lower than MRI (71-100%).

Figure 1. Diagnostic accuracies based on gold standard of histologic diagnosis (A) and histologic diagnosis or clinical recommendation (B).



Conclusions: CEUS has excellent potential as an alternative diagnostic tool for kidney lesions among patients with CT/MRI contraindications. Further evaluation is needed.

FR-PO382

Lead-Free Drape Applied to Xray Detector Significantly Decreased Radiation Scatter During Access Intervention Jie Cui,[1] Fengyong Liu,[2] Zubin Irani.[3] *[1]Nephrology Dept, Massachusetts General Hospital, Boston, MA, China; [2]Interventional Radiology Dept, Chinese People's Liberation Army General Hospital, Beijing, China; [3]Div of Vascular Imaging and Intervention, Massachusetts General Hospital, Boston, MA, China.*

Background: Exposure from scattered radiation can be very high during access interventional procedures because of the relatively closer operative position. The purpose of this study is to evaluate whether applying a lead-free, sterile, disposable drape can decrease scatter radiation exposure during access intervention.

Methods: An upper extremity phantom was placed on the angiography table to mimic real-time patient's upper extremity access. Using this model, measurement of scatter radiation was made every one foot away from the phantom before and after applying the drape using a collimated and low-output condition. The scattered radiation dose was measured three times in each spot. And the measurement was taken at 0.9m (waist level) as well as neck level (1.5m). Statistical significance was compared using t-test.

Results: Scatter radiation was attenuated throughout the measurement field when the drape was applied. The degree of scatter radiation reduction was distance and height dependent. Scatter radiation decreased 61.6% at the waist level and 81% at the neck level ($P<0.05$).

Conclusions: The application of this sterile, lead-free drape can significantly reduce scatter radiation in the procedure room. This novel technique can be used to reduce exposure radiation dose to the operators.

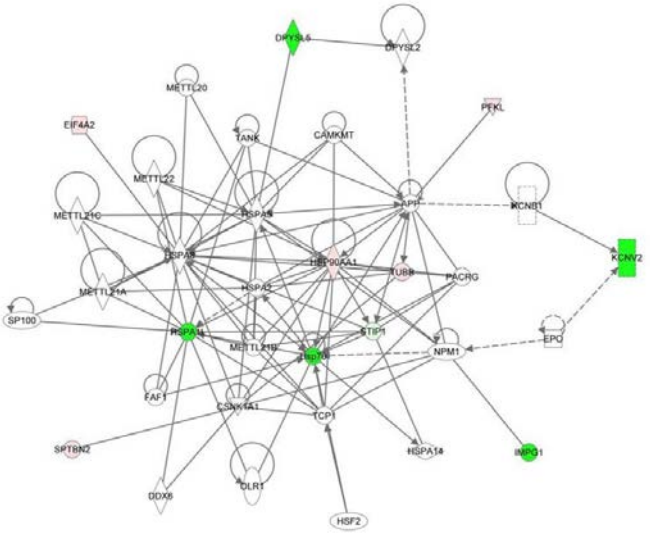
FR-PO383

Pathogenesis of Brain Damages in Chronic Kidney Disease and Clues for Early Diagnosis Yao-ping Lin,[1,2] Der-Cherng Tarng.[1,2] *[1]Medicine, National Yang-Ming Univ, Taipei, Taiwan; [2]Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: There is globally increased prevalence of chronic kidney disease (CKD). Vigorous efforts have been devoted to ameliorate renal deterioration and prevent cardiovascular morbidity/mortality. However, patients also have enough incubation time to develop deranged cognition that severely disturbs quality of life. Neurological pathology/damages may occur in CKD patients long before any overt clinical symptoms can be noticed. Given the similar embryological development as brain, the eyes can be the windows to pinpoint the internal brain pathology. Herein we employed proteomics, animal model and behavior analysis to investigate the possible overlapping biological signatures in the eyes and brain of CKD.

Methods: Subtotal nephrectomized rats were established as CKD model. Open field and object recognition tests were adopted as neurologiocal screen. Brain and eyes were harvested for proteomic analysis. Western blotting and immunohistochemistry were used to confirm and localize the identified proteins. To elucidate the global protein changes in the brain and eye of SNX rats, the data was analyzed by Ingenuity Pathways Analysis (Ingenuitys Systems, http://www.ingenuity.com/).

Results: The eye pathology appeared in parallel with the brain damages. The significaly dysregulated proteins in the SNX rat eyes were spectrin beta 3, 26S proteasome non-ATPase regulatory subunit 2,6-phosphofructokinase, dihydropyrimidinase-related protein, and the heat shock 70, 90α, and chaperonin containing Tcp1, subunit 6A (Zeta 1).



All these proteins have been linked to the neuro-degeneration in humans.

Conclusions: There were overlapping eye and brain biological networks. Our results might pave the way for early diagnosis of CKD-neurological pathology via eye examinations, and targeted interventions towards the neurological diseases.

FR-PO384

Metabolomic Profiling of Chronic Kidney Disease Using a Local Exhaustive Exploration Approach Margaux Luck,[2] Eric Thervet,[1] Cécilia Damon,[2] Nicolas Pallet.[1] *[1]Nephrology, Georges Pompidou European Hospital, Paris, France; [2]Hypercube Inst, Paris, France.*

Background: ^{1}H Nuclear Magnetic Resonance (NMR)-based metabolic profiling is useful for the diagnosis of CKD stages. Due to the high dimension of NMR spectra datasets and the complex mixture of metabolites in biological samples, the identification of discriminant biomarkers of a disease is challenging. None of the widely used chemometric methods in NMR metabolomics performs local exhaustive exploration of the data.

Methods: We developed a descriptive and easily understandable approach searching for discriminant local phenomena. We selected the most discriminant features from the dataset based on both the normalized mutual information and the chi-2 test. We studied the local distribution of the patient subgroups with identical degree of CKD severity on each feature, using the proprietary algorithm HyperCube, which searches for local overdensities of an explanatory variable modality, and identifies a combination of variables as well as their value ranges that give the optimal prediction of the outcome of interest. Further, logistic regression on these discriminant features was used to build a predictive model of the CKD severity stage.

Results: We explored a complex dataset that includes ^{1}H-NMR urinary metabolomics, clinical, demographic, clinical chemistry and histo-pathological variables, in a cohort of 110 individuals with a CKD. The HyperCube algorithm combined with logistic regression supports the discriminant metabolites obtained with standard Orthogonal Projection to Latent Structure Discriminant Analysis (O-PLS-DA) model. Unlike the O-PLS-DA model, HyperCube algorithm provided clues into the distribution of the CKD severity subgroups

with respect to spectral data. The built predictive model identifies metabolomics profiles composed of metabolites such as citrate, dimethylsulfone, trigonelline and glycine. The majority of the predictive variables were urinary metabolites identified by ^{1}H-NMR, indicating that CKD significantly impacts the urinary metabolome.

Conclusions: Our findings indicate that HyperCube is a valuable analytical method for the description of CKD severity phenotypes.

FR-PO385

RNA-seq Profiling in Uninephrectomized Rats Jae Wook Lee, Mark A. Knepper. *NHLBI, NIH, Bethesda, MD.*

Background: Renal hypertrophy occurs as a compensatory response to reduction in nephron mass. To identify early gene expression changes in renal hypertrophy, we profiled whole-kidney transcriptome in the contralateral kidney of uninephrectomized rats using RNA-seq.

Methods: 5-week-old male Sprague-Dawley rats received right uninephrectomy (UNx, n=4 at each time point) or sham surgery (S, n=4 at each time point). Rats were sacrificed at 24, 48, and 72 hours after surgery. 1.5 µg of total RNAs from the left kidney was used to make cDNA libraries for Illumina sequencing. Reads were mapped to Ensembl genes and Wald test for a negative binomial model was used to call differentially expressed genes.

Results: Total RNA yields did not differ significantly between UNx and sham kidneys. Each library had 35-42 million reads and more than 80% of reads were uniquely aligned. At 24 h, 45 transcripts were upregulated and 72 downregulated in UNx. Upregulated transcripts included connective tissue growth factor (*Ctgf*), regulator of cell cycle (*Rgcc*), serum/glucocorticoid-regulated kinase (*Sgk1*), glucocorticoid-induced leucine zipper protein (*Tsc22d3*), a zinc finger transcription factor (*Zbtb16*), and genes related to steroid biosynthesis (e.g. *Insig1*). At 48 h, 183 transcripts were upregulated and 103 downregulated in UNx. Among upregulated transcripts were cell-cycle genes including centromere proteins (*Cenpa*, *Cenpf*, and *Cenpi*); MMC helicase subunits (*Mcm3*, *Mcm5*, and *Mcm8*); cyclins (*Ccna*, *Ccnd1*, *Ccne*, and *Ccnf*); cyclin-dependent kinase (*Cdk1*); and polo-like kinase (*Plk1*). Among downregulated transcripts at 48 h were transcription factors (*Jun*, *Hmx2*, *Klf9*, *Klf15*, *Foxo3*, *Zfp36*, *Zfp354a*, *Zbtb16*, and *Zhx3*). At 72 h, 769 transcripts were upregulated and 704 downregulated in UNx. Upregulated transcripts included *Ctgf*, *Sgk1*, *Zbtb16*, and cyclins (*Ccnb1*, *Ccna2*, *Ccnb1*). Interestingly, *Ctgf*, *Sgk1*, *Zbtb16*, and *Tsc22d3* showed a triphasic response, upregulated at 24 h and 72 h and downregulated at 48 h, consistent with an underdamped control system.

Conclusions: RNA-seq revealed upregulation of multiple transcripts involved in cell division as a central mechanism of compensatory response in the contralateral kidney after uninephrectomy. Genes upregulated at 24 h such as *Ctgf*, *Rgcc*, *Sgk1*,and *Tsc22d3* may trigger this response.

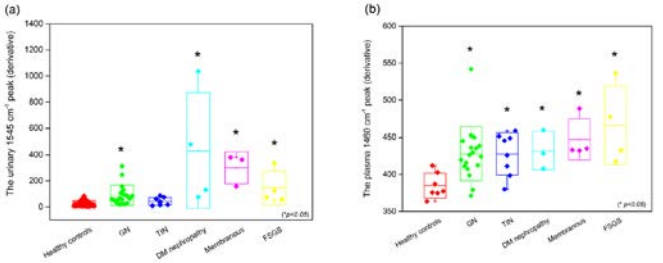
FR-PO386

The Application of Potential Label-Free Mid-Infrared Biomarkers in Patients with Biopsy-Proven Kidney Diseases Mei-Ching Yu,[1,2] Peter R. Rich,[3] Vinod Sathyanarayana Dibbur,[2] Jennifer Smith,[2] Robert J. Unwin,[4] Frederick W.K. Tam.[2] *[1]Paediatric Nephrology, LinKou Chang Gung Medical Centre, Taiwan; [2]Imperial College Kidney & Transplant Centre, Hammersmith Hospital, United Kingdom; [3]Structural and Molecular Biology, Univ College London; [4]UCL Centre for Nephrology, Univ College London, Royal Free Hospital.*

Background: We have previously discovered novel spectral markers, the urinary 1545 cm^{-1} & plasma 1460 cm^{-1} peaks,indicating progression of experimental GN using Fourier transform infrared spectroscopy (FTIR) (2013 & 2014 ASN). In this study, the aims were to investigate these spectral markers in patients with different biopsy-proved kidney diseases, and the correlations between the spectral markers with clinical features.

Methods: The urine and plasma samples were collected at the time of renal biopsy from 50 patients at Imperial College Renal & Transplant Centre, London, UK and compared with healthy volunteers. All samples were measured by FTIR spectrometer and analysed by the established method. The biochemistry results such as urine protein/creatinine ratio (uPCR), Scr and renal histopathology were collected.

Results: In comparison with healthy volunteers, patients with GN, diabetic nephropathy (DN), membranous nephropathy and FSGS exhibited significantly higher levels of the urine 1545 cm^{-1} marker. Furthermore, this urine spectral marker correlated with uPCR in both GN and DN ($p<0.05$).There was significant elevation of the plasma 1460 cm^{-1} marker in all the disease groups compared with healthy volunteers.



Interestingly, for DN, this plasma spectral marker correlated positively with the degree of interstitial fibrosis, tubular atrophy and Scr ($p<0.05$).

Conclusions: Our results show the use of the specific urine and plasma FTIR biomarkers will be a novel approach to investigate progressive kidney diseases, including GN and DN, without chemical manipulation of samples.

Omics Investigation of Urine Samples with and without Addition of a Protease Inhibitor Claire Boulange,[1] Ilse M. Rood,[2] Petra Zürbig,[3] Manuja Kaluarachchi,[1] Elaine Holmes,[1,4] Franz S. Schaefer,[5] John C. Lindon,[1,4] Jack F. Wetzels,[2] Jeroen Deegens.[2] *[1]Metabometrix Ltd, London, United Kingdom; [2]Dep of Nephrology, RadboudUMC, Nijmegen, Netherlands; [3]Mosaiques Diagnostics GmbH, Hannover, Germany; [4]CSM, Dep of Surgery & Cancer, Imperial College London, London, United Kingdom; [5]Dep of Nephrology, Univ of Heidelberg, Heidelberg, Germany.*

Background: Urine is an ideal biofluid for biomarker discovery. To conserve the protein profile integrity, samples are stored with a protease inhibitor (PI). It is unknown whether the PI alters the metabolomic and proteome profiles. This study aimed to test the influence of the PI on metabolomic and proteomic analysis of urine samples.

Methods: We collected 10 urines from normal controls (NC; n=4) and membranous nephropathy patients (MN; n=6) and the samples were aliquoted. A PI (mini complete, Roche) was added to an aliquot of each sample. Urine samples were stored at -80°C. For metabolomics, samples were analyzed by ^{1}H NMR spectroscopy and HILIC-UPLC-MS. Multivariate analysis (MVA) was used to elucidate any PI effect in normal urine and proteinuria. For peptidomics, capillary electrophoresis-coupled mass spectrometry was used to profile the low molecular weight proteome in urine.

Results: Unsupervised MVA of urine NMR metabolic profiles showed clear discrimination between NC-PI, NC+PI, MN-PI and MN+PI. Supervised MVA of PI+ and PI- samples revealed subtle changes in metabolite levels and the presence of intense signals between 3.63 to 3.91 ppm in the PI+ samples, obscuring endogenous metabolite peaks. Unsupervised MVA of HILIC-UPLC-MS data showed discrimination between MN-PI and NC-PI. Supervised MVA of PI+ and PI- samples showed no detectable difference between these two sample types. For peptidomics, MVA between PI+ and PI- resulted in no statistically significant peptide differences. Further validation with a proteome classifier for CKD (CKD273) showed no statistical significant difference between samples with and without PI.

Conclusions: The PI addition did not affect the distinction between MN and NC in the metabolome and proteome analysis. However, PI may affect the analysis of metabolic subclasses using NMR. Therefore, samples with PI can be used, but with caution.

Funding: Other NIH Support - The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7/2007-2013) under grant agreement no. 305608 (EURenOmics).

CNVkit – Software Tools for Analyzing Genomic Structural Variants David Fasel, Miguel Verbitsky, Simone Sanna-Cherchi. *Medicine, Columbia Univ Medical Center, New York, NY.*

Background: Copy number variations (CNVs) are increasingly recognized as genetic susceptibility factors for kidney disease. Determining whether CNVs are pathogenic or associated with a specific phenotype is challenging and few tools exist to aid in this process. Here we describe new software tools that provide semiautomated and flexible annotation and case-control analyses.

Methods: Copy number variations can be detected by multiple technologies, including DNA microarrays and next-generation sequencing (NGS). They span a few hundred base pairs to several million, often disrupting multiple genes. Our first software tool allows for customizable annotation of CNVs, and is flexible to keep up with changing annotation databases. The second tool compares the genomic coordinates of CNVs in case and control populations, and finds matching CNVs based on the percentage of mutual overlap. The tool then performs a Fisher's Exact tests on each pair of matching CNVs. The tool can also be used to compare CNVs with known pathogenic or benign variants. The software runs using command-line inputs and is able to handle data from tens of thousands of individuals in a timely fashion.

Results: CNVkit was recently used as a key component of a study (Verbitsky, JCI 2015), which compared CNVs in 419 children with chronic kidney disease against those found in 21,575 controls, and against predefined coordinates of known genomic imbalances. The software was used to homogenize results and output from different detection platforms, including array CGH, DNA SNP microarrays, and NGS, and to perform joint analyses. It was also used to identify copy number variable regions by using a sliding window approach to detect regions or genes that are enriched for deletions or duplications.

Conclusions: Structural variants are major susceptibility factors to congenital kidney malformations and pediatric kidney disease, and should be considered when investigating the cause of genetic disorders. CNVkit provides freely available and easy-to-use tools to help CNV annotation and interpretation.

Quantifying Uropathogenic Bacteria Infection in 3D Neal A. Paragas,[1] Alexander Klose.[2] *[1]Medicine, Univ of Washington, Seattle, WA; [2]In Vivo Analytics, Inc, New York, NY.*

Background: Urogenital tract infection is a disease that annually afflicts more than 250 million people worldwide; however, the number of antibiotic resistant strains have been increasing while newly validated antibiotics have been lagging behind. We have developed a method to monitor and quantify a uropathogenic bacterial infection with the multispectral bioluminescence tomography (BLT) of a novel bioluminescent uropathogenic E. coli (UPEC-lux).

Methods: We modeled pyelonephritis by transurethral injection of UPEC-lux. First, we acquired bioluminescence images with a bioluminescent optical imager at four different spectral windows centered at 575, 615, 655, 695 nm and with bandwidth of 50 nm. The multi-orientation images were acquired using a mirror gantry for simultaneous imaging of the dorsal and ventral view. The animal was placed in a fixed position into a novel body shape conforming animal mold, placed onto the mirror gantry and spectral images were acquired. For in vivo bacterial quantification, a novel calibration device using tissue mimetic material was used.The light intensity imaging data became input to a novel BLT reconstruction algorithm based on an expectation-maximization (EM) method and the simplified spherical harmonics (SP3) equations for modeling in vivo light propagation. Post reconstruction, we calculated the total photon emission density of a volume of interest (VOI).We then calculated the in vivo organ bacterial load by co-registering it to a novel organ probability map.

Results: The EM method reconstructed the 3D photon emission density of the UPEC-lux and mapped the signal to a novel organ probability map. We analyzed these UPEC-lux in a model of pyelonephritis and we were able to determine the bacterial load in the kidney by BLT which correlated to CFUs from serial dilution of kidney homogenate (Pearson correlation coefficient R2=0.92). For the first time, we could demonstrate the feasibility of determining the bacterial burden in the kidneys.

Conclusions: The ability to monitor bioluminescent signal non-invasively will be a powerful tool to understand the pathophysiology of urinary tract infections and a new method to test novel antibiotics.

FR-PO390

Public Engagement of Kidney Related Health Information on the Internet Samir Sulaiman, Joseph A. Vassalotti, Vijay Lapsia. *Medicine, Icahn School of Medicine, New York, NY.*

Background: The National Kidney Disease Education Program (NKDEP), a part of the National Institutes of Health (NIH) provides an authoritative, up-to-date and trusted consumer health information resource for patients with kidney disease. We hypothesized that the US government (GOV) supported websites would have the highest consumer engagement of kidney related health information on the internet.

Methods: We used traffic rank based on publicly available data obtained from alexa.com and semrush.com, as a marker of website consumer engagement and popularity. We identified the top websites in the health category and disease sub-categories. The websites were classified based on ownership and data collected on unique US visitors, rank, page views per visitor and daily time spent.

Results: In the general health category, the NIH website ranked at the top; however, the consumer focused NLM website ranked 9th, behind webmed.com (2nd) and mayoclinic.org (5th). Among the top 25 websites across all disease categories, Davita.org, a for-profit business, was the only kidney related website. Cancer was the only disease condition with more than 1 website in the top 25 (7 total). The NKDEP ranked 8th in the genitourinary disorders group. The NKDEP had fewer unique US visitors (59,408) compared to Davita.com (307,729) and Kidney.org (241,550).

Rank	Website	Unique US Visitors *	Global Rank	US Rank	Daily Pageviews per Visitor	Daily Time
1	Davita.com	307,729	41,440	8,699	3.98	5:36
2	Kidney.org	241,550	59,136	17,450	1.94	3:02
3	Depend.com	107,230	199,782	40,617	2.5	3:16
4	Kidneyfund.org	81,945	197,479	53,036	1.73	3:02
5	Auanet.org	37,892	229,408	68,797	2.2	2:34
6	ic-network.com	44,773	270,113	58,424	2.5	3:45
7	Urologyhealth.org	68,523	184,328	86,788	1.24	2:06
8	Nkdep.nih.gov	59,408	subdomain data NA			
9	Renalinfo.com	NA	738,600	401,828	2.1	1:55
10	Kidneyurology.org	NA	929,030	415,571	1	1:43

***Estimates as of 05/15/2015**
NA: Not available

Conclusions: In terms of consumer engagement, the kidney specific NIH website - NKDEP, as well as the non-profit kidney.org supported by the National Kidney Foundation were out performed by Davita.com, a publicly listed for-profit company by an unexpectedly wide margin.

FR-PO391

Media Awareness and Reporting of Dialysis Disruptions and Death from Natural Disasters in the United States Samir Sulaiman, Lindsay E. Jubelt, Vijay Lapsia. *Medicine, Icahn School of Medicine, New York, NY.*

Background: Patients receiving in-center hemodialysis are particularly vulnerable during and after disasters. Evidence of morbidity/mortality from disruption to dialysis in a disaster is limited and is so far based on statistical inference. We investigated media awareness and reporting of dialysis disruptions and death during natural disasters in the US.

Methods: We identified all major disaster declarations by the US Federal Emergency Management Agency. Disasters since 2000, excluding man-made and wildfires, with at least 1 known death were included. We then conducted a systematic Google News search to identify articles within 30 days of each disaster in the electronic mass media (media). Articles were screened for dialysis related key words and classified into 3 categories according to reported potential for missing dialysis, missed dialysis or death.

Results: Of 887 natural disasters from 2000-2015, 120 had at least 1 reported death (total 4,383 deaths). Hurricanes and winter storms had the highest impact on dialysis patients with 5 reported deaths. Of 19 hurricanes incidents, 13 articles referred to dialysis, reporting 7 dialysis disruptions, 4 dialysis deaths and 12 instances of potential disruptions to dialysis. Only 1 of the 61 deaths reported during 3 winter storms was dialysis related, with 2 instances of dialysis disruptions and 3 instances with potential for dialysis disruption. Tornadoes, which occurred most often and resulted in the second highest mortality had no coverage in the media during its aftermath.

Variable	Number	Deaths	Articles with dialysis disruptions	Instances of Dialysis Death	Instances of Dialysis Disruptions	Potential For Dialysis Disruptions
Hurricanes	19	2,702	13	4	7	12
Tornadoes	84	1,454	0	0	0	0
Earthquakes	2	3	0	0	0	0
Floods	11	162	0	0	0	0
Tsunami	1	1	0	0	0	0
Wildfires	0	0	0	0	0	0
Winter Storms	3	61	5	1	2	3
Total	120	4,383	18	5	9	15

*Dialysis Death: Death due to disaster related disruption to dialysis

Conclusions: Based on media reports, hurricanes and winter storms are major contributors of treatment disruption and mortality in patients on dialysis. Media reports can help identify the magnitude of disruption to dialysis operations as well as deaths.

FR-PO392

A Comparison of Physician Reporting versus Computer Algorithms for CMS Data Reporting on Form CMS-2728 Mohammed Said Malas,[1,2] Ranjani N. Moorthi,[1] Jon D. Duke,[2] Sharon M. Moe.[1] *[1]IU, Indianapolis, IN; [2]RI, Indianapolis, IN.*

Background: The CMS-2728 form (ESRD Medical Evidence Report) assesses 23 comorbidities chosen to reflect poor outcomes and increased mortality risk. Previous studies have questioned the validity of physician data entry on forms CMS-2728 and the relationship to hard outcomes. We hypothesize that reporting of comorbidities by a computer algorithm identifies more comorbidities and therefore is superior to physicians' completion of the forms.

Methods: We collected data from CMS-2728 forms for all 296 patients who had incident ESRD diagnosis and received chronic dialysis between 2005 and 2014 at Indiana University outpatient dialysis centers. We analyzed patients' data from electronic records systems that collated information from multiple sources. Previously utilized computer algorithms or natural language processing was used to extract data on 10 comorbidities (Table) for a period of up to 10 years prior to ESRD incidence. These algorithms incorporate billing codes, prescriptions, and other elements that are relevant to each comorbidity. We compared the presence of these comorbidities on the forms to the determined presence according to the algorithms.

Results: The computer algorithms had higher reporting of comorbidities compared to physician completion of the forms (Table). This remained true when decreasing the data span to one year and using only single health center data sources.

Comorbidity	Computer algorithms		Physician completed forms		p-value
	% Present	% Absent	% Checked	% Unchecked	
CHF	44.3	55.7	16.9	83.1	<0.01
DM	57.4	42.6	36.8	63.2	<0.01
HTN	95.3	4.7	88.9	11.1	<0.01
CAD	28	72	9.8	90.2	<0.01
COPD	14.5	85.5	5.4	94.6	<0.01
Alcohol abuse	12.8	87.2	3.7	96.3	<0.01
Cancer	15.9	84.1	6.1	93.9	<0.01
Substance abuse	27.7	72.3	4.4	95.6	<0.01
CVA	11.1	88.9	6.1	93.9	<0.01
Inability to ambulate	6.8	93.2	3	97	<0.05

Conclusions: Data reporting using computer algorithms may increase the capture of comorbidities for form CMS-2728 which may result in more accurate standardized mortality ratio for dialysis units and improve quality reporting.

Kidney Dashboard: An Integrated Support Tool for Clinical Care and Research Involving Kidney Patients Jamie S. Hirsch,[1,2] Hojjat Salmasian,[2] Amy Y. Chan,[3] David Vawdrey,[3,2] Matthew Fred,[3] Krzysztof Kiryluk.[1] *[1]Div of Nephrology, Dept of Medicine, Columbia Univ, New York, NY; [2]Dept of Biomedical Informatics, Columbia Univ, New York, NY; [3]NewYork-Presbyterian Hospital, New York, NY.*

Background: Large amounts of data are contained in electronic health records (EHR), and retrieval of relevant information for nephrology patients is cognitively complex and time-consuming. This results in inefficiencies, missed opportunities to improve care, and difficulty adhering to complex clinical guidelines. We developed a Kidney Dashboard, an integrated tool that gathers and analyzes information to facilitate the care and research of kidney patients.

Methods: Relevant clinical data were catalogued and categorized, including visit history, billing data, vital signs, labs, imaging, pathology, and medications. We automated generation of derived data, such as estimation and trending of eGFR, proteinuria, and automated CKD staging. We implemented a comprehensive rule-based alert system based on KDIGO guidelines to provide real-time clinical decision support.

Results: The Dashboard was created within the clinical information system at NewYork-Presbyterian Hospital, incorporating inpatient and outpatient data from multiple sources. It uses a tile layout, where each tile represents a relevant section of data that matches clinician workflow, e.g., renal function, anemia, bone and mineral metabolism, glomerulonephritis, etc. Repeat eGFR and proteinuria data are presented as interactive longitudinal graphs. The Dashboard integrates delivery of comprehensive stage-specific decision support and creates a portable phenotypic patient profile for genetic and epidemiologic research in kidney disease.

Conclusions: The Kidney Dashboard aims to improve care and facilitate research by consolidating all relevant EHR data at the point-of-care and generating phenotypic profiles of kidney patients. This project promotes precision nephrology, exemplifying the next generation of "smart" EHR tools. Following its public release, effectiveness of the Dashboard will be studied in focus groups and by time-motion studies and audit log analyses. The improvement in adherence to KDIGO guidelines will be tested prospectively.

FR-PO394

Forecasting a Renal Prognosis of IgA Nephropathy Using Machine Learning: Validation Study Hajeong Lee,[1] Junhyug Noh,[2] Hyosang Kim,[3] Won Seok Yang,[3] Yon Su Kim,[1] Dong Ki Kim.[1] *[1]Internal Medicine, Seoul National Univ Hospital; [2]Computer Science and Engineering, Seoul National Univ College of Engineering; [3]Internal Medicine, Asan Medical Center.*

Background: We aimed to develop and validate individual outcome prediction models in IgAN patients using machine learning.

Methods: We included adult IgAN patients from Seoul National University Hospital (SNUH, n = 1,540) and Asan Medical Center (AMC, n = 1,044) at the time of renal biopsy. They were divided into development (followed up ³10 years) and prediction (follow up <10 years) sets, respectively. The outcome was 10-year renal survival (10YRS) probability. We developed prediction models from SNUH test set by using logistic regression (LR) with Lasso method, a classification and regression tree (CART), and neural network (NN) using 16 clinico-pathologic variables. We also used bagging, random forest (RF) and boosting for ensemble learning. Finally, those models were validated internally in SNUH prediction set and externally in AMC development and prediction sets.

Results: Considering missing data, 1,514 and 847 patients were included from SNUH and AMC cohorts. In the LR model, eGFR, hemoglobin, proportions of GS and SS, interstitial fibrosis (IF) were selected as predictors for ESRD. In the CART model, eGFR 53.3 ml/min/1.73m^2 was proved to be a watershed for 10YRS, followed by, proportion of GS and SS, IF, hemoglobin and proteinuria, sequentially. In addition, the ensemble learners showed good performance (accuracies of bagging, 0.868; RF, 0.874; boosting, 0.862). Those individual learners were validated internally with good performance (sensitivities of LR, 0.855; CART, 0.921; NN, 0.952; bagging, 0.857; RF, 0.921; boosting, 0.921). And finally, we proved the robustness of those models from external validation. Good performances of both development (sensitivities of LR, 0.847; CART, 0.867; NN, 0.855; bagging, 0.852; RF, 0.872; boosting, 0.851) and prediction sets (sensitivities of LR, 0.980; CART, 0.902; NN, 0.941; bagging, 0.882; RF, 0.902; boosting, 0.922) were showed.

Conclusions: We developed robustness of prediction models using machine learning for the individual's likelihood of 10YRS in IgAN with both internal and external validation.

FR-PO395

Quantifying the Gender Reimbursement Gap in Nephrology Sadeem Ali, Xiangming Fang, Pankaj Jawa, Tejas P. Desai. *Nephrology, East Carolina Univ, Greenville, NC.*

Background: 2015 Medscape Compensation Report suggests that female providers earn less than male providers but the sample size was 19657; only 1% Nephrologists. To analyze the financial disparities, we compared total Medicare reimbursements paid to males & females.

Methods: We obtained reimbursement data from 2014 Medicare Provider Utilization & Payment Data Physician Public Use File. We consolidated all reimbursements by NPI number & categorized them by specialty & sex. We adjusted reimbursement differentials against number of Medicare beneficiaries seen & services provided. Linear regression models were used to compare reimbursements.

Results: We analyzed 246,996 providers in 13 specialties; 3% were Nephrologists. Female Nephrologists were reimbursed less $41,776.96 (unadjusted); the 6th worst female-to-male reimbursement differential. In the adjusted analysis, female Nephrologists had the worst reimbursement differential: less $17,971.66.

	Unadjusted	Lower	Upper	Adjusted	Lower	Upper
All	34125.68	34991.61	33259.79	19980.23	20599.45	19361.00

Female Reimbursement Deficits ($). Lower & Upper Refer To 95% Confidence Interval Bounds.

Conclusions: When adjusted for the number of beneficiaries seen & services provided, female Nephrologists endure the largest reimbursement gap by sex in any specialty. Steps should be considered to close his gap.

FR-PO396

Protein Engineering for Renal Delivery of Molecular Therapies Pan Liu, Jing Jin. *Dept of Medicine-Nephrology/Hypertension, The Feinberg School of Medicine, Chicago, IL.*

Background: Targeted delivery of therapeutic enzymes to the kidney is desirable for treatment of renal diseases and beyond. Previously, approaches that exploit the renal excretion of low–molecular weight proteins (LMWP) have been attempted. However, these carriers can only deliver chemical compounds, and their efficiency is further hampered by fast renal clearance. In order to deliver enzyme cargos, we designed carrier proteins for specific and long-lasting renal delivery. We engineered a fusion protein comprised of a kidney-targeting polybasic tag (PBT) and an Fc segment for extended stability.

Methods: PBT-Fc and Fc-only control were produced as recombinant proteins. We used Duramycin as an LWMP control for alternative means of renal targeting through excretion. The probes were then separately labeled with a radionuclide ^{99m}Technetium (^{99m}Tc) tracer. Following i.v. injection of the probes to rats, we performed SPECT in whole body scanning. Radiographs were obtained in a time series for up to 1 hour. In parallel, we performed histology studies of kidney sections to determine the sub-anatomical patterns of the injected probes.

Results: Prominent and sustained kidney localization of ^{99m}Tc-PBT-Fc (>95%) was observed by SPECT, a pattern in contrast to that of the ^{99m}Tc-Fc control that was mainly in blood circulation during the course of observation (only <5% is in the kidney). ^{99m}Tc-

Duramycin reached the kidney quickly and then followed through urinary excretion to the bladder. By 20 minutes less than 5% remained in the kidney. The imaging results were consistent with IHC findings from mouse kidney following probe injections, which shows the PBT-Fc, but not Fc-alone, binding the glomeruli and tubule basement membrane shortly after injection. PBT-Fc sustained in the kidney for at least 10 days.

Conclusions: Our engineered PBT-Fc carrier exclusively targets kidney through binding to the glomeruli and tubule basement membrane. This recombinant probe also achieves long-lasting kidney retention (days as compared to minutes for LMWP), yet another desirable property for targeted therapeutic delivery. This vehicle will potentially be useful for delivery of molecular therapies, particularly enzyme proteins, to the kidney.

FR-PO397

Dynamic Culture on an Orbital Shaker Alters the Phenotype of Primary Human Renal Tubular Epithelial Cells Nicholas J. Ferrell,[1] Jin Cheng,[1] Simeng Miao,[2] William Henry Fissell.[1] *[1]Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; [2]Biomedical Engineering, Vanderbilt Univ, Nashville, TN.*

Background: Primary cells cultured *in vitro* gradually lose features characteristic to the *in vivo* cell type, variously termed "senescence" or "culture stress." Culture conditions that help maintain cell-specific phenotype are advantageous for cell biology and tissue engineering. Here we evaluated the phenotype of primary renal tubular epithelial cells after applying apical fluid shear stress using an orbital shaker.

Methods: Human renal tubular epithelial cells were isolated from donor kidneys not suitable for transplant. Cells were cultured on Transwell inserts under static conditions or on an orbital shaker at a frequency producing fluid shear stresses of 2 dyn/cm^2. Transepithelial resistance was measured daily. After 2 weeks in culture, cell density was analyzed by counting DAPI stained nuclei, and expression of tubule-specific markers was measured by PCR and western blotting.

Results: Dynamic culture significantly increased steady state transepithelial resistance from 344±31 to 544±32 Ω-cm^2 ($p<0.001$) and resulted in a 21.5±2.1% ($p<0.001$) increase in cell density. Gene expression of tubule epithelial cell markers (GGT1, COL4A1, COL4A2, NHE3, and NAPP2) increased with fold changes in expression of 4.3±0.3, 4.1±0.3, 3.1±0.2, 2.1±0.4, and 1.9±0.2, respectively. Cells grown under shear also showed increased protein expression of gamma-glutamyl transpeptidase.

Conclusions: Primary renal tubular epithelial cells grown on an orbital shaker with physiological levels of fluid shear stress appear to express proximal tubule markers more than cells grown in static conditions. This may be due to increased nutrient delivery and waste removal with improved mixing at the apical brush border, or due to specific gene regulation related to mechanotransduction. Further mechanistic insight may allow investigators to develop improved *in vitro* culture systems for cell biology and tissue engineering and more accurate *in vitro* models of disease.

FR-PO398

CRISPR/Cas9-Mediated Site-Specific Mutation in Rat Angiomotin Gene via Direct Injection of One-Cell Embryos Yaochun Zhang,[1] Zakir Hossain,[2] Bo Lan,[1] Chang-Yien Chan,[1] Hui Kim Yap,[1] Kar Hui Ng.[1] *[1]Dept of Paediatrics, National Univ of Singapore, Singapore; [2]Cancer Science Inst of Singapore, National Univ of Singapore, Singapore.*

Background: Genetically modified animals represent a crucial tool for understanding gene function in development and disease. The recently developed CRISPR/Cas9 system is an efficient gene-targeting technology to generate genetically modified animals. We have performed exome sequencing in a Singapore Chinese family with X-linked recessive membranous nephropathy associated with Fanconi syndrome and anti-tubular basement antibodies, and identified AMOT, coding for angiomotin, as a novel candidate gene with a putative disease-causing mutation p.S50G in the N-terminal of the p130-AMOT isoform. Preliminary work confirmed the expression of angiomotin in renal tubular cells. This study aimed to introduce the mutation into rat genome via direct injection of CRISPR/Cas9 into one-cell embryos, establishing rat models for downstream pathological studies.

Methods: The tracrRNA:crRNA fused single guide RNA (sgRNA, 20ng/µl), together with Cas9 protein (40ng/µl) and a single-stranded oligonucleotide (ssODN, 3ng/µl), which encodes the p.S50G mutation of angiomotin and serves as template for HR-mediated repair, were introduced into the rat pronucleus via microinjection. Pups produced from the injected embryos were first detected by mismatch-sensitive T7 endonuclease I digestion. Animals carrying mutations were sequenced to determine the precise sequence.

Results: In the 32 survived pups, one (3.1%) founder rat was identified to carry the heterozygous mutation. After crossing F0 with a wild-type rat, ten F1 rats were delivered, of which four males (40%) were carrying the mutation on their X chromosomes, while 2 (20%) were heterozygous females. No phenotype data is available currently as the animals are only three weeks old. Homozygous female rats are expected to be produced by crossing between the F1 animals.

Conclusions: In conclusion, a heritable site-specific mutation was successfully introduced into the rat genome with the CRISPR/Cas9 system. This one-step method of generating site-specific mutations in rats will greatly accelerate the *in vivo* study of gene functions.

FR-PO399

Double Transduction of a Cre/LoxP Lentiviral Vector: A Simple Way to Generate Cell-Specific Knockdown Mice Shin-Wook Kang, Bo Young Nam, Meiyan Wu, Tae-Hyun Yoo. *Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Genetically engineered mice have been used to elucidate the function of specific genes. Transgenic mice generated by conventional knockout techniques using oocytes or embryonic stem cells are most commonly used to downregulate genes, but this method has certain limitations. Therefore, a novel method to knock down specific genes in a cell specific manner in adult mice was devised by lentivirus (LV)-assisted transfer of short hairpin RNA.

Methods: In vitro, the LV suspension containing LV-Hoxb7 Cre and/or LV-Aquaporin 3 shRNA (shAQP3) was added to cultured mouse renal collecting duct cells (CDs) and mouse mesangial cells (MMCs). In vivo, first, LV-Hoxb7 Cre was injected into the loxP-EGFP mice to check the Hoxb7 promoter efficiency. Second, LV-loxP shAQP3 was injected into the Hoxb7 Cre transgenic mice to check shAQP3 function. Third, consecutive injections of LV-Hoxb7 Cre and LV-loxP shAQP3 were made to C57BL6/J mice.

Results: In vitro, LV-Hoxb7 Cre worked only in CDs due to the presence of Hoxb7 in CDs but not in MMCs. Furthermore, combined infection of CDs with LV-Hoxb7 Cre and LV-loxP shAQP3 significantly inhibited the protein expression of AQP3 along with the disappearance of EGFP protein expression, suggesting that LV-Hoxb7 Cre and LV-loxP shAQP3 used in this study worked together effectively. In vivo, kidney CD-specific AQP3-knockdown mice were generated by consecutive injection of LV-Hoxb7 Cre and LV-loxP shAQP3 in adult C57BL6/J mice. In mice treated with LV-Hoxb7 Cre alone, mCherry protein expression occurred only in CDs, while LV-loxP shAQP3 injection alone led to an increase in EGFP expression in all cells. In the kidney, AQP3 expression in mice injected with LV-Hoxb7 Cre or LV-loxP shAQP3 alone did not differ, but consecutive injection of LV-Hoxb7 Cre and LV-loxP shAQP3 significantly reduced AQP3 expression. However, the expressions of AQP3 in other organs did not differ between the groups.

Conclusions: Double transduction of Cre- and loxP-based LV can be a simple way to generate cell-specific knockdown mice, and this method may also be applicable to other species.

FR-PO400

Local Delivery of Interleukin-10 via Injectable Hyaluronic Acid Hydrogels to Prevent Local and Systemic Injury in Ischemic Acute Kidney Injury Danielle Soranno,[1] Chris Altmann,[2] Sarah Faubel,[2] Ana Andres-hernando.[2] *[1]Pediatrics & Bioengineering, Nephrology, Univ of Colorado, Aurora, CO; [2]Medicine, Nephrology, Univ of Colorado, Aurora, CO.*

Background: AKI is pro-inflammatory and causes systemic complications via IL-6. Here, we use injectable hyaluronic acid (HA) hydrogels to deliver IL-10, an anti-inflammatory cytokine, to improve local and systemic outcomes of AKI.

Methods: Four treatment groups were followed for 28 days following AKI (15 µL of therapy delivered 3 days status-post AKI), and compared to healthy and untreated AKI controls (n=5): IL-10 in saline delivered under the left kidney capsule (LK IL-10); IL-10 suspended in HA delivered subcutaneously (SQ gel/IL-10); HA with or without IL-10 injected under the left kidney capsule (LK gel, LK gel/IL-10); HA hydrogels were developed as previously reported. Serial measurements of blood urea nitrogen and creatinine were followed at 1, 4, and 28 days. Serum IL-6 was measured at sacrifice. Immunohistochemistry (IHC) was performed to identify collagen type III deposition. Positive cells were quantified (20 images/section, in cortex). ANOVA with Dunnett's posthoc was used to determine significance.

Results: All treatment groups normalized BUN, Cr and serum IL-6 by day 28 while the untreated AKI cohort had a persistent increase in BUN, Cr and IL-6. All treatment groups showed a significant reduction in collagen deposition in both left and right kidneys compared to untreated AKI, with variable effect depending on the mode of HA/IL-10 delivery.

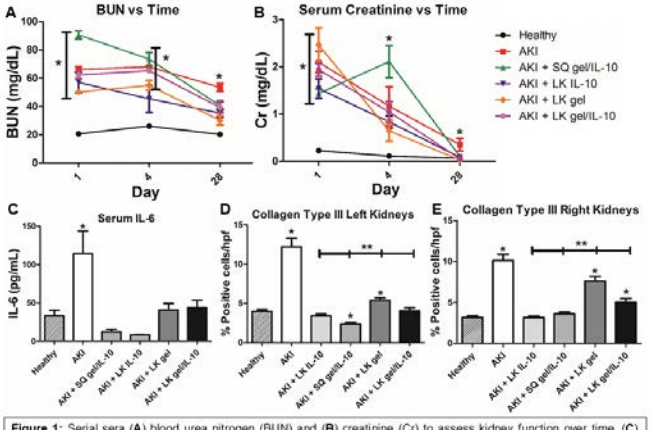

Figure 1: Serial sera (**A**) blood urea nitrogen (BUN) and (**B**) creatinine (Cr) to assess kidney function over time. (**C**) Serum IL-6 to assess systemic inflammation 28 days following AKI. IHC for Collagen type III in (**D**) left and (**E**) right kidneys. *, ** indicates statistical significance compared to healthy or AKI control, respectively. n = 5, $p < 0.01$.

Conclusions: Injectable HA hydrogels can be used to deliver IL-10 and improve local and systemic outcomes of ischemic AKI. Therapy improved renal function, reduced collagen deposition, and reduced systemic IL-6 28 days following AKI. HA alone improved outcomes; the addition of IL-10 to the HA resulted in further histological improvement.

Substrate Stiffness Regulates Renal Epithelial Cell Cilia Formation via Autocrine TGFβ Signaling

Mingfang Ao,[1] Jin Cheng,[1] Nicholas J. Ferrell,[1] H. David Humes,[3] Shuvo Roy,[2] William Henry Fissell.[1] *[1]Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; [2]Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA; [3]Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: The primary cilium senses the extracellular environment. Malformation of primary cilia has been shown to result in kidney disease. Although much is known regarding ciliogenesis, the role of mechanical features of the microenvironment in cilia formation is poorly understood.

Methods: Human primary proximal tubule epithelial cells (HRECs) and LLC-PK1 cells were plated on collagen-coated polyacrylamide gels with different stiffness (0.5 KPa, 1 KPa, 10 KPa and 40 KPa) and grown for 5 to 7 days. Cilia formation was analyzed by immunofluorescence staining of AC-tubulin followed with microscopy imaging. Protein expression was measured by immunoblotting. Recombinant TGFβ 1 and an inhibitor of TGFbRII SB431542 were used for TGFβ signaling modulation. LiCl was utilized to stimulate P-GSK3b.

Results: Stiff hydrogels (10 KPa and 40 KPa) gave rise to higher ciliary density than compliant gels (0.5 KPa and 1KPa) did (60% vs 20%). Furthermore, this phenotype could be altered by manipulation of transformation growth factor beta (TGFβ) signaling: addition of TGFβ 1 could increase the cilia frequency even when the cells were on compliant gels; similarly, inhibition of TGFβ receptor II impairs cilia formation in the context of stiff substrates. Further supporting a role for TGFB, substrate stiffness was associated with increased SMAD2 and GSK3B phosphorylation. Incubation with LiCl also increased GSK3B phosphorylation and cilia formation independent of TGFβ.

Conclusions: Substrate stiffness determines cilia formation through TGFβ signaling via downstream GSK3β phosphorylation. This work highlights that substrate mechanical properties have a strong influence on markers of differentiation. This has relevance for tissue engineering efforts and also suggests a mechanism of disease progression in the scarred kidney. This may broaden researches on kidney disease and contribute to disease therapy.

An Additive Role of Microfluidics on KLF 15-Induced Differentiation of Human Primary Podocyte

Seung Hee Yang,[1] Eunjin Bae,[2] Sejoong Kim,[2] Kwon Wook Joo,[1,2] Chun Soo Lim,[1,2] Yon Su Kim,[1,2] Dong Ki Kim.[1,2] *[1]Kidney Research Inst; [2]Internal Medicine, Seoul National Univ College of Medicine, Seoul.*

Background: Podocyte de-differentiation is one of major problems during the process of primary podocyte culture. Recently, much interest has been focused on the topic; yet lengthy podocyte differentiation process hinders a progress. *Krüppel*-like factor 15 (KLF 15) was reported to be a novel transcriptional regulator of podocyte differentiation and its expression was increased by retinoic acid (RA) which promotes the differentiation of podocytes. But, the duration of podocyte differentiation process remains long. Here, we present a novel in vitro protocol to induce podocyte differentiation.

Methods: To mimic in vivo biological environment of glomerulus, a polydimethly siloxane (PDMS) microfluidic device was used. The human primary podocytes were cultured in the 500 mm by 130 mm microfluidic channel and were stimulated with a laminar fluidic shear stress of 0.5 dyn/cm^2 for 5 days. Various dose of RA was used to promote podocyte differentiation.

Results: In this research, we were able to reduce the time required for podocyte differentiation with higher shear stress and higher dose of RA. A couple of tests were conducted to verify the podocyte differentiation through the protocol. First, the phenotype of podocytes changed from cobblestone like shape to arborized cells. Through immunofluorescence staining, the increased expression of cytoplasmic synaptopodin and intercellular junction ZO-1 was confirmed. Moreover, KLF 15 expression was also increased.These molecules were also quantified with mRNA expression through real-time PCR. The size of podocytes became larger and the height of podocytes increased by a factor of 2.3 fold. Lastly, the podocytes aligned with the direction of flow.

Conclusions: In conclusion, we were able to promote podocyte differentiation in the shorter processing time with microfluidics and RA. Yet, more effort to mimic biological aspects of kidney such as complex structure with multiple cell layers and round surface is necessary.

FR-PO403

CCL18 Correlates with Disease Activity in ANCA-Associated Necrotizing Glomerulonephritis

Silke R. Brix,[1] Christian F. Krebs,[1] Martin Busch,[2] Thorsten Wiech,[3] Ulf Panzer,[1] Rolf A. Stahl.[1] *[1]III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Germany; [2]Klinik für Innere Medizin III, Universitätsklinikum Jena, Germany; [3]Inst für Pathologie, Universitätsklinikum Hamburg-Eppendorf, Germany.*

Background: Microarray analysis of renal tissue from patients with antineutrophil cytoplasmic antibody (ANCA)-associated necrotizing glomerulonephritis (GN) revealed the CC chemokine ligand 18 (CCL18) as the highest up-regulated chemokine. The renal production of CCL18 was associated with fresh glomerular lesions and impairment of renal function. The cellular sources of CCL18 were identified as macrophages and dendritic cells. CCL18 serum levels were elevated in patients with newly diagnosed ANCA GN as well. In order to test whether CCL18 might serve as a biomarker of relapsing renal ANCA disease, we prospectively analyzed CCL18 serum levels.

Methods: Hundred thirty-five patients with biopsy proven ANCA GN were prospectively analyzed for CCL18 serum levels. Patients included in the study were in remission on maintenance therapy (n=117) or without immunosuppressive treatment (prednisolone 5mg or less was accepted) (n=18). Serum levels of CCL18 were measured by ELISA every three months. Renal relapse was defined as either rising serum creatinine with urinary red cell casts or biopsy-confirmed active ANCA-associated glomerular lesions (i.e. fibrinoid necrosis and/or cellular crescents) accompanied by an intensification in immunosuppressive treatment.

Results: During a mean follow up time of 11.6 ± 8.3 months, 16 patients developed a renal relapse. CCL18 levels were higher in relapsing patients when compared with patients who remained in remission ($p<0.0001$; 167.50 ± 85.04 ng/ml vs. 83.17 ± 46.38 ng/ml). CCL18 serum levels increased at the time of relapse and decreased after immunosuppressive therapy was restarted or intensified (n=16; ANOVA; $p<0.001$).

Conclusions: CCL18 serum levels are associated with disease activity in patients with ANCA GN and might serve as a marker of renal relapses in the surveillance of these patients.

FR-PO404

Prognostic Value of Persistent Heamaturia and Proteinuria in ANCA-Associated Vasculitis: Data from the European Vasculitis Study Group (EUVAS) Therapeutic Trials

Alexandre Karras,[1,3] Thomas F. Hiemstra,[2,3] Rachel B. Jones,[2,3] David R.W. Jayne.[2,3] *[1]Nephrology, HEGP Hospital, Paris, France; [2]Nephrology, Addenbrooke's Hospital, Cambridge, United Kingdom; [3]On behalf of the EUVAS Study Group.*

Background: Renal involvement is frequent ANCA-associated vasculitis (AAV), due to crescentic glomerulonephritis (CGN). Heamaturia (Hu) and proteinuria (Pu) are detected during the initial and active phase of CGN but the prognostic value of the persistence of these urinary abnormalities during the remission phase of AAV is still controversial.

Methods: Data were combined from three EUVAS trials (IMPROVE, RITUXVAS, MYCYC), providing data for Hu and Pu at month 6 (M6) following initiation of immunosuppression and patient follow-up until month 18 (M18). Hu was defined as the presence of >10 RBC/mm3. Proteinuria was evaluated by protein-to-creatinine ratio (PCR, g/mmol).

Results: Data concerning 337 patients were available for analysis. ANCA specificity (PR3/MPO) was 58/37%, renal involvement was present in 73% of cases and initial mean eGFR was 46±32 ml/min/1.73m2. Hu was still positive at M6 in 27% of cases, although 96% of patients were in AAV remission. Positivity of Hu at M6 was associated with more severe initial nephropathy but was not predictive of renal dysfunction at last FU (mean eGFR at M18 was respectively of 55±24 and 60±24 ml/min for Hu+ and Hu- patients, p=NS). Proteinuria at M6 was <0.03 g/mmol in 53% of cases, between 0.03 and 0.1 g/mmol in 25%, >0.01 g/mmol in 22%. Among patients with M6 Pu >0.1 g/mmol, 29% had CKD stage 4 or 5 at M18, vs 3.5% and 11.5% respectively for patients with M6 PCR <0.03 and 0.03-0.1 g/mmol. Multivariate analysis using a mixed effects model demonstrated that decrease of eGFR during follow-up was independently associated with age ($p<0.001$), baseline eGFR ($p<0.001$) and M6 proteinuria ($p=0.002$), but not with M6 haematuria ($p=0.284$) nor ANCA specificity ($p=0.82$).

Conclusions: Persistence of micro-hematuria during the remission phase of AAV is associated with more severe initial renal involvement but does not predict poor renal outcome. Degree of proteinuria at M6 reflects more severe kidney damage and is an independent predictor of CKD progression in AAV nephropathy.

FR-PO405

ANCA Associated Vasculitis: Safe and Effective Induction of Remission with Low Dose Cyclophosphamide, Rituximab, and Reduced Exposure to Glucocorticoids

Frank B. Cortazar, Karen A. Laliberte, Andrew P. Murphy, Katherine M. Cosgrove, William Franklin Pendergraft, John Niles. *Renal Associates, Massachusetts General Hospital, Boston, MA; Kidney Center, Univ of North Carolina (UNC), Chapel Hill, NC.*

Background: Rapid induction of remission in ANCA-associated vasculitis(AAV) is essential to prevent irreversible organ damage.Current regimens use glucocorticoids(GC) combined with either cyclophosphamide(CYC) or rituximab(RTX).To effectively induce remission while minimizing GC exposure,we devised a standard induction(SI) protocol that combines RTX,low-dose bridging oral CYC,and a rapid GC taper.

Methods: Retrospective analysis of AAV pts treated w/ new SI regimen:RTX 1gm Q2wk x 2 doses,oral CYC 3mg/Kg/d x1 wk and 1.5mg/Kg/d x2 mths(adj for eGFR),and pulse solumedrol followed by a rapid prednisone(pred) taper to £15mg/d by 5wks. Remission defined as BVAS-WG 0 and pred dose ≤7.5mg/d.Pts received SI alone or SI+ plasma exchange (PE).

Results: 74 pts treated with SI and 35 pts w/SI+PE (table1).Time to remission in the SI and SI+PE was 117±53 and 122±39 days,respectively (p=0.67).Cumulative incidence plots(Figure 1). Among survivors,100% of SI and 97% of SI+PE achieved remission. 3 pts (4%) in SI and 1 (3%) in SI+PE died during induction.There were 0.04 treatment-related serious adverse events/pt month in both groups.

Baseline	SI	SI+ PE	p value
Age	61 ± 16	65 ± 17	0.24
% Women	62	49	0.17
% MPO	67	60	0.35
Baseline Cr (mg/dL)	1.8 ± 1.1	4.9 ± 1.9	<0.01
% Dialysis Dependence	1	11	<0.01
Initial BVAS-WG	6.3 ± 2.8	8.7 ± 3.3	<0.01

Conclusions: RTX with low-dose bridging CYC allows for successful induction of remission in essentially all AAV pts while attenuating exposure to high dose GC.Treatment-related adverse events were minimal.Our data provide an impetus for a randomized trial comparing this new regimen with the standard of care.

Reduced Risk of Cancer with Substitution of Cyclophosphamide with Azathioprine for Maintenance Treatment of ANCA Associated Glomerulonephritis

Sanjeevan Sriskandarajah,[1] Knut Aasarod,[2] Tor Aage Myklebust,[3] Anna Reisaeter,[4] Rune Bjoerneklett.[1,5] *[1]Renal Research Group, Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway; [2]Dept of Nephrology, St. Olav Univ Hospital, Trondheim, Norway; [3]Cancer Registry of Norway, Oslo, Norway; [4]Norwegian Renal Registry, Oslo Univ Hospital Rikshospitalet, Oslo, Norway; [5]Dept of Medicine, Haukeland Univ Hospital, Bergen, Norway.*

Background: ANCA associated vasculitis (AAV) is associated with an increased risk of cancer and a dose-dependent oncogenic effect of cyclophosphamide (CYC) appears to be a major explanatory mechanism. The concept that Azathioprine (AZA) can safely substitute for CYC in maintenance treatment of AAV was demonstrated in the CYCAZAREM study (2003) and has been adopted by all hospitals treating ANCA associated glomerulonephritis (AAGN) in Norway. In the present study, risk of cancer in patients with AAGN using CYC versus AZA for maintenance treatment has been compared.

Methods: Patients diagnosed with AAGN registered in the Norwegian Kidney Biopsy Registry 1988-2012 were included. The study cohort was linked to the Cancer Registry of Norway. Standardized incidence ratios of cancer were calculated. A competing risk regression model, using death as a competing risk, and with adjustment for; age, gender, ANCA category and kidney transplantation were used to compare the CYC and AZA groups regarding risk of cancer. The observation period was time from diagnostic kidney biopsy to death, first-time cancer or end of year 2013.

Results: We identified 485 patients with AAGN for analysis. Mean age was 58 years (SD 17 years) and 267 (55%) were males. Mean duration of follow-up was 7.2 years (SD 6 years and range 0.0-24.3 years). During follow-up 53 cancers (first cancer, all-sites) appeared, SIR 1.26 (0.97-1.67). In the CYC maintenance group 49 cancers appeared, SIR 1.40 (1.06-1.87) and in the AZA maintenance group 4 cancers, SIR 0.57 (0.22-1.98). Risk of cancer was significantly lower in the AZA as compared to the CYC maintenance group (p<0.05), estimated risk reduction being approximately 60%.

Conclusions: Substitution of CYC with AZA for maintenance treatment of AAGN is associated with significantly reduced risk of cancer.

FR-PO407

Double Positivity for ANCA and Anti-GBM Antibodies: Clinical Characteristics and Long-Term Outcomes of a Multi-Centre Cohort

Stephen Paul McAdoo,[1] Anisha Tanna,[1] Sophie Ohlsson,[2] Zdenka Hruskova,[3] Maria Weiner,[4] Jeremy B. Levy,[1] Vladimir Tesar,[3] Marten Segelmark,[4] Charles D. Pusey.[1] *[1]Imperial College London; [2]Lund Univ; [3]Charles Univ Prague; [4]Linkoping Univ.*

Background: Co-presentation with both ANCA and anti-GBM disease is a rare phenomenon. Current studies of such cases include small numbers and report variable outcomes. We aim to describe the clinical features and outcomes of a large cohort of contemporary patients identified from three large European centres.

Methods: This is a retrospective cohort study, which included patients with both ANCA and anti-GBM antibodies ('double-positive', DP) from three centres, who presented after 2000, and for whom at least 1 year follow-up data was available. We have compared parameters to patients presenting with 'single-positive' (SP) anti-GBM disease.

Results: We have identified 78 anti-GBM+ patients, of whom 37 (47%) were DP for ANCA (70% MPO, 27% PR3, 3% MPO+PR3). DP patients were older (mean age 63 vs 54 yrs, p=0.048) and had longer symptom duration before diagnosis (6 vs 2.5 wks, p=0.049). There were no differences in renal function, dialysis-requirement, or frequency of lung haemorrhage between groups, although DP patients had more chronic injury on renal biopsy (33% vs 7% tubular atrophy, p=0.001). SP and DP groups were treated similarly. There were no differences in early (3 month) or late (5 year) patient or renal survival (5 year survival 78% vs 81%, p=0.49), although DP patients had a significant risk of relapse (8 vs 0 relapses over median follow-up of 3.9 years, p=0.01) that in all cases was associated with recurrence or rising titre of ANCA.

Conclusions: This is the largest reported series of European patients with double seropositivity for ANCA and anti-GBM antibodies. Patient and renal-survival was comparable to SP anti-GBM disease, although DP patients have greater risk of relapse related to their ANCA status, and so require long-term follow-up and consideration of maintenance immunosuppression. DP cases had a longer prodrome of symptoms and evidence of chronic damage of renal biopsy, suggesting that ANCA-induced glomerular inflammation may precede and contribute to the development of anti-GBM disease.

FR-PO408

Pulse Methylprednisolone for Induction of Remission in Severe ANCA Associated Vasculitis Is Associated with an Increase in Adverse Events but No Improvement in Outcome

Dimitrios Chanouzas,[1] JulieAnne G. McGregor,[2] Alan D. Salama,[3] Wladimir M. Szpirt,[4] Neil Basu,[5] Matthew David Morgan,[1] Caroline J. Poulton,[2] Juliana Bordignon Draibe,[3] Elizabeth Krarup,[4] Paula I. Dospinescu,[5] Jessica Anne Dale,[1] William Franklin Pendergraft,[2] Keegan Lee,[3] Martin Egfjord,[4] Susan L. Hogan,[2] Lorraine Harper.[1] *[1]Univ of Birmingham, United Kingdom; [2]Univ of North Carolina Kidney Center; [3]Univ College London, United Kingdom; [4]Copenhagen Univ Hospital, Denmark; [5]Univ of Aberdeen, United Kingdom.*

Background: Intravenous pulse methylprednisolone (MP) is frequently used as part of remission induction in severe ANCA associated vasculitis (AAV). However, there are no studies assessing its efficacy in the setting of AAV, while treatment related complications remain the main source of morbidity.

Methods: We retrospectively analysed outcomes of 114 patients that presented with severe AAV at 5 large centers in the United Kingdom, United States and Denmark between 2000-2013. All patients received high dose oral corticosteroids, cyclophosphamide and plasma exchange. Rituximab treated patients were excluded. The chi square and Mann Whitney U tests were used for statistical analysis.

Results: Fifty-two patients received MP (median dose 1.5g over 3 days) in addition to standard therapy while 62 did not. Patient characteristics and disease severity were comparable between the two groups. There was no difference in survival at 3 months (MP: 94.2 vs non MP: 91.9%, p=0.633) or 12 months (84.6 vs 80.6%, p=0.579). Renal recovery amongst survivors (63.5 vs 72.6%, p=0.297) and relapse rates at 12 months (11.6 vs 8.6%, p=0.617) were similar. MP therapy was associated with more infections per patient at 3 months (0.7 vs 0.3, p=0.005) and more new onset diabetes (28.6 vs 6.6%, p=0.002).

Conclusions: Within the limitations of this study we found that the addition of MP to standard therapy for remission induction in severe AAV led to a significant increase in adverse events with no improvement in survival, renal recovery or relapse rates. Our results question the currently widespread use of MP in severe AAV and suggest that a randomised controlled trial is urgently needed in order to definitively address this issue.

FR-PO409

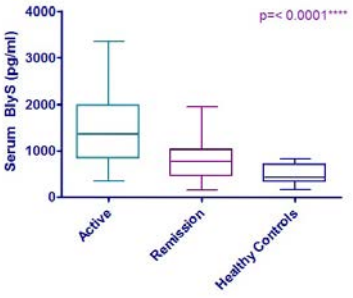
Serum B Lymphocyte Stimulator (BlyS) Levels as Markers of Disease Activity in Anti-Neutrophil Cytoplasm Antibody (ANCA) Associated Vasculitis (AAV)

Anisha Tanna, Stephen Paul McAdoo, Frederick W.K. Tam, Charles D. Pusey. *Imperial College, London.*

Background: B lymphocyte stimulator (BlyS) has been implicated in the pathogenesis of AAV. Previous studies have shown elevated levels in active disease, and following anti-CD20 therapy. Antineutrophil cytoplasm antibodies (ANCA) are not reliable predictors of disease activity and relapse and alternative markers are needed in order to tailor immunosuppressive therapy. The aim of this study was to determine the clinical significance of serum BlyS levels in our patients with AAV.

Methods: Serum samples were obtained from patients with AAV at our centre, and BlyS levels detected using sandwich ELISA. Clinical data were obtained by review of patient records.

Results: Samples were collected from 68 patients with AAV and 13 healthy controls. Thirty one patients were male, 44 Caucasian and 21 Indoasian. Fifty patients had granulomatosis with polyangiitis, 13 patients had microscopic polyangiitis and 5 had eosinophilic granulomatosis with polyangiitis. Significantly higher BlyS levels were found in patients with active disease than those in remission and healthy controls.



Thirty seven patients who had been treated with Rituximab had significantly higher BlyS levels (p<0.0001). Eighteen patients had relapsed at 1 year following recruitment. These relapsing patients had significantly higher BlyS levels than those patients who did not relapse (p=0.0016).

Conclusions: This study supports the role of BlyS in the pathogenesis of AAV. BlyS levels could be used as markers of disease activity and predictors of relapse. With increased use of rituximab in AAV, further studies are needed to assess the impact of B cell depletion on B cell survival factors. These findings highlight the potential role for BlyS antagonists in the maintenance of remission of AAV.

FR-PO410

Predictors of Renal Histopathology in Antineutrophil Cytoplasmic Antibody Associated Glomerulonephritis Sophia Lionaki,[1] Clio Mavragani,[2] George Liapis,[3] George Somarakis,[4] John N. Boletis,[1] Alexandros Drosos,[4] Athanasios Tzioufas,[2] Haralampos Moutsopoulos.[2] *[1]Nephrology, Laiko Hospital, Athens, Greece; [2]Pathophysiology, Univ of Athens, Greece; [3]Pathology, Laiko Hospital; [4]Rheumatology, Univ of Ioannina.*

Background: Prompt, aggressive therapy is vital foranti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN). In this regard, we aimed to identify predictors of distinct renal histopathological classes at the time of clinical diagnosis.

Methods: An inception cohort of patients with biopsy proven ANCA-associated GN was studied retrospectively. Demographics, clinical, laboratory, serological and radiological parameters were analyzed. Patients were classified on the basis of renal histopathology, according to the report by Berden et al (JASN 2010) for ANCA-associated GN by a renal pathologist into: focal class, crescentic class, mixed class and sclerotic class. A risk score was developed for each histopathological class using univariate and logistic regression analyses.

Results: Variables independently associated with focal class included disease duration up to diagnosis < 8 weeks, absence of red blood cell (RBC) casts by urine microscopy and eGFR > 49ml/min/1.73m^2; with crescentic class > 40 erythrocytes/hpf, identification of RBC casts in urine, ear nose and throat (ENT) involvement and eGFR < 49ml/min/1.73m^2; with mixed class age > 54 years, male gender, and absence of ENT involvement. In the presence of 2 or 3 risk factors a predictive risk score of each histopathological class was calculated: odds ratio (OR), 95% confidence intervals (CI), for focal class (³2 risk factors) 17.5 (95% CI) [4.9-62.9], 38.0 [6.8-213.7] for crescentic class (³3 risk factors), and 8.3 [1.0-67.5] (³2 risk factors) for mixed class.

Conclusions: We propose a predictive algorithm of specific histolopathological classes of ANCA-associated GN, which might provide a crude estimation of the disease activity in the glomeruli at presentation. This tool might assist the clinician in making decisions regarding the level of intensity of inductive immunosuppressive therapy at clinical diagnosis.

FR-PO411

Rituximab as a Cyclophosphimide Sparing Agent for Patients with Multi-Relapsing ANCA-Associated Small Vessel Vasculitis Sophia Lionaki,[1] George E. Fragoulis,[2] Alice Venetsanopoulou,[2] John N. Boletis,[1] Panagiotis Vlachogiannopoulos,[2] Haralampos Moutsopoulos,[2] Athanasios Tzioufas.[2] *[1]Nephrology, Laiko Hospital, Greece; [2]Pathophysiology, Univ of Athens, Greece.*

Background: To evaluate the clinical efficacy and outcomes, of patients with multi-relapsing ANCA-associated Vasculitis (AAV), who received induction therapy with rituximab for a new disease relapse.

Methods: We retrospectively studied all patients with biopsy proven AAV, who were treated with rituximab upon a new relapse. A control group consisted of patients from the era prior to the initiation of rituximab in the treatment of AAV, was selected using the following criteria; i/history of relapse, ii/organ involvement at relapse, iii/ treatment with the standard regimen. Patients and controls were matched for age, gender, and disease duration. Comparisons of disease outcomes along with the frequency and severity of adverse events were performed between groups. Rituximab was used with high dose glucocorticoids and depending on the organ involvement a short course of cyclophosphamide was added.

Results: Of 147 patients with AAV and a mean total follow up time of 78.2 months, 18 patients (12.2%) received induction treatment with rituximab for disease relapse. Time to 1st relapse from the 1st diagnosis of AAV was shorter in the rituximab group and the mean number of relapses per patient was significantly higher in this group. The mean BVAS score was similar between groups at study entry while 13/18 patients received a 3-month course of cyclophosphamide in addition to rituximab.

Characteristic	Rituximab group, N=18	Control group, N=18	p-value
Number of relapses per patient up to study entry (median) (range)	2 (1-4)	1(1-2)	0.009
Subsequent relapse, N(%)	3(11.1)	4(22.2)	1.00
Cyclophosphimide exposure post study entry (mean±sd) (grams)	24.39 (±32.5)	3.25(±3.09)	0.02
Follow up time post study entry (months)(range)	37(6-68)	53(8-228)	0.07

Conclusions: Rituximab was shown efficacious in patients with multiple relapsing AAV including cases with renal and pulmonary involvement. It allowed us to minimize the ultimate exposure to cyclophosphamide in these patients, which is crucial, as they accumulate remarkable toxicity in long-term.

FR-PO412

Differences Between Patients with Definite and Suspected ANCA-Associated Vasculitis in a Secondary Care Hospital Eline Houben,[1] Willem A. Bax,[1] Walentina A. Slieker,[2] Bastiaan Van Dam,[1] Fenneke C.P. Frerichs,[1] Gideon Verhave,[1] Erik Lars Penne.[1] *[1]Dept of Nephrology, MCA-Gemini Group, Alkmaar, Netherlands; [2]Laboratory of Clinical Chemistry, Hematology and Immunology, MCA-Gemini Group, Alkmaar, Netherlands.*

Background: ANCA-associated vasculitis (AAV) is a rare disease with a broad spectrum of symptoms. Therefore, diagnosing AAV is often challenging. In an effort to provide guidance for clinicians, we aimed to identify differences between ANCA positive patients with a definite and suspected diagnosis of AAV.

Methods: In this retrospective study, all patients that tested positive for MPO and/or PR3 ANCA between 2005 and 2015 in a secondary care hospital in the Netherlands were analyzed. Patients were divided into subgroups according to clinical diagnosis and the Birmingham Vasculitis Activity Score (BVAS). Possible predictors for AAV, such as patient characteristics, clinical symptoms and ANCA titers were identified. Patients were also screened for commonly used exclusion criteria in trials.

Results: We included 240 patients with a positive MPO and/or PR3 ANCA, of which 120 patients were clinically diagnosed with AAV (group 1); all had a BVAS ≥ 3. Of the patients without the diagnosis AAV, 50 had a BVAS ³3 (group 2) and 70 had a BVAS < 3 (group 3). In group 2, 39 patients had an alternative diagnosis, including other rheumatic diseases and infection. In a multivariable linear regression model, higher ANCA titers, higher BVAS and Ear Nose Throat (ENT) symptoms were predictive for AAV (all p<0.001). Of the patients diagnosed with AAV, 21 (18%) would have been excluded from most trials, based on a malignancy (n=13) or drug use associated with vasculitis (n=8). Notably, characteristics of these patients did not differ significantly from the other AAV patients.

	age	male%	Median PR3	MPO	BVAS	renal symptoms %	ENT symptoms %
Group 1	62±14	63	94 (45-179)	38 (18-101)	6 (4-8)	68	67
Group 2	56±21	50	20 (10-32)*	9 (6-15)*	4 (4-5)*	56	20*
Group 3	50±21	53	24 (11-51)*	9 (7-18)*	2 (0-2)*	23	7*

* p≤0.001 as compared to Group 1

Conclusions: MPO and PR3 ANCA can be positive in a variety of diseases that may mimic AAV. Higher ANCA titers, BVAS and ENT symptoms were predictive for AAV in ANCA positive patients.

FR-PO413

Rituximab and Low-Dose Cyclophosphamide Therapy for Renal ANCA-Associated Vasculitis: Long-Term Follow-Up Nicholas R. Medjeral-Thomas,[1,2] Nicholas D. Mansfield,[1] Stephen Paul McAdoo,[1,2] Anisha Tanna,[1,2] Megan Griffith,[1,2] Jeremy B. Levy,[1] Tom Cairns,[1] H. Terence Cook,[1,2] Alan D. Salama,[1] Ruth M. Tarzi,[2] Charles D. Pusey.[1,2] *[1]Imperial College Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom.*

Background: The previously reported study of rituximab (RTX) and low-dose cyclophosphamide (CYP) followed by azathioprine maintenance for ANCA-associated renal vasculitis (AAV), suggested it was efficacious in inducing remission and has an acceptable side-effect profile (N Mansfield et al 2011). We have followed the cohort for over seven years and report the regimen's efficacy and safety profile.

Methods: Long-term outcomes were retrospectively ascertained from all 23 previously treated patients.

Results: Mean time since starting the treatment regimen was 83 months; twenty-one patients started the regimen more than five years ago. All patients achieved clinical remission within six weeks, with depletion of circulating CD19-positive B cells and significant reduction in median anti-PR3/MPO ANCA titre. After 84 months follow-up, five renal and four non-renal relapses were observed and treated in five patients. Median eGFR improved from 28 ml/min (range 11-63) at presentation to 49 ml/min (range13-87) after one year and was maintained at 50 ml/min (8-90) at five years (n=21) and 46ml/min (22-76) at seven years follow-up (n=9). To date, three infections requiring hospital admission and four malignancies have been recorded.

Conclusions: This rituximab-based low-dose cyclophosphamide regimen followed by maintenance therapy provides safe and effective long-term treatment at more than five years follow-up.

FR-PO414

The Histopathologic and Clinical Determinants of the Change in GFR During the 1st year of Treatment in ANCA-Associated Vasculitis Pierre-Luc Lavoie,[1] Remi Goupil,[1] Michelle Goulet,[2] Maxime Rheaume,[2] Soumeya Brachemi,[3] Stephan Troyanov.[1] *[1]Nephrology, Hôpital du Sacré-Coeur, Univ de Montréal, Montréal, QC, Canada; [2]Internal Medicine, Hôpital du Sacré-Coeur, Univ de Montréal, Montréal, QC, Canada; [3]Nephrology, CHUM, Montréal, QC, Canada.*

Background: Identifying the predictors of the change in GFR in ANCA-associated vasculitis (AAV) is helpful to avoid prolonged immunosuppression in those where no benefits exist and to consider modifying therapy in those who should improve but fail to do so.

Methods: We retrospectively reviewed cases of AAV with a renal biopsy in 3 hospitals to determine predictors of the change in GFR ($delta_{GFR}$) during the 1st year of treatment. We considered demographics, pathology findings, treatments and complications incurred. In particular, we addressed the histopathologic classification (Berden JASN 2010) proposing focal, crescentic, mixed and sclerotic subsets.

Results: Of 120 patients with AAV, 71 had a renal biopsy and received immunosuppression. They presented at an age of 59±13 with 48% female, 49% anti-MPO+ and a GFR of 32±30 mL/min including 22 patients on dialysis. Induction consisted of cyclophosphamide (93%), rituximab (6%), plasma exchange (27%) and pulse methylprednisolone (69%) in addition to oral corticosteroids. During the 1st year, patients recovered 15±20 mL/min/1.73m^2 with 11 no longer requiring dialysis. The $delta_{GFR}$ increased up until 6 months, although it varied greatly individually. Age, hypertension, MPO positive serology, the extent of crescentic and sclerotic glomeruli, tubular atrophy and the histopathological classification were associated with a lower GFR at diagnosis. However, at one year only the histopathologic classification and the number of admissions for treatment-related complications predicted a lower $delta_{GFR}$. The focal, crescentic, mixed and sclerotic subsets experienced a 19±23, 17±15, 11±12 and -1±26 mL/min $delta_{GFR,}$, respectively (p=0.026, trend test).

Conclusions: The change in GFR during the 1st year of treatment in AAV increased 15±20 mL/min. It appeared maximal at 6 months into therapy. The histopathologic classification helped predict the $delta_{GFR}$ at 12 months, with a reduced benefit of therapy in the sclerotic subset.

FR-PO415

Analysis of Clinical Features in ANCA-Associated Vasculitis: 30 Years Single Center Experience – Relationship Between RPGN and Renal Prognosis Soko Kawashima, Shinya Kaname, Yoshinori Komagata, Yoshihiro Arimura. *First Dept, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.*

Background: The clinical features of AAV, with respect to rapidly progressive glomerulonephritis (RPGN), have been changing, but were not well examined in Japan, where MPO-ANCA-associated vasculitis (MPO-AAV) are dominant in contrast to the Western countries. Thus, we retrospectively analyzed the clinical database of the179 patients with AAV who were admitted to our hospital for the last 30 years.

Methods: At the onset, all patients fulfilled the Chapel Hill Consensus Conference (CHCC) classification criteria for MPA, GPA and EGPA. We divided the AAV patients into the 4 groups based on the presence or the absence of RPGN and hemodialysis, and compared the clinical features and renal prognosis. Among 179 AAV patients, 166 cases (92.7 %) were MPO-ANCA positive and 14 cases (7.8%) were PR3-ANCA positive.

Results: RPGN was observed in 100 (55.9%) of the 179 patients, including 49 cases of maintenance hemodialysis group (A), 2 cases of temporary dialysis group (B) and 49 cases of non-dialysis group (C), in addition to 79 cases without RPGN and dialysis (D). Significant differences were observed in BVAS, CRP, eGFR and serum Cr concentration. There were no differences for treatment choice, rate of kidney biopsy and frequency of relapses among the groups. Comparison among the different periods for every 10 years show the tendency of an increase in age of onset and the downward trend of serum Cr concentration, rate of RPGN and maintenance hemodialysis, BVAS scores, and frequency of relapses and mortality.

Conclusions: These results have clearly shown the changing features of AAV in Japan, with an earlier detection and the improvement of renal and patient survival during the periods.

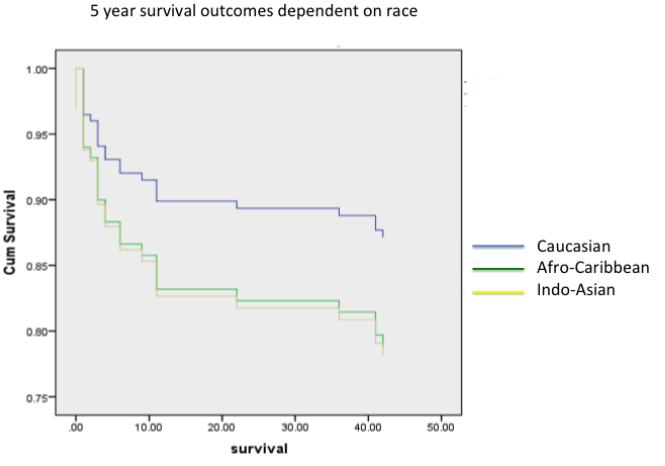
FR-PO416

The Effect of Race on 5-Year Survival Outcomes in ANCA-Associated Renal Vasculitis Luxme Nadarajah, Vasantha M. Muthuppalaniappan, Ravindra Rajakariar. *Nephrology, Barts and The London NHS Trust, United Kingdom.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis is a multi-systemic autoimmune disease characterized by inflammation of microscopic vessels. Renal involvement occurs in 70% of patients, with 1 year mortality rates exceeding 15%. With a prevalence of two cases per 100,000 populations there is a significant preponderance to Caucasians (C). Little is known about the outcomes in patients from Indo-Asian (IA) and Afro-Caribbean (AC) race despite an increasing number of cases seen with the disease.

Methods: We performed a single center, retrospective study, observing 5-year survival outcomes and relapse rates between C, IA and AC in ANCA-associated renal vasculitis. Electronic case notes over a 10-year period (2004-2014) were used collect data to include age at time of diagnosis, Birmingham vasculitis activity score (BVAS) at presentation, race, presence of diabetes and renal function. 5-year survival outcomes were analyzed using a cox proportional hazard model.

Results: In total 121 patients were included in the study, there were 84 (70%) C's, 31 (25%) IA's and 6 (5%) were of AC background. Median age was 66 years, 56% were men, 20% were diabetic and average BVAS score at presentation was 5. One-year relapse rates were low with 8 (6%) relapses seen. No significant difference in 5-year survival outcome was found between the races. Age at presentation significantly affected survival outcomes (p=0.007).



Conclusions: We conclude that survival outcomes for IA and AC are not worse compared to those of C origin. Age remains to be a significant predictor in determining mortality outcomes. This study provides valuable clinical information in an area that has not been well studied.

FR-PO417

Possibility of Increasing Prevalence of Otitis Media with ANCA Associated Vasculitis in Japan Takeshi Nakatsue,[1] Yukiko Nozawa,[1] Hiroe Sato,[1] Yoko Wada,[1] Takeshi Kuroda,[2] Masaaki Nakano,[3] Ichiei Narita.[1] *[1]Div of Clinical Nephrology and Rheumatology, Graduate School of Medical and Dental Sciences, Niigata Univ, Niigata, Japan; [2]Health Administration Center, Niigata Univ, Niigata, Japan; [3]Dept of Medical Technology, School of Health Sciences, Faculty of Medicine, Niigata Univ, Niigata, Japan.*

Background: A new disease concept, otitis media with ANCA associated vasculitis (AAV), has been advocated.

Methods: One hundred and fifty seven patients (74 males and 83 females) with AAV (81 microscopic polyangiitis, 54 granulomatosis with polyangiitis (GPA), and 22 eosinophilic GPA) were admitted to Niigata University Hospital from 1989 through 2014. Twenty seven patients (17%, 13 males and 14 females) with otitis media were recruited. Their clinical features and laboratory data were analyzed.

Results: Fifteen patients were diagnosed as having definite GPA. Five were probable GPA. Lung or kidney lesions were not detected in other seven patients (Ears (E) only group). The initial symptoms in 22 patients (81 %) were ears' one, such as impaired hearing (91

%), congested feeling (32 %), otalgia (14 %), or tinnitus (14 %). No evidence of vasculitis was proved in E only group. MPO- and PR3-ANCA were positive in 19 (70 %) and six cases (22 %), respectively. PR3-ANCA was observed only in definite GPA. MPO-ANCA titer in definite or probable GPA and in E only group were 103 ± 73.4 U/ml and 41.8 ± 26.4 U/ml, respectively ($p<0.05$). From 1989 through 2009, 10 cases of otitis media with AAV (OMAAV) (0.48 /year) out of 84 cases of AAV (4.0 /year) were observed, whereas 17 cases of OMAAV (3.4 /year) out of 73 cases of AAV (14.6 /year) were observed from 2010 through 2014 ($p<0.05$). All of E only group was seen in this period. Hypertrophic pachymeningitis was seen in seven cases (26 %). Otitis media was involved in bilateral ears in 19 cases (70 %). Lung and kidney lesions were in 20 and 11 cases, respectively. Necrotizing crescentic glomerulonephritis were observed in six cases. Some renal biopsies were avoided because of patients' impaired hearing.

Conclusions: OMAAV is increasing. Chest X ray, urinary test, and measuring ANCA should be considered in refractory otitis media.

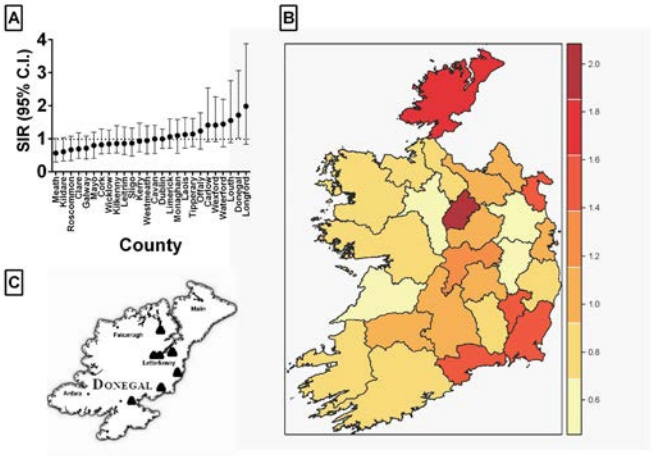
FR-PO418

Temporal and Spatial Clustering of Anti-Glomerular Basement Membrane Disease Mark N. Canney,[1,2] Paul O'Hara,[1] Caitriona M. McEvoy,[1] Aileen C. Niland,[1] Mark Alan Little.[2] *[1]Irish Anti-GBM Study Group; [2]Trinity Health Kidney Centre, Trinity College Dublin.*

Background: An environmental trigger has been proposed as an inciting factor in anti-glomerular basement membrane (anti-GBM) disease. We aimed to define country-wide incidence of anti-GBM disease, investigate clustering of cases in time and space and to assess the impact of spatial variability in incidence on outcomes.

Methods: National multicentre observational study of anti-GBM disease cases diagnosed in Ireland 1.6.2003-31.5.2014. We ascertained cases by screening immunology laboratories for instances of positive anti-GBM antibody and the national renal histopathology registry for biopsy-proven cases. We defined the population at risk using census figures. A variable-window scan statistic was used to detect temporal clustering. A Bayesian autoregressive spatial model was used to provide standardised incidence ratio (SIR) estimates for each county. Patient and renal survival were assessed using Kaplan-Meier and log-rank test.

Results: Seventy-nine cases were included. National incidence was 1.64 (95% CI 0.82-3.35) pmp/year. A temporal cluster was identified (n=10) in a 3 month period in early 2013; 6 (60%) were resident in the southeast. Spatial analysis revealed wide regional variation in SIR (fig 1A) and a cluster (B,C) in the northwest (n=7, SIR 1.71, 95% CI 1.02-3.06).



However, being in a cluster or distance from diagnosis site to treating center did not significantly impact on patient (HR 1.8, 95% CI 0.9-3.8) or renal survival (HR 0.7, 95% CI 0.4-1.1).

Conclusions: Country-wide incidence of anti-GBM disease is higher than reported by single centre studies. We detected clustering of cases in time and space supporting the hypothesis of an environmental trigger. Wide regional variation in incidence highlights the need for country-wide epidemiological studies of anti-GBM disease to further our understanding of its aetiology.

FR-PO419

Venous Thromboembolism in ANCA Vasculitis Is Associated with Elevated Microparticle Tissue Factor Activity Elizabeth J. Brant, Carmen E. Mendoza, Yichun Hu, Susan L. Hogan, Ronald J. Falk, Patrick H. Nachman, Vimal K. Derebail, Donna O. Bunch. *UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Venous thromboembolism (VTE) is a severe complication of ANCA vasculitis (AAV). Mechanisms of VTE are not known, but tissue factor (TF)-bearing microparticles (MPs) from activated or apoptotic cells may play a role. We hypothesized that elevated microparticle tissue factor activity (MPTFa) is associated with VTE in AAV.

Methods: Patients without VTE (VTE^{neg}) were enrolled prospectively during active disease. Patients with VTE (VTE^{pos}) were included whether active or in remission at the time of VTE. Longitudinal platelet-free plasma (PFP) samples from 28 patients and 16 healthy controls (HC) were assayed for MPTFa. All patients had ³3 samples spanning ³12 months. MPs isolated by centrifugation were incubated with Factor VIIa and Factor X. Absorbance was measured after addition of Factor Xa chromogenic substrate. Recombinant relipidated human TF was used as a standard. Values were expressed as a percent of MPTFa from a positive control (PFP from LPS-stimulated HC blood). Fisher's exact tests and Wilcoxon tests were used to compare categorical and continuous variables, respectively.

Results: Demographics were similar among patients and HC. VTE^{pos} and VTE^{neg} patients did not differ in ANCA serotype or titer, BVAS, D-dimer, other laboratory data, or organ involvement. VTE^{pos} patients had significantly higher peak MPTFa than VTE^{neg} patients (median 10.5 (IQR 9.7, 31.3) vs 2.8 (IQR 0.8, 5.2), $p<0.0001$) and tended to have recurrently elevated levels. MPTFa of VTE^{neg} patients was similar to HC (median 2.0 (IQR 1.1, 3.3), $p=0.4$). All VTE^{pos} patients had peak MPTFa above normal (mean + 2SD of HC = 6.5) versus 2/20 VTE^{neg} patients ($p<0.0001$).

Conclusions: Patients with AAV who develop VTE have a notable propensity for increased MPTFa at times both near and remote from VTE. Conversely, those without VTE rarely exhibit MPTFa significantly higher than healthy controls during their disease course. Further study is needed to determine if elevated MPTFa can identify AAV patients at high risk for VTE and whether MPTFa contributes to thrombogenesis.

FR-PO420

CD80 and Angiopoietin-Like 4 in Glomerulopathies Gabriel M. Cara-Fuentes,[1] Alfonso Segarra,[2] Eduardo H. Garin.[1] *[1]Pediatrics- Div of Nephrology, Univ of Florida, Gainesville, FL; [2]Nephrology, Vall D'Hebron, Barcelona, Catalonia, Spain.*

Background: Proteinuria in MCD is thought to be due to an increased CD80 podocyte expression. Recently, podocyte angiopoietin-like 4 (Angptl4), has been suggested to induce proteinuria in MCD. **Objective:** To determine the pattern of CD80 and Angptl4 in MCD and other glomerulopathies.

Methods: 34, 30 and 32 patients with biopsy-proven MCD, FSGS and MN respectively, were included. Urinary and serum CD80 and Angptl4 were measured by Elisa. Differentiated human podocytes were incubated for 6 h with 15% of serum from MCD patients in relapse or in remission. Podocyte expression of CD80 and Angptl4 were measured by Western-Blot analysis. Urinary Angptl4 pI was measured by 2D electrophoresis Statistical analysis:Mann-Whitney *U* test, Wilcoxon matched-pairs signed rank test for comparison of paired groups, and Spearman correlation.

Results: Urinary CD80 was increased in MCD patients during relapse, but not in patients with FSGS or MN, or normal controls. Serum CD80 was lower in patients with glomerulopathies during relapse compared to normal controls. Urinary Angptl4 was increased in patients with glomerulopathies compared to normal controls, whereas serum Angptl4 was higher in normal controls compared to patients with glomerulopathies. Both urinary CD80 and Angptl4 correlated with proteinuria in MCD, FSGS and MN. Podocytes exposed to sera from MCD patients in relapse showed a significant increase in CD80 expression but not Angptl4 when compared to MCD patients in remission. Urinary Angptl4 pI was 5.4.

Conclusions: 1) Decreased serum CD80 and Angptl4 in nephrotic syndrome is likely due to increased urinary losses. 2) Increased urinary CD80 was only observed in MCD patients in relapse while increased urinary Angptl4 was seen in all the glomerulopathies. 3) Podocyte CD80 but not Angptl4 expression was increased by serum from MCD patients in relapse. 4) Urine Angptl4 in MCD has a pI of 5.4, suggesting no role on Glomerular Basement Membrane charge. 5) While CD80 seems to play a role in proteinuria in MCD, Angptl4 detected in urine in MCD and other glomerulopathies is likely the result of an increased glomerular permeability.

FR-PO421

ApoL1 Polymorphism Determines HIV Boarding in Human Podocytes Pravin C. Singhal,[1] Xiqian Lan,[1] Ashwani Malhotra,[1] Karl Leon Skorecki,[2] Joanna Mikulak.[3] *[1]Dept of Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; [2]Medicine, Rambam Health Care Campus, Haifa, Israel; [3]Clinical and Experimental Immunology, Humanitas Clinical and Research Center, Milan, Italy.*

Background: Patients of African ancestry with untreated HIV infection, carrying the G1 or G2 kidney disease risk variants (Vs) at the *APOL1* gene are at a >10-fold greater risk for developing HIV-associated nephropathy (HIVAN) compared to those without these risk variants. Although podocytopathy in HIVAN has been attributed to the direct effect of HIV infection, the mechanistic contribution to kidney injury of the *APOL1* allelic state remains to be elucidated.

Methods: We evaluated the priming effect of IL-1β on human podocyte (HP) APOL1 expression. To evaluate the effect of IL-1ß on HIV-1 processing in podocytes, HPs were pre-stimulated with human recombinant IL-1ß for 6h and then incubated with HIV-1 followed by analysis for the HIV-1 strong stop DNA by qPCR analysis. HPs treated under similar conditions were evaluated for Dc-sign (a receptor known to contribute for podocyte HIV entry) expression. To determine the effect of over expression of APOL1 (G0) and APOL1 variants (G1/G2) HPs were either transfected with APOL1G0/G1/G2 plasmids, or HPs were pre-stimulated with 10 ng/mL of IFN-γ and then incubated with HIV-1 and analyzed for HIV-1 strong stop DNA concentration at various time points and also measured for their lysosomal bioactivity.

Results: APOL1 expression increased after incubation of podocytes with the HIV. In turn, APOL1 expression was further enhanced in response to augmented entry of virus consequent to enhanced expression of Dc-sign and IL-1 β treatment, consistent with viral load dependency. Podocytes over-expressing the non-risk APOL1 gene (G0), either through

pre-treatment with IFN-γ or through transfection with the specific APOL1-expressing plasmid displayed diminished HIV accumulation. In contrast, comparably increased expression of the APOL1 variants was not only permissive for HIV entry but also facilitated HIV accumulation through down regulation of lysosomal bioactivity.

Conclusions: These findings indicate that ApoL1 polymorphism may determine HIV boarding in human podocytes.

FR-PO422

Podocyte Depletion in Alport Syndrome Complex Larysa T. Wickman, Jeffrey B. Hodgin, Su Qing Wang, Farsad Afshinnia, David B. Kershaw, Roger C. Wiggins. *Univ of Michigan.*

Background: Increasing evidence suggests that podocytes may play a role in Alport Syndrome Complex (ASC) progression of renal disease. We previously reported that podocyte detachment rate measured in urine is increased in ASC, suggesting that podocyte depletion could play a role in causing progressive loss of kidney function. This result therefore raised the question as to whether progression in ASC could be due to progressive podocyte depletion from glomeruli.

Methods: To address this question we measured podocyte nuclear number, density and cell area (Glepp1 positive) density in the same 3um thick formalin-fixed paraffin-embedded histologic section. Twenty six kidney biopsies from 21 patients were collectively designated as ASC including both classic Alport Syndrome (with thin and thick GBM segments and lamellated lamina densa [n=20]) and Thin GBM [n=6]. Twenty protocol kidney biopsies from deceased kidney transplant donors were used as age-matched controls.

Results: When compared to controls, podocyte number per glomerulus, % podocyte depletion, nuclear density and cell area density were all decreased in the ASC cohort ($P<0.01$). The mean podocyte volume (MPV) was correspondingly larger for ASC than control ($P<0.05$) representing podocyte hypertrophy to compensate for reduced podocyte number and density. Podocyte depletion was present in ASC biopsies prior to detectable histologic abnormalities. No abnormality was detected by light microscopy at <30% podocyte depletion, minor pathologic changes (mesangial expansion and adhesions to Bowman's capsule) were present at 30-50% podocyte depletion, and FSGS was progressively present above 50% podocyte depletion. Estimated GFR did not change measurably until >70% podocyte depletion. Low level proteinuria was an early event at about 25% podocyte depletion and increased in proportion to podocyte depletion.

Conclusions: These data support the concept that progressive podocyte depletion occurs from an early stage in ASC leading to FSGS-like pathologic changes and eventually to End Stage Kidney Disease. Early intervention to reduce podocyte depletion is projected to prolong kidney survival in ASC.

FR-PO423

Actinin-4, Synaptopodin, Nephrin, and Neph-1 Expression in Protienuric Patients Ashwani Kumar,[1] Ritambhra Nada,[1] Charan Singh Rayat,[1] Krishan L. Gupta.[2] *[1]Dept of Histopathology, Post Graduate Inst of Medical and Research, Chandigarh, India; [2]Dept of Nephrology, Post Graduate Inst of Medical and Research, Chandigarh, India.*

Background: Podocytes have an important role in glomerular filtration barrier. Primary podocytopathies and secondary podocyte injuries in presence of immune deposits at different locations results in proteinuria. We compared expression of podocyte structural proteins; alpha actinin-4 (αAct-4), synaptopodin (Syn), and slit diaphragm proteins; nephrin (Nep), and neph-1 by immunofluorescence (IF) in minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous glomerulonephritis (MGN), and IgA nephropathy (IgAN).

Methods: Two hundred cases (n-50 each) along with controls were stained with FITC tagged αAct-4, Nep, Syn, and Neph-1 antibodies. Immunofluorescence was graded as mild, moderate, and intense. Immunogold staining with αAct-4, and Syn antibodies was done to see localization electronmicroscopically (EM).

Results: The αAct-4 showed mild to moderate intensity (40% & 60%) in controls and most of the cases in all proteinuric groups. Up-regulation was noted in 52% cases of MGN and only 14-19% of other groups. Loss of αAct-4 was seen in about 15-25% in all groups except MGN where it was rare. Syn showed mostly mild staining (70%) in controls. Marked up-regulation (61%) was seen in the majority of MGN cases whereas moderate intensity was seen in other groups (MCD>IgAN>FSGS). Loss of staining was less but equally present in all groups. Nep showed mild intensity in controls; however moderate to intense staining was seen in MGN (46% & 14%), whereas loss of staining was noted in all other groups (FSGS-54%, MCD-43, IgAN-59%). Neph-1 also showed mild staining in controls. However, up-regulation was seen in only MGN (47%). Similar to Nep, complete loss of Neph-1 was seen in FSGS-74%, MCD-53%, and IgAN-54%. These differences in staining of MGN were statistically significant when compared with controls and with other groups. EM showed αAct-4 and Syn in podocyte body and processes.

Conclusions: Structural proteins and slit diaphragm proteins are up-regulated in MGN whereas the variable degree of loss is commonly seen in FSGS, MCD, and IgAN.

FR-PO424

Use of Spot Urine Protein Creatinine Ratio to Predict Proteinuria in Nephrotic Syndrome in NEPTUNE Marie C. Hogan,[1] Jonathan P. Troost,[2] Peter J. Nelson,[3] Heather N. Reich,[4] Sharon G. Adler,[5] Daniel C. Cattran,[4] Gerald B. Appel,[6] Debbie S. Gipson,[2] Wenjun Ju,[2] Matthias Kretzler,[2] John C. Lieske.[1] *[1]Mayo; [2]UMich; [3]UWash; [4]UT; [5]UCLA; [6]ColumbiaU.*

Background: Random urine protein creatinine ratio (UPC) is used to estimate 24 hr urine protein excretion (24P) yet little data are available wrt sensitivity & specificity, especially in pts with glomerular proteinuria.

Methods: The Nephrotic Syndrome Study Network (NEPTUNE) studies newly diagnosed patients with MCD, FSGS, & MN. Total protein, alb & creat are measured in random & 24 hr urine collections at a central biobank at postbiopsy baseline & subsequent visits within 2 yrs of dx.

Results: Of 603 participants, 302 have same day spot & 24 hr ur samples with a total of 827 samples across all visits eligible for this analysis. Urine protein excretion (g; median; 25, 75%) was higher in adults (1.0; 0.3, 2.3) than peds (0.2; 0, 0.7). Spot UPC correlated better with 24 hr UPC than 24P in both adults (r=0.79 vs 0.60) & peds (r=0.84 vs 0.67). Using these data we derived equations to predict 24P from spot UPCs: for adults 24P == [10]^((0.88*(log_10 [Spot UP:C))]) & for peds was 24P =[10]^((1.06*(log_10 [Spot UP:C))]). The efficiency (AUC) of spot UPC to accurately predict 24P values above thresholds of 0.5g, 1.0g, 2.0g, 3.0g, 6.0g and 10.g ranged from 0.83-0.97 in adults & peds. In subgroup analysis the correlation between log-transformed UPC and log-transformed 24P was similar in all age ranges & diseases, but stronger in obese vs. normal wt subjects ($b_{Normal\ wt}$=0.78 (0.69, 0.88); b_{Overwt}=0.85 (0.78, 0.93); b_{Obese}=0.93 (0.85, 1.0) p=0.03).

Conclusions: Among MCD, FSGS, & MN pts UPC correlates only moderately with 24P. 24P is best derived from spot UPC using a non-linear estimating equation. Wt influences reliability of spot UPC. Our data also suggest UPC can be used with caution to identify those pts with 24P above clinically relevant cut points. As 24P is susceptible to collection errors & implications of threshold values may be dependent on patient size, additional studies to evaluate spot UPC vs 24P and clinical outcomes are warranted.

Rituximab in Steroid Dependent and Calcineurin Inhibitor (CNI) Dependent/Intolerant Adult Idiopathic Minimal Change Disease and Focal Segmental Glomerulosclerosis Harbir Singh Kohli, Raja Ramachandran, Vivekanand Jha, Krishan L. Gupta. *Nephrology, PGIMER, Chandigarh, UT, India.*

Background: Steroid dependent (SD) nephrotic syndrome (NS) is managed with CNIs but the long-term results are limited by CNI nephrotoxicity and dependence. This prospective study was done to evaluate the effect of rituximab in those SD-NS who were either CNI dependent or had CNI induced nephrotoxicity.

Methods: This prospective study was undertaken in patients of SD MCD/FSGS patients were given initially CNI (tacrolimus). Of these, who were either tacrolimus (TAC) dependent (relapse NS on tapering or stopping after 1 year at least) or had TAC induced nephrotoxocity (rise in serum creatinine >2 times the baseline) were enrolled for rituximab administration during Oct 2013 to Oct 2014. Patient with at least 6 months follow-up were analysed. After achieving remission with oral prednisolone the steroids were tapered to stop and single dose of Rituximab (375 mg/m^2) was administered. CD-19 count was performed at Day 2 and at 3 months. Outcome studied was remission complete or partial at the end of 6 months. Complete remission (CR): 24-hour urine protein < 500 mg/day with normal serum albumin (³3.5 gm/dl). Partial remission (PR): 24 hour urine protein ≥500 mg/day but <2 gm/day or <50% of baseline with normal serum albumin (³3.5 gm/dl).

Results: A total of 12 cases, 10 Tac dependent (duration of TAC-35 ±12.6 months) and 2 with nephrotoxicity were studied. Basic disease was MCD in 4 (33.3%) and FSGS In 8 (66.7%). Mean age was 21.8± 8.4 yrs. Mean proteinuria, serum albumin and serum creatinine prior to enrollment in the study were 3.24±1.57 gm/day, 2.52±0.78 gm/dl and 0.79±0.15 mg/dl respectively. All achieved target CD-19 (<1%) with single infusion and 4 (25%) cases had risen in their CD 19 at 3 months and were given second dose. At 6 months, CR and PR was achieved in 9(75%) and 1(8.3%) respectively. There were 2 non-responders (16.6%). Of the 10 responders,3 have completed 1 yr of follw-up and are in remission. Adverse event (pneumonia) was noted in 1 patient (8.3%).

Conclusions: Rituximab appears to be a promising agent in the management of adult CNI dependent or intolerant NS due to MCD/FSGS with minimal short-term adverse events.

FR-PO426

Treatment and Outcomes in Minimal Change Disease: Experience of a Single UK Centre Anthony Fenton, Stuart W. Smith, Peter Hewins. *Dept of Renal Medicine, Univ Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Minimal change disease (MCD) accounts for 10-25% of nephrotic syndrome in adults. We retrospectively reviewed the treatment and outcomes of MCD patients in our centre.

Methods: We identified adults who had undergone renal biopsy between June 1996 and March 2012 which was reported as being consistent with MCD, and who had at least 12 months of follow-up. Electronic hospital records were used for data collection.

Results: There were 78 cases, with median follow-up of 72 months. Baseline and treatment data are shown in the table (averages are mean, or median where distribution is skewed). 27% had a history of nephrotic syndrome in childhood. All but one patient (who entered remission spontaneously) were treated with prednisolone, and 97% achieved complete remission at a median time of 33 days (6-309), although 12% needed a second-line agent to do so. Mean number of relapses during the first 24 months was 1.0. 68% experienced at least one relapse, and 45% patients required second-line agents at some point. Regarding complications: 12% developed thromboembolic disease, 14% had an admission-requiring infection, and 41% had at least one episode of AKI. Mean follow-up creatinine was 91 mmol/L, but significantly higher in those who had had AKI (104 vs 85 p=0.04) and those who had received an ACEi (99 vs 78 p=0.01). Of 16 patients who underwent subsequent biopsy (all of whom had received a CNI), 8 showed evidence of CNI damage, and 5 were consistent with FSGS. Diabetes mellitus developed in 12% cases, and 8% patients died during follow-up.

Conclusions: Almost all treated adult MCD patients enter remission, although second-line agents are frequently required. Despite therapy, complications remain common, including AKI which is associated with residual reduced excretory function.

Predictors for Relapse in Adult Minimal Change Disease Hajeong Lee, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Chun Soo Lim. *Internal Medicine, Seoul National Univ Hospital.*

Background: Minimal change disease (MCD) is well-known benign primary glomerulonephritis in adults because of their distinct rare renal progression to end-stage. However, their relapse-associated morbidity has been underestimated. In this study, we aimed to explore the predictors of relapse in adult MCD patients.

Methods: We reviewed clinical and pathologic characteristics of adult primary MCD patients from Seoul National University Hospital from 1979 to 2013. Patients who were presented by nephrotic syndrome and followed up more than 12 months were included. Patients suspicious for secondary MCD were excluded. Initial treatment regimens, their response, and complication were also reviewed. The number of relapse were classified as follows, no relapse, 1-2 relapses (relapse group 1), and ≥ 3 relapses (relapse group 2).

Results: A total of 195 patients were included in the final analysis. Among them, median age at the time of diagnosis was 38 (23–53) years and 113 (57.9%) were men. During median follow up of 81 (44–153) months, more than 90% of patients reached to remission after initial treatment. However, only 64 (32.8%) patients did not experience any relapse. Remaining 131 patients, 69 (35.4%) relapsed once or twice and 62 (31.8%) relapsed more than three-times. The younger, the more relapse was found. In addition, severity of nephrotic syndrome including was proportional to the relapse. Interestingly, proportion of mesangial proliferation was higher in no-relapse group compared with relapse group 1 and 2 (P = 0.033). Initial treatment regimen did not affect relapse, however, patients who received shorter treatment duration tended to relapse more. Considering complications, relapse group 2 showed significantly higher proportion of thromboembolic event than other two groups. Multivariate analyses found that younger age, lower serum albumin, mesangial proliferation and treatment duration remained as independent risk factor for relapse.

Conclusions: We proved that patients with younger age, severe nephrotic syndrome, lower mesangial proliferation and shorter treatment duration were prone to relapses. Moreover, relapse is morbid due to higher thromboembolic events in adult MCD patients.

FR-PO428

Rituximab in Relapsing Minimal Change Glomerulonephritis: Clinical Outcomes and Financial Analysis Kevin William Loudon, Clare Morlidge, Suresh Mathavakkannan, Ken Farrington, Barbara Thompson, Paul Warwicker. *Dept of Renal Medicine, Lister Hospital, United Kingdom.*

Background: Minimal change disease (MCD) accounts for 10-15% of adult nephrotic syndrome, with frequent relapses or steroid-dependency occurring in 25-30%. Glucocorticoids and calcineurin inhibitors are the mainstay of treatment, but can be associated with significant toxicity. Rituximab holds potential to induce long term remission in these patients, but in the United Kingdom is currently not funded based on perceived excessive cost.

Methods: Nine patients with frequently relapsing MCD (histologically confirmed) were given total dose Rituximab 1g – 2.4g divided into two - four doses from 2012 - 2014. Time from diagnosis to first Rituximab dose was 140 months (10 – 336). Cost effectiveness of Rituximab was assessed based on comparing annual relapse rates; inpatient/outpatient attendances and immunosuppressant medication in the two years prior, and one year post Rituximab. Data was obtained retrospectively using hospital finance records, NHS standard tariff and the British National Formulary (2015) respectively.

Results: In all nine patients Rituximab induced complete remission. All steroid-sparing agents were discontinued. Four patients remain on low dose prednisolone (less than 4mg). Mean follow-up was 15 months (6 – 30) with only one relapse at 19 months. Annual relapse rates fell from 1.83/year (0.5 – 6.0) to 0.12/year (0-0.57). Inpatient days fell from a mean of 4.2 days/year (0-39.6) to 1.7 days/year (0-4.5). Outpatient consultations fell from 12.5/year (5-26.4) to 7.3/year (4.5-25). Mean annualised pre-Rituximab costs were £6172 and post Rituximab, £5046, in 6/9 patients with sufficient length of follow up for comparison. No major complications were noted following treatment.

Conclusions: In patients with relapsing MCD, Rituximab proved to be cost effective and well tolerated. Burden of medication with attendant side effects, as well as inpatient and outpatient attendance were significantly reduced. Annualised costings showed a modest saving post Rituximab. Further randomised studies are required to confirm and extend these findings.

FR-PO429

Long-Term Outcomes of Nephrotic Syndrome, from Childhood into Adulthood Rebecca C. Hjorten, Frederick J. Kaskel, Kimberly J. Reidy. *Pediatrics, Div of Nephrology, Albert Einstein College of Medicine, Children's Hospital at Montefiore, Bronx, NY.*

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is known to have several long term sequelae including chronic and End Stage Kidney Disease (CKD and ESKD). However there are few studies on the long-term outcomes of steroid sensitive nephrotic syndrome. Presented here is a single center, retrospective case series from an urban, ethnically diverse population in the Bronx.

Methods: We utilized a medical record data mining tool to identify patients by ICD-9 code (1) with a diagnosis of nephrotic syndrome prior to age 18 (2) with a documented albumin <3.5 g/dL or random urine protein > 1 g/dL and (3) with at least one hospital encounter after age 18. Patients with a history of renal biopsy or who received immunosuppressant medication other than steroids were termed complicated nephrotic syndrome (CNS). All others were termed simple nephrotic syndrome (SNS). Patients with a diagnosis of asthma prior to age 18 with at least one hospital encounter after the age of 18 were used as controls. Each cohort was evaluated for diagnosis of hypertension, osteoporosis, cataracts, infertility and malignancy. Their last height, weight and creatinine were used to evaluate their height and weight percentile, BMI and estimated GFR by the MDRD equation.

Results: All three groups – SNS (n=173), CNS (n=169) and control (n=18225) had similar age at diagnosis, length of follow-up. Both the SNS and CNS groups had a greater proportion of short stature, cataracts, infertility and malignancy (Chi square statistic $p < 0.05$) [table 1]. In addition they had a greater percentage of patients with CKD by eGFR which is most notable at CKD stages 4 and 5 (Chi square statistic $p < 0.05$).

Conclusions: Our results show that even patients with uncomplicated nephrotic syndrome are at risk for significant outcomes, including chronic kidney disease. Further study is needed, however it implies that all patients with a diagnosis of nephrotic syndrome will need to be counseled regarding the risks associated with their diagnosis and should have long term monitoring for these outcomes, including worsening renal function, hypertension and malignancy.

FR-PO430

Apolipoprotein CI Levels Are Associated with the Urinary Protein/Urinary Creatinine Levels in Pediatric Idiopathic Steroid-Sensitive Nephrotic Syndrome Jun Odaka, Takahiro Kanai, Takane Ito, Jun Aoyagi, Takanori Yamagata. *Pediatrics, Jichi Medical Univ, Shimotsuke, Tochigi, Japan.*

Background: Various humoral factors have been proposed as causal agents of idiopathic steroid-sensitive nephrotic syndrome (ISSNS). In the present study, we analyzed serum proteins using mass spectrometry (MS) in a search for proteins that might be related to ISSNS pathophysiology.

Methods: We collected serial serum samples from 33 children with ISSNS. The serum samples were collected in each phase as follows: Phase A1 [the acute phase prior to steroid treatment (STx)], Phase A2 [remission with STx], and Phase A3 [remission without any medication]. We also included two control groups comprised of children with normal urinalysis (Group B) and children with a nephrotic syndrome other than ISSNS (Group C). The urinary protein/urinary creatinine (UP/UCr) ratios were not statistically different between Phase A1 and Group C. We used surface-enhanced laser desorption/ionization time of flight MS to analyzed samples.

Results: A total of 207 peptide ion peaks were detected in the range of m/z 2000–10000. Four peptide ions (m/z 6444, 6626, 8695, and 8915) were significant elevated during Phase A1 compared with Phase A2, Phase A3, and Group C. The intensities of m/z 6626, 8695, and 8915 were significantly correlated with UP/UCr levels. The m/z 6626 was identified as apolipoprotein CI (Apo CI).

Conclusions: Apo CI was detected as a protein associated with the UP/UCr levels in pediatric ISSNS. Our findings provide new insight into elucidating the pathophysiology of ISSNS.

Ofatumumab in Two Nephrotic Syndrome Children Marina Vivarelli,[1] Manuela Colucci,[1] Alice Bonanni,[2] Francesco Emma,[1] Gian Marco Ghiggeri.[2] *[1]Nephrology and Dialysis, IRCCS Bambino Gesu' Pediatric Hospital, Rome, Italy; [2]Nephrology and Dialysis, Gaslini Pediatric Hospital, Genova, Italy.*

Background: Rituximab (RTX), an anti-CD20 monoclonal antibody, is an effective treatment in patients with frequently-relapsing or steroid-dependent nephrotic syndrome (Ravani, JASN 2015). However, some patients develop adverse reactions. We describe the use of a humanized anti-CD20 monoclonal antibody, ofatumumab (OFA), as a viable alternative.

Methods: Patient 1 is a 3-yr-old boy who presented at 18 months with NS initially resistant to treatment with oral prednisone. He was then treated with 3 iv boluses of methylprednisolone followed by cyclosporinA, with remission. Upon steroid discontinuation, NS relapsed. Prednisone was restarted and a single dose of RTX was planned, but was never completed as at start of infusion a severe allergic reaction (urticaria, dyspnea) occurred. Patient 2 is a 14-yr-old boy with SDNS since the age of 2 years treated with oral prednisone, cyclosporinA and micophenolate mofetil (MMF), with the development of severe obesity. A first infusion of RTX at age 12 was well tolerated and allowed prednisone discontinuation for over 2 years. Then a prolonged (>30 days) relapse occurred under treatment with oral prednisone, MMF and cyclosporinA. Therefore, a second RTX infusion was attempted, but the child presented severe dyspnea and it was interrupted. The use of OFA at 1,5 g/1.73 m2, described in steroid-resistant NS children (Basu, NEJM 2014), was attempted. In patient 2 OFA was preceded by three boluses of iv methylprednisolone to induce remission.

Results: In pt 1, OFA infusion was uneventful. In pt 2, a mild allergic reaction was observed and treated. Remission was maintained during the follow-up period (9 months for pt 1, 5 months for pt 2), despite the interruption of prednisone treatment in both patients, and in pt 1 of cyclosporinA, while in pt 2 of MMF with ongoing cyclosporinA at last follow-up. After OFA infusion, CD19+ B cells reappeared at 7 months in pt 1, while remained depleted (0%) at 5 months in pt 2.

Conclusions: OFA could be a therapeutic option in managing severe forms of drug-resistant nephrotic syndrome in patients who have developed intolerance to RTX.

Population-Based Identification of Children with Primary Nephrotic Syndrome: Kaiser Permanente Nephrotic Syndrome Study Alan S. Go,[1] Dongjie Fan,[1] Thida Tan,[1] Janet M. Wojcicki,[2] Jingrong Yang,[1] Juan Daniel Ordonez,[1] Glenn Matthew Chertow,[3] Sijie Zheng,[1] David Law.[1] *[1]Kaiser Permanente Northern California; [2]Univ of California, San Francisco; [3]Stanford Univ.*

Background: Few population-based data exist about children with primary nephrotic syndrome (NS) in the US. We identified a cohort of children with primary NS in a large integrated healthcare system.

Methods: Kaiser Permanente Northern California cares for >750,000 children. We identified members age<18 yrs between 1996-2012 who had nephrotic range proteinuria (UACR>3500 mcg/mg, PCR>3.5 mg/mg, 24-hr protein>3500 mg, dipstick>300 mg/dL) or diagnosed NS (ICD-9 581.x) in electronic records and lab databases. Nephrologists reviewed records for clinical presentation, lab and biopsy results to confirm primary NS.

Results: We identified 179 children with NS due to minimal change disease (72%), focal segmental glomerulosclerosis (23%) or membranous nephropathy (5%); incidence was 1.47 per 100,000 (95% CI:1.27-1.70). Biopsies were available in 40% of cases. Baseline features at diagnosis are shown by cause of NS:

	Overall (N=179)	Minimal Change Disease (N=129)	FSGS (N=42)	Membranous Nephropathy (n=8)
Median (IQR) age, yr	6.9 (3.7-12.9)	5.9 (3.6-9.9)	11.4 (6.3-16.2)	14.5 (3.3-16.5)
Female, N(%)	77 (43)	58 (45)	16 (38)	3 (38)
Race, N(%)				
White	46 (26)	31 (24)	12 (29)	3 (38)
Black	23 (13)	15 (12)	7 (17)	1 (13)
Asian/Pacific Islander	31 (17)	29 (23)	2 (5)	0
Other/unk	79 (44)	44 (41)	21 (49)	4 (49)
Hispanic ethnicity, N(%)	57 (32)	37 (29)	17 (41)	3 (38)
Baseline lab results				
Median (IQR) serum creatinine, mg/dL	0.4 (0.3-0.7)	0.4 (0.3-0.6)	0.7 (0.4-1.3)	0.4 (0.4-0.9)
Missing, N(%)	67 (37)	46 (36)	20 (48)	1 (13)
Median (IQR) serum albumin, mg/dL	1.7 (1.5-2.2)	1.6 (1.5-2.1)	2.0 (1.6-2.7)	2.1 (1.7-3.8)
Missing, N(%)	86 (48)	56 (43)	26 (62)	4 (50)
Total cholesterol, mg/dL, N(%)				
<=240	10 (5)	8 (6)	2 (5)	0
>240	56 (31)	43 (33)	10 (24)	3 (38)
Missing	113 (63)	78 (61)	30 (71)	5 (62)

Conclusions: Leveraging electronic health records and linked data sources, we identified a population-based cohort of children with primary NS that will provide a unique platform for describing the natural history of NS and identifying predictors of adverse outcomes.

FR-PO433

Abatacept Treatment and B7-1 Immunostaining in Patients with Primary and Post-Transplant FSGS Rutger J. Maas,[1] Brigith Willemsen,[2] Henry Dijkman,[2] Catharina M. Haring,[3] Jeroen Deegens,[1] Jack F. Wetzels.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Nephrology, Deventer Hospital, Deventer, Netherlands.*

Background: Podocyte B7-1 expression has been implicated in the pathogenesis of idiopathic nephrotic syndrome for many years. Recently, podocyte B7-1 was described as a potential therapeutic target by demonstrating efficacy of B7-1 blocking agent abatacept in five patients with primary and post-transplant FSGS (Yu et al. New Engl J Med 2013). The authors speculated that patients who will respond to abatacept can be identified by positive B7-1 immunostaining on kidney biopsy. Here, we report our experience with abatacept and B7-1 staining in patients with FSGS.

Methods: Patients with no or partial proteinuria remission after plasmapheresis for treatment of FSGS received abatacept (2 or 3 doses of 10 mg/kg). After several trials of unsuccessful immunofluorescence staining, we performed B7-1 immunohistochemistry on paraffin embedded tissue with a primary antibody mouse anti CD80 (R&D systems).

Results: Three patients with post-transplant FSGS, and one patient with FSGS in the native kidney (Table, Patient 4) were treated with abatacept. All transplant patients had developed nephrotic proteinuria immediately after transplantation. Patient 1 had been treated with plasmapheresis for many years, and was previously unresponsive to B7-1 blocking agent belatacept. None of the patients had proteinuria remissions after abatacept, nor did we observe positive podocyte B7-1 immunostaining.

Conclusions: In our hands B7-1 staining was absent in patients with FSGS. Our data caution against too much optimism regarding the efficacy of abatacept.

Clinical Characteristics of FSGS patients treated with abatacept

Variable	Patient 1	Patient 2	Patient 3	Patient 4
Gender	Female	Male	Male	Male
Age	39	27	20	19
Previous treatment for FSGS	PP	PP	PP	Steroid; MMF; rituximab; PP
Time between proteinuria onset and abatacept	4 years	17 days	17 days	4 years
Urinary PCR before / after treatment (g/10 mmol)	16 / 15	7.2 / anuric	20.1 / 8.7	4.5 / 5.7
Screat before / after treatment (μmol/L)	115 / 100	dialysis	218 / 204	81 / 86

PP = plasmapheresis

Steroid Resistant Nephrotic Syndrome: A Prospective, Open Label Study of the Safety and Efficacy of Combination Tacrolimus and ACTHar Gel Therapy

James A. Tumlin,[1] Claude Mabry Galphin,[1] Brad H. Rovin.[2] *[1]Univ of Tennessee College of Medicine, Chattanooga, TN; [2]The Ohio State Univ, Columbus, OH.*

Background: Steroid resistant nephrotic syndrome (SRNS) in adults is associated with increased risk for progression to ESRD. Tacrolimus is a calcineurin inhibitor (CNI) that is an alternative to steroids, but is associated with progressive fibrosis and loss of GFR. ACTHar gel has shown benefit in the treatment of SRNS. To investigate additive effects, we followed 23 SRNS patients receiving combination therapy with Tacrolimus and ACTHar Gel.

Methods: 23 patients with SRNS (IMGN 8, 11 FSGS and 4 other) receiving ACE/ARB and 8 weeks of oral steroids prior to combination therapy of ACTH and Tacrolimus. Eleven patients received 2 or more drug therapies. Of the 23, 17 (71%) initially received ACTH followed by Tacrolimus. Duration of ACTH/TAC therapy averaged 6.2 months [range 1-12 months]. Complete or partial responses were defined as UP/Cr ratio of < 0.30 or > 50% reduction in pre-ACTH/TAC proteinuria, respectively.

Results:

Table-1	Number	Age	Baseline	Peak	ACTH	ACTH+ TAC
Responder	17	Yrs	6.2±1.4	11.0±1.4	3.3±1.0	1.4±0.4
IMN	6	58±3	6.6±2.3	13.1±2.7	4.9±1.2	1.2±0.5
FSGS	9	67±5	4.3±2.3	10.4±1.4	2.6±0.5	1.7±0.9
Other	2	58±1	9.9±5.6	12.4±3.0	0.3±0.2	0.63±0.7
Non-Responder	6	52±5	5.7±1.6	11.6±1.5	7.5±1.5	7.8±1.5
IMN	3	46±7	6.3±2.2	11.6±2.9	7.6±2.5	9.2±4.3
FSGS	3	52±8	6.0±2.3	11.8±0.5	7.4±1.6	7.3±1.6

Of the 23 patients, 6 (26%) achieved a complete response; a partial responses were observed in 11 (48%) for an overall response of 74%. Proteinuria levels (expressed as a UP/Cr ratio) before and after treatment are listed in the Table. There was no difference in the rate or time to complete or partial remission between IMGN and FSGS (IMGN: 75%;7.0+1.5mths; FSGS: 82%;6.1+0.8 mths).

Conclusions: Combination therapy with ACTHar Gel and Tacrolimus achieved a 75% and 82% complete or partial response rate in patients with steroid resistant IMGN and FSGS patients respectively. The mean time to partial response was 6.2 months, but could range up 12 months. Combination therapy ACTH and Calcineurin inhibitors may offer an effective alternative therapy to SRNS.

FR-PO435

Treatment of Nephrotic Syndrome Secondary to Primary FSGS – Prednisolone or Tacrolimus? A Two Centre Experience

Hannah R. Wilson,[1] Thomas M. Connor,[2] Tom Cairns,[2] Mona Saleh Wahba,[1] Marie B. Condon,[1] Megan Griffith.[2] *[1]St. Helier Hospital, London, United Kingdom; [2]Hammersmith Hospital, London, United Kingdom.*

Background: Focal segmental glomerulosclerosis (FSGS) is a significant cause of end-stage renal failure. Patients with nephrotic syndrome have a worse prognosis. Current guidelines advise prolonged prednisolone (pred) at 1mg/kg. Tacrolimus (Tac) is an alternative for patients, but long-term therapy is often necessary, and there are concerns about toxicity.

Methods: Retrospective review of all patients with nephrotic syndrome secondary to primary FSGS treated with a minimum of 12 mths follow-up at 2 centres. All patients received standard therapy with max tolerated ACEi +/- ARB. Complete remission (CR) was defined as normal serum albumin with PCR <50; partial remission (PR) as proteinuria ≤50% baseline. Results described as Median (Range). p value <0.05 significant.

Results:

Demographics	Pred n=15	Tac n=23	p value
Age	50 (19-75)	45 (19-78)	ns
Gender	8M, 7F	12M, 11F	ns
Ethnicity Caucasian Afro-carib Asian	 12 1 2	 9 5 9	ns

Response to primary agent (pts) Remission PR CR	 60% (9) 60% (9) 33% (5)	 91% (21) 91% (21) 87% (20)	 <0.05 <0.05 <0.005
Time to remission (wks)	PR 8 (3-40) CR 10 (5-44)	PR 9 (2-52) CR 25 (3-117)	ns ns
Relapse	22% (2)	25% (5)	ns
ESRF	26% at 1,13,19,69 mths	0	<0.05
Creat latest f/u	92 (61-390)	92 (54-234)	ns
Adverse events Deaths Diabetes/Insulin Severe Infection	 1 (lung ca) 3 4	 1 (colon ca) 0 1	<0.01

Conclusions: In the Tac cohort a higher remission rate was demonstrated and a suggestion of fewer adverse events although numbers are small. However the baseline parameters show the GFR was significantly lower in the prednisolone group. Patients treated with Tac had a longer duration of treatment but appeared to have a better adverse event profile overall. A randomised controlled trial is required to investigate this further.

FR-PO436

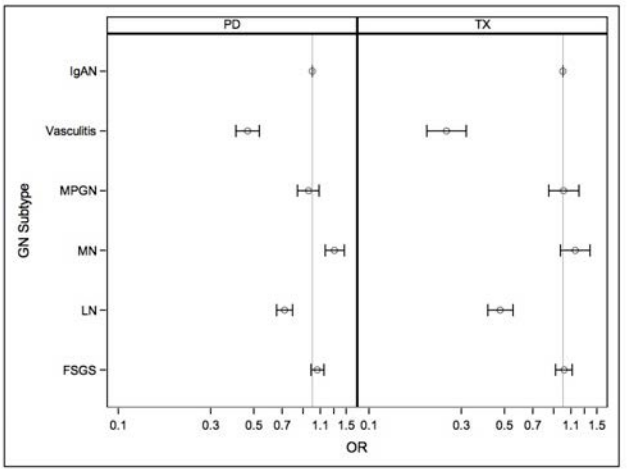
Differences in Initial End Stage Renal Disease (ESRD) Treatment Modality Across Glomerulonephritis Subtypes

Michelle M. O'Shaughnessy,[1] Maria E. Montez-Rath,[1] Richard A. Lafayette,[1] Wolfgang C. Winkelmayer.[2] *[1]Div of Nephrology, Stanford Univ School of Medicine; [2]Section of Nephrology, Baylor College of Medicine.*

Background: Kidney transplantation (Tx) is the treatment of choice for end-stage renal disease (ESRD). Hemodialysis (HD) and peritoneal dialysis (PD) outcomes are largely equivalent. Whether access to these modalities is equal across glomerulonephritis (GN) subtypes has not been established.

Methods: We identified all patients in the US Renal Data System 18-75 years who initiated ESRD therapy with Tx, HD, or PD (1996-2011) and had ESRD attributed to 6 GN subtypes [focal segmental glomerulosclerosis (FSGS), IgA nephropathy (IgAN), membranous nephropathy (MN), membranoproliferative GN (MPGN), lupus nephritis (LN), vasculitis]. Odds ratios (ORs) for PD vs HD and for Tx vs HD were computed using multinomial logistic regression (IgAN as reference group), with multivariate adjustment for demographic, socioeconomic, and comorbidity differences.

Results: Among 75,278 patients studied, demographic, socioeconomic, and comorbidity characteristics differed considerably across GN subtypes. In unadjusted analyses, patients with FSGS, MN, MPGN, LN, and vasculitis were significantly less likely to receive Tx or PD as a first ESRD treatment modality than patients with IgAN: OR for Tx 0.52, 0.35, 0.48, 0.23, and 0.13, respectively; OR for PD 0.77, 0.66, 0.59, 0.48, and 0.30, respectively (all p<0.0001). After adjustment, differences were attenuated but patients with secondary GN subtypes (LN, vasculitis) remained significantly less likely to receive Tx or PD as compared to patients with IgAN (figure).



Conclusions: Patients with ESRD attributed to secondary GN subtypes (LN, vasculitis) are significantly less likely to receive Tx or PD as an initial ESRD treatment than patients with primary GN subtypes. The clinical appropriateness and sequelae of this apparent inequity must be determined.

Non Collapsing Focal and Segmental Glomerulosclerosis in Patients with HIV Julien Hogan,[1,2] Claire Cartery,[2] Emmanuelle M. Plaisier.[2] *[1]Pediatric Nephrology, Robert Debré Hospital, Paris, France; [2]Nephrology and Dialysis, Tenon Hospital, Paris, France.*

Background: With the improvement of the treatments against HIV, non collapsing focal and segmental glomerulosclerosis (FSGS) has become more frequent than HIV associated nephropathy (HIVAN). However, the physiopathology of non-collapsing FSGS among HIV patients remains poorly understood. We thus aimed to compare patients with HIV and non collapsing FSGS with patients with HIVAN and with non HIV patients with FSGS.

Methods: HIV patients with a kidney biopsy in our center between 2000 and 2012 (24 non collapsing FSGS and 13 HIVAN) and two control groups (10 primary and 12 secondary FSGS) were included. Clinical and biological data were collected; viral load in serum and urine was assessed by PCR and histological exam was performed together with immunohistochemical staining for PCNA to study epithelial cells proliferation.

Results: Clinical and biological features of HIV patients with non-collapsing FSGS were close to those of controls with secondary FSGS. Among HIV patients, the prevalence of cardiovascular risk factors was greater in those with non collapsing FSGS than in those with HIVAN (79% vs. 38%, p=0.01) but was comparable to the one in controls with secondary FSGS (100% vs. 79%, NS). HIV patients with non collapsing FSGS and controls with secondary FSGS had more frequently arteriolosclerosis on the biopsy than patients with HIVAN (75% and 82% vs 36%, p<0.01). Visceral epithelial cells expression of PCNA showed that, despite a stronger staining in collapsing lesions, it can be found among all patients groups and in any FSGS lesion type. The majority of HIV patients with non collapsing FSGS had undetectable viral load in serum and urine.

Conclusions: Major clinical, biological and histological differences between HIV patients with non collapsing FSGS and HIVAN support the hypothesis of two distinct physiopathological entities. They are striking similitudes between non collapsing FSGS in HIV patients and secondary FSGS found in patients with polyvascular disease. Non collapsing FSGS in HIV patients might be due to nephronic reduction secondary to vascular lesions in an ageing population with major metabolic abnormalities associated with antiviral drugs.

FR-PO438

Diabetic Glomerulosclerosis or Idiopathic Nodular Glomerulosclerosis – Role for Insulin Resistance Manish Anand, Mehri Mollaee, Ravi Sunderkrishnan, Andres Rodrigo Caero, Mehrdad Hamrahian. *Nephrology, Thomas Jefferson Univ Hospital.*

Background: Diabetic nephropathy (DN) is characterized histologically by nodular mesangial sclerosis, a thickened glomerular basement membrane, and hyalinized arterioles. Differential diagnoses by light microscopy (LM) include membranoproliferative glomerulonephritis, amyloidosis, monoclonal immunoglobulin deposition disease, and fibrillary or immunotactoid glomerulopathy. These can readily be excluded by special stains, immunofluorescence (IF) and electron microscopy (EM). Idiopathic nodular glomerulosclerosis (ING) is the term used to denote classic DN confirmed by LM, IF, and EM, but in the absence of diabetes mellitus (DM). Case reports suggest insulin resistance (IR) as a possible cause.

Methods: Data was collected retrospectively on 21 cases of diabetic glomerulosclerosis or ING biopsied due to proteinuria (1+ on urinalysis to 12.3 grams/day), with or without renal insufficiency (creatinine 0.6-4.4mg/dL).

Results: 13 patients were male with majority of patients being African American (10) and non-Hispanic white (7). 1 patient was post-renal transplant and another post-liver transplant. None of these patients were diagnosed with DM, although some had intermittently elevated blood glucose and borderline HbA1c. All patients had hypertension, but only 5 were active tobacco users and 8 were former smokers. BMI range was 21-43kg/m^2. Hemoglobin A1c range was 4.6-6.1% in 10 patients and 6 patients denied DM by telephone survey. The remaining 5 patients had no history of DM per records with few elevated random plasma glucose levels noticed on steroids. None of them fulfilled current diagnostic criteria for DM. Metabolic syndrome (MS) defined by Adult Panel III criteria was evident in 11 patients.

Conclusions: The pathogenesis of ING remains unclear. It involves the interplay of hypertension, obesity, and heavy smoking. We feel that IR is critically important, whether evident as subtle, prediabetic elevations of blood glucose, MS, or elevated HOMA-IR score being the only manifestation. Insulin sensitivity assessed by HOMA-IR score is possibly an important predictive factor in pathophysiology of ING and needs to be tested routinely.

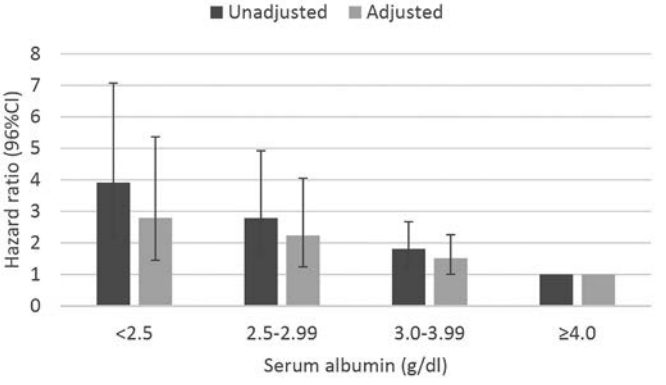
FR-PO439

Association of Serum Albumin Level and Venous Thromboembolic Events in Seven-Thousand Patients with Nephrotic Syndrome Geeta G. Gyamlani,[1] Miklos Zsolt Molnar,[2] Jun Ling Lu,[2] Keiichi Sumida,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[1,2] *[1]VA Medical Center, Memphis, TN; [2]Univ of Tennessee Health Science Center, Memphis, TN; [3]Univ of California, Irvine, CA.*

Background: Prior studies have shown that low serum albumin in patients with nephrotic syndrome (NS) is associated with an increased risk of venous thromboembolic (VTE) events. This is based on small studies with a low number of thromboembolic events and short term follow-up.

Methods: From a nationally representative cohort of over 3 million US veterans with baseline estimated glomerular filtration rate (eGFR) ≥60 ml/min/1.73m^2,we identified 7037 patients with NS based on ICD9 codes. Association between serum albumin and risk of incident VTE events (based on ICD9 codes) was assessed using Cox regression analysis with adjustments for age, gender, race, comorbidities, eGFR, BMI and anticoagulant treatment.

Results: Mean age was 57±11 years, and patients were 96% male, 32% African-American and 60% diabetic. There were a total of 158 VTE events over a median follow-up was 8.1 years; 16 events (4.1%, event rate (ER): 8.5/1000 patient-years(PY)) in patients with albumin <2.5 g/dl, 18 events (3.4%, ER: 5.7/1000 PY) in patients with albumin 2.5-2.99 g/dl, 89 events (2.5%, ER: 3.4/1000 PY) in patients with albumin 3-3.99 g/dl and 35 events (1.4%, ER: 1.9/1000 PY) in patients with albumin ≥4 g/dl. Compared to patients with albumin ≥4 g/dl, those with albumin levels of 3-3.99 g/dl (adjusted HR:1.51; 95%CI:1.01-2.26), 2.5-2.99 g/dl (2.24, 1.24-4.05) and < 2.5 g/dl (2.79, 1.45-5.37) experienced a linearly higher risk of VTE events.



Conclusions: Lower serum albumin is a strong incremental risk factor for VTE events in NS. The risk increases proportionately with declining albumin levels. Our finding may have important clinical implications regarding initiation and duration of prophylactic anticoagulation.

FR-PO440

Hypercoagulopathy Is Directly Correlated with Disease Severity in Nephrotic Syndrome Amanda P. Waller,[1] Samir Parikh,[2] Brad H. Rovin,[2] William E. Smoyer,[1] Marvin T. Nieman,[3] Matthias Kretzler,[4] Bryce A. Kerlin.[1] *[1]Clin/Trans Research, Nationwide Children's, Columbus, OH; [2]Nephrology, Ohio State Univ, Columbus, OH; [3]Pharmacology, Case Western Reserve Univ, Cleveland, OH; [4]Nephrology, Univ of Michigan, Ann Arbor, MI.*

Background: Nephrotic syndrome (NS), a leading cause of end stage kidney disease, is characterized by massive proteinuria, hypoalbuminemia, and an increased risk for venous thromboembolism (VTE). We recently reported that hypercoagulopathy is proportional to the severity of both proteinuria and hypoalbuminemia in two animal models of NS. This study was designed to determine if this relationship translates to human NS.

Methods: Aliquots of plasma anticoagulated with 0.32% (final concentration) sodium citrate were obtained from the NEPTUNE biorepository (n=147 patients), along with corresponding clinical lab data (e.g. urine protein:creatinine (uP:C), serum albumin (sAlb)). Samples collected from a local patient cohort (n=21) were used to validate biorepository

specimen integrity. Endogenous thrombin potential (ETP) was determined using the Technothrombin TGA kit and RC Low reagent after 2:1 dilution with buffer. Plasma antithrombin (pAT) activity was measured by the amidolytic method.

Results: As expected, NEPTUNE patients exhibited a wide range of proteinuria values (median (range) uP:C: 1.85 mg/mg (0-17.6)). Hypoalbuminemia and proteinuria severity in these patients were proportional to ETP (R^2=0.252 & 0.128, respectively, P<0.001). These correlations were stronger in the subset of patients with uP:C>2 (R^2=0.331 & 0.157, respectively, P<0.001). Plasma AT activity was also significantly correlated to hypoalbuminemia and proteinuria severity (R^2=0.125 & 0.031, P<0.001 & 0.03, respectively). There was no correlation between AT activity and ETP. Results were similar in the validation cohort.

Conclusions: Both hypoalbuminemia and proteinuria severity in humans with NS is significantly, albeit weakly, correlated to ETP (an established marker of thrombotic risk). Adjusting these data for confounding clinical variables (e.g. smoking status, BMI, etc.) may aid in the modeling and development of evidence-based cut-offs to guide indications for prophylactic anticoagulation.

FR-PO441

Successful Social Media Recruitment into the NephCure Kidney Network, a Rare Disease Patient Registry Laura H. Mariani,[1] Joanna Dauber,[2] Chelsey Fix,[2] Alyssa Fisher,[2] Jane Shen,[2] Lalita Subramanian,[1] Marilyn Hailperin,[2] Elizabeth L. Cope.[1] *[1]Arbor Research Collaborative for Health; [2]NephCure Kidney International.*

Background: Participation in clinical research for primary Nephrotic Syndrome (NS) has been limited by the rarity of the disease. There is growing interest in leveraging social media to expand demographic and geographic reach for recruitment. Because of the isolating nature of rare diseases, patients turn to social media for support, creating online communities that, if accessible, could potentially serve as a resource for recruitment.

Methods: The NephCure Kidney Network (NKN) is a web-based patient opt-in registry for primary NS. Participants provide data, including kidney disease history, demographics, and research participation preferences. Recruitment efforts launched in March 2014 relied on email campaigns to contacts of the patient advocacy group, NephCure Kidney International (NKI), but then expanded in September 2014 to include social media. Weekly posts were made to NKI's Facebook page, with analysis of performance based on impressions (# of people reached) and engagements (likes, clicks, shares, comments). Relationships with other closed Facebook kidney disease groups were established and posts made to their sites.

Results: 45,151 impressions and 2,927 engagements were made from 9/2014-6/2015. Relationships were made with 54 kidney disease groups (>15,000 members) from which to find NS patients. Engagements were highest on posts focusing on patient-centeredness in research and lifestyle. 414 patients (51% female, 47% <18 yo, 22% racial/ethnic minority) from 27 countries enrolled between 3/2014 and 6/2015, with 27% of enrollees having no previous engagement with NKI. 94% reported a willingness to be contacted about research, including 77% willing to donate a biospecimen. However, only 16% currently or previously participated in a clinical trial. 78% were willing to travel >50mi to participate in a study and 34% were willing to travel >500mi.

Conclusions: A recruitment strategy which includes social media is an efficient, cost-effective opportunity to engage rare disease patients across a wide geography, including those who have not previously participated in research.

FR-PO442

The Expression of Podocyte Protein PREX2 in Glomerular Diseases Anna Levin,[1] Julia Wijkstrom,[1] Jenny Hulkko,[1] Jenny C. Nystrom,[2] Kerstin Ebefors,[3] Annette Bruchfeld,[1] Jaakko Patrakka,[4] Kjell Hultenby,[5] Annika Wernerson.[1] *[1]CLINTEC, Karolinska Inst (KI), Stockholm, Sweden; [2]Dept of Physiology, Sahlgrenska Academy, Gothenburg, Sweden; [3]Dept of Molecular and Clinical Medicine, Sahlgrenska Academy, Gothenburg, Sweden; [4]Dept of Medicine, KI, Stockholm, Sweden; [5]LabMed, KI, Stockholm, Sweden.*

Background: Phosphatidylinositol-3,4,5-triphosphate-dependent Rac exchange factor 2 (PREX2)is a 183 kDa protein that functions as a RAC guanine nucleotide exchange factor (GEF), activating Rac proteins. It has been discovered in several tissues, e.g. brain, lung, liver and kidney. The specific function of PREX2 in the kidney is unknown. The aim of the present study was to investigate the localization of PREX2 in the kidney and the possible role in renal disease.

Methods: RT-PCR, Western Blot and immunohistochemistry (IHC) was used to identify the localization of PREX2 in renal tissue. The mRNA expression in diseased kidney was analyzed by microarrays on isolated glomeruli from patients with IgA Nephropathy (IgAN), Membranous Nephropathy (MN) and normal tissue. Immuno electron microscopy (iEM) was used to semiquantify PREX2 in renal biopsies from patients with IgAN (n=6), Minimal Change Nephropathy (MCN, n=5) and control tissue from healthy kidney donors (n=5). The morphology was correlated to proteinuria at time of biopsy.

Results: RT-PCR and Western Blot showed the presence of PREX2 in glomerulus. IHC and iEM revealed that PREX2 was localized to podocyte foot processes. In disease samples, mRNA levels were not changed in IgAN and MN. Semi-quantitative iEM showed a significantly lower expression of PREX2 in IgAN and MCN compared to controls. A tendency towards a negative association between PREX2 and proteinuria was seen, although this was not significant.

Conclusions: We found that PREX2 is a new podocyte-associated protein. Although no difference in mRNA levels were found, the expression of PREX2 was significantly lower in IgAN and MCN compared to controls. The function of PREX2 in the glomerular filtration barrier will now be further investigated in an extended patient cohort and in genetically modified animals.

FR-PO443

Urinary and Serum Soluble Urokinase Receptor Levels Predicts the Therapeutic Response of Nephrotic Syndrome Keiji Fujimoto, Yuki Matsui, Norifumi Hayashi, Junko Imura, Hiroki Adachi, Hideki Yamaya, Hitoshi Yokoyama. *Div of Nephrology, Kanazawa Medical Univ, Uchinada, Ishikawa, Japan.*

Background: It is necessary to develop noninvasive biomarkers to predict the treatment response for nephrotic syndrome (NS), and to differentiate their histological types in the initial phase.

Methods: The subjects were 32 patients with primary NS [8 with focal segmental glomerulosclerosis (FSGS), 12 with minimal change nephrotic syndrome (MCNS), 10 with membranous nephropathy (MN), and 2 with membranous proliferative glomerulonephritis]. Using ROC analysis, we examined whether or not it is possible to differentiate refractory NS from non-refractory NS, and MCNS from FSGS based on the pretreatment values of clinical markers [urinary protein (UP), serum/urinary soluble urokinase receptor (s-/u-suPAR), urinary L-FABP, and eGFR], and values and changes (Δ) after 2 months (2M). We also examined the renal expression of activated b3 integrin (AP-5) by immuno-staining in primary NS and normal tissues.

Results: The following parameters were useful for differentiating refractory NS from non-refractory NS: 2MUP (AUC=0.968, p=0.001), 2Ms-suPAR (AUC=0.913, p=0.002), D2Mu-suPAR (AUC=0.906, p=0.007), D2Ms-suPAR (AUC=0.881, p=0.005), and D2MUP (AUC=0.833, p=0.014). On the other hand, D2Ms-suPAR (AUC=0.905, p=0.007) and D2Mu-suPAR (AUC=0.816, p=0.048) were useful for differentiating MCNS from FSGS. In addition, u-suPAR before treatment was positively correlated with UP (ρ=0.501, p=0.003) and urinary L-FABP (ρ=0.427, p=0.017). The expression of activated b3 integrin was primarily strong in the proximal tubular epithelial cells in FSGS or MN, but, weak in MCNS and normal tissues. Otherwise, there was no expression of activated b3 integrin on podocytes in both normal and diseased tissues.

Conclusions: It may be possible to evaluate the treatment response of NS and to differentiate MCNS from FSGS based on changes in s/u-suPAR within 2 months after the start of treatment. As a mechanism involved in proteinuria in NS patients, u-suPAR may inhibit protein reabsorption in the proximal tubules through the activation of b3 integrin.

FR-PO444

Turkish Atypical Hemolytic Uremic Syndrome Registry: Initial Pediatric Results Nesrin Besbas,[1] Oguz Soylemezoglu,[2] Bora Gülhan,[1] Z.birsin Özçakar,[3] Emine Korkmaz,[4] Fatih Ozaltin.[1,4] *[1]Pediatric Nephrology, Faculty of Medicine Hacettepe Univ, Ankara, Turkey; [2]Pediatric Nephrology, Faculty of Medicine Gazi Univ, Ankara, Turkey; [3]Pediatric Nephrology, Ankara Univ Faculty of Medicine, Ankara, Turkey; [4]Nephrogenetics Laboratory Dept of Pediatric Nephrology, Hacettepe Univ, Ankara, Turkey.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare, genetic, life-threatening disease of chronic complement activation leading to systemic thrombotic microangiopathy and end-organ damage. The national aHUS registry was initiated in November 2013 and collects information on the progression and treatment of disease.

Methods: A clinical diagnosis of aHUS is required for inclusion. Demographic, medical histories, treatments, efficacy and safety outcomes data are collected initially and every 3 months.

Results: By May 15, 2015, 122 pediatric patients (55.8% female and 44.2 % male) were enrolled from 22 centers covering all the country. Mean age at diagnosis was 4.38±4.23 years. A total of 90 patients (74.6%) had oliguria or anuria at the time of diagnosis. Serum complement 3 was low in 49 patients (40.2%). Neurologic system involvement was present in 34 patients (27.2%). Renal biopsy was performed in 37 patients (30.7%). Renal replacement therapies (RRT) were initiated in 61.5 % of the patients at administration where only 10% of the patients were discharged with RRT. Genetic studies including the complement pathway, DGKE and factor H antibodies were studied in 73% of patients. Plasma infusion or plasma exchange was the initial treatment in 82% of patients and 59 % of patients (n=72) had eculizumab treatment. At the time of discharge after initial management, 78 patients (63.9%) and 92 patients (75.4%) achieved renal and hematological remission, respectively. Four patients died at the acute stage of the disease. Mean duration of follow-up was 2.28±2.30 years. During follow-up, eculizumab was stopped in 18 patients and re-started in four of them due to relapse.

Conclusions: The pediatric aHUS Registry will provide data to help increase our knowledge of the aHUS patient with different genetic background and also evaluate the long-term safety and efficacy of treatment options including the eculizumab.

FR-PO445

Long-Term Outcomes of Thrombotic Microangiopathy Treated with Plasma Exchange – A Systematic Review Bashiar Thejeel,[1,2] Amit X. Garg,[2,3,4] Aiden Liu,[2] Arthur Iansavichus,[2] Ainslie M. Hildebrand.[2,4] *[1]Schulich School of Medicine; [2]Kidney Clinical Research Unit, London Health Sciences Centre; [3]Epidemiology and Biostatistics, Western Univ; [4]Nephrology, Western Univ.*

Background: With the adoption of plasma exchange as standard treatment for thrombotic microangiopathy, more patients are surviving and longer-term outcomes have greater relevance.

Methods: We conducted a systematic review of observational studies between 1980 and 2013 that reported outcomes of adults with thrombotic microangiopathy at least 6 months after initiating plasma exchange. We searched several databases from 1980 to 2013 for eligible articles published in any language. We abstracted data in duplicate and assessed the methodological quality of each study using an assessment tool developed based on recommended validity criteria.

Results: We screened 6672 articles, reviewed 213, and included 34 studies totaling 1182 patients (study median [range], 24 [10-118]). The mean (or median) follow-up ranged from 6 months to 13 years. The cumulative incidence of relapse and mortality was highly variable and ranged from 3 to 84% and 0 to 61%, respectively. The incidence of other outcomes across 10 studies also varied (outcomes included hypertension, kidney disease, preeclampsia, stroke, seizure, severe cognitive impairment, and depression); in 3 other studies long-term neurocognitive function and health-related quality of life were significantly lower than the general population.

Conclusions: In summary, patients who survive an episode of thrombotic microangiopathy may be susceptible to long-term vascular complications including chronic kidney disease, but the magnitude of this risk and how to mitigate it remains unclear from prior studies.

FR-PO446

Eculizumab Prevents Thrombotic Microangiopathy in Atypical Hemolytic Uremic Syndrome Patients: Long-Term Follow-Up Jan Menne,[1] Yahsou Delmas,[2] Eric Rondeau,[2] Christoph Licht,[4] Jimmy Wang,[5] Chris Mix,[5] John F. Kincaid,[5] Francois Provot,[6] Larry A. Greenbaum,[7] Fadi Fakhouri.[8] *[1]Klinik für Nieren- und Hochdruckerkrankungen, Hannover, Germany; [2]CHU de Bordeaux, France; [3]Hôpital Tenon & Univ Paris VI, Paris, France; [4]Hospital for Sick Children, ON, Canada; [5]Alexion Pharmaceuticals, Inc., Cheshire, CT; [6]CHU de Lille, France; [7]Emory Univ, Atlanta, GA; [8]CHU de Nantes, France.*

Background: In 5 previous studies of patients (pts) with aHUS, ECU effectively treated and prevented thrombotic microangiopathy (TMA) and improved renal function and hematological parameters for up to 2 yrs.

Methods: An observational, multicenter, long-term follow-up study of aHUS pts treated with ECU in 5 prior clinical studies. The primary endpoint was exposure/follow-up TMA event rate post-parent study on-(ON) and off-treatment (OFF; among pts who discontinued ECU).

Results: 85 pts enrolled (**Table**); of these, 74 pts had ON and 37 pts had OFF treatment periods with median follow-up of 24.6 and 16.6 months, respectively. The TMA event rate was 6.7 per 100 pt-yrs for ON pts, and 23.5 per 100 pt-yrs for OFF pts. The rate of TMA in ON pts was greater in those not receiving on-label dosing (**Table**). OFF pts had higher eGFR at time of discontinuation than ON pts. Age, frequencies of higher-risk complement factor mutations and kidney transplant status were not different between ON and OFF pts. Treatment status and higher-risk mutations independently predicted TMA.

Conclusions: The TMA event rate was 3.5-fold higher after ECU discontinuation vs. on ECU. TMA event rates were lowest during on-label dosing, higher during off-label dosing, and highest off-treatment. Pts with aHUS have a progressive increase in the risk of TMA events during periods of reduced dosing and after discontinuation of ECU compared with on-label ECU dosing. Medical writing support – Kenyon Ogburn PhD, of Alexion.

Table. Baseline Demographics and Efficacy Outcomes

Baseline Demographics and Disease Characteristics	N=85[a]			
Age at first ECU infusion, median (range), years <12 years, n (%) 12–18 years, n (%) ≥18 years, n (%)	22.0 (0–80.0) 24 (28.2) 10 (11.8) 51 (60.0)			
Age at entering current study, median (range), years <12 years, n (%) 12–18 years, n (%) ≥18 years, n (%)	26.0 (1.6–81.6) 21 (24.7) 3 (3.5) 61 (71.8)			
Female sex, n (%)	52 (61.2)			
Identified complement regulatory protein mutation or autoantibody, n (%)	52 (61.2)			
Time from aHUS diagnosis to first dose (months), median (range)	5.21 (0–313.3)			
Time from current aHUS manifestation to first dose (months), median (range)	0.92 (0.0–47.4)			
Number of aHUS events, n (%) Single Multiple	54 (63.5) 31 (36.5)			
Total number of PE/PI sessions per pt, median (range)	11 (0.0–230.0)			
Dialysis at baseline, n (%)	29 (34.1)			
Prior renal transplant, n (%)	21 (24.7)			
Efficacy Outcomes	**OFF Treatment[a,b,c] (n=37)**	**ON Treatment[a,b] Reduced Dose and/or Frequency (n=30)**	**On-label Dosing (n=62)**	**All ON Treatment (n=74)**
TMA event rate[d,e]	23.5	12.3	4.1	6.7

Results as of February 10, 2015.
[a]Pts could be included in both the ON and OFF groups.
[b]One pt had TMA events while on both on-label and reduced dose and/or frequency of treatment.
[c]Includes 11 pts who did not receive ECU post-parent study.
[d]A TMA event was defined as the new occurrence of increased creatinine and/or LDH, and/or decreased platelet count, and/or the occurrence of signs or symptoms of TMA, and/or receipt of plasma therapy, blood transfusion, dialysis or kidney transplant secondary to TMA.
[e]The TMA event rate refers to the number of events per 100 pt-years.
aHUS, atypical hemolytic uremic syndrome; ECU, eculizumab; pt, patient; TMA, thrombotic microangiopathy.

An Update on Tailored Eculizumab Maintenance Treatment in Patients with Atypical Haemolitic Uremic Syndrome Gianluigi Ardissino,[1] Francesca Tel,[1] Sara Testa,[1] Ilaria Possenti,[1] Donata Cresseri,[1] Samantha Griffini,[1] Elena Grovetto,[1] Stefania Salardi,[1] Silvana Tedeschi,[1] Nicolò Borsa,[2] Massimo Cugno.[1] *[1]Center for HUS Management, Fondazione IRCCS Ca' Granda Policlinico, Milan, Italy; [2]Molecular Otolaryngology & Renal Research Laboratory, The Univ of Iowa.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a severe, systemic thrombotic microangiopathy often related to mutations in the genes encoding complement regulatory proteins. Since 2009, Eculizumab (ECU) has been successfully used in patients (pts) with aHUS. The standard maintenance treatment suggests ECU administration every two weeks (wks), life-long but the best treatment schedule is not yet defined. To update on our experience on individualized ECU treatment schedule for preventing relapses based on drug biological activity, with the rational of improving the patient's quality of life, reducing the risk of adverse reactions and reducing the heavy costs of the treatment.

Methods: Pts undergoing ECU treatment for aHUS at our Center were addressed to a progressive extension of the interval between ECU doses from the standard 2 wks to 3 or 4 wks with a strict monitor of global complement activity. AP50 was routinely determined before each ECU administration and the interval between doses was adjusted with the target of maintaining AP50<25%. Strict monitoring of indicators of disease reactivation, namely blood in the urine with home dipstick, was regularly performed.

Results: The interval between doses was extended in 33 pts (13 ≤ 18 yrs) with a median age of 28.1 yrs (5-62), 17 F, 21 with native kidney and 12 with graft. Identified mutations were: CFH:15; CFI:2; CD46:1; MCP:1; CFHR3-CFHR1 homoz. deletion with (3) or w/o (1) antiFHAb:4; multiple mutations:3; Idiopathic:7. In 19 pts the optimal interval between ECU doses was 4 wks while in 14 pts it was 3 wks. No relapses was observed over a cumulative observation period of 748 mos (mean 23 mos/pt).

Conclusions: In patients with aHUS, our experience supports the possibility of tailoring ECU maintenance treatment schedule based on global complement activity. In a cohort of 10 adult pts the described novel approach leads to an average estimated saving >2 million USD/yr.

FR-PO448

Chemokines as Potential Biomarkers of Renal Involvement in Scleroderma Edward Stern,[1,2] Voon Ong,[1] Aine Burns,[2] Robert J. Unwin,[2] Christopher Paul Denton.[1] *[1]Centre for Rheumatology, UCL, London, United Kingdom; [2]Centre for Nephrology, UCL, London, United Kingdom.*

Background: Renal disease in scleroderma (SSc) remains a major clinical challenge. Previous studies showed up to 50% of SSc patients have CKD. We sought to gain insight into the pathogenesis of SSc-CKD by examining markers of disease in serum and urine.

Methods: We collected urine and serum from 80 SSc patients, with or without renal disease, for comparison with patients with CKD of other causes (n=10) and healthy controls (n=12). We performed multiplex analysis of candidate markers of disease activity or severity in SSc and renal injury: MCP-1, MCP-3, IL-6, IL-18, TNFa, and VEGF.

Results: 40 SSc patients had CKD defined by eGFR and urinalysis. Serum MCP-1 was increased in SSc compared with controls, with SSc-CKD significantly lower than SSc without CKD. Mean serum MCP-1 was 132 pg/ml (95% CI 105-162) for SSc with normal renal function compared with 65 pg/ml in SSc-CKD (49-81, p<0.001 for this comparison). MCP-1 was not increased in CKD of other causes (mean 47 pg/ml, 23-85) compared with

controls (mean 53 pg/ml, 25-85, p=0.848). Conversely, urine MCP-1:creatinine ratio was higher in SSc-CKD (mean 64, 32-111) than in SSc with normal renal function (mean 23, 18-28, p=0.046). MCP-3 was upregulated in the urine of patients with SSc with or without CKD (mean MCP-3:creatinine ratio 3.6, 2.5-4.6) compared with healthy controls (mean 0.9, 0.5-1.4, p=0.016). There was no difference between groups in serum MCP-3.

Conclusions: This is the first study to measure MCP-1 and MCP-3 in the urine of SSc patients. Elevated urine MCP-1 in SSc-CKD suggests increased expression in the renal tract and may help define organ-specific effects of this potential pathogenic mediator that has previously been reported to be increased in serum in association with pulmonary complications. In contrast to MCP-1, other markers of SSc severity (e.g. IL-6) or renal injury (e.g. IL-18) did not differentiate between groups. Our findings support further investigation of urine concentrations of chemokines MCP-1 and MCP-3 as markers or mediators of CKD in SSc.

FR-PO449

Towards a Deeper Understanding of Fibrillary Glomerulonephritis: Clinicopathologic Analysis of Patients in a Long-Term Inception Cohort

Fernanda Payan Schober,[1] Caroline J. Poulton,[1] Yichun Hu,[1] Harsharan Kaur Singh,[2] Volker Nickeleit,[2] William Franklin Pendergraft.[1] *[1]UNC Kidney Center, UNC Chapel Hill, Chapel Hill, NC; [2]UNC Pathology, UNC Chapel Hill, Chapel Hill, NC.*

Background: Fibrillary glomerulonephritis is an uncommon primary glomerular disease. Accordingly, there are no clinical trials to guide treatment making this a challenging disease to manage. Here, we report clinical characteristics and treatment outcomes of patients with fibrillary glomerulonephritis diagnosed and/or treated at UNC or through the Glomerular Disease Collaborative Network and compare them to a previously published cohort from Mayo clinic†.

Methods: Patients were identified through the UNC Division of Nephropathology database. Clinical data were extracted from the electronic medical records starting at the time of diagnosis.

Results: There were 31 patients with fibrillary glomerulonephritis who were treated at UNC and another 245 patients who were diagnosed by the UNC Division of Nephropathology. Demographic and clinical data from the date of biopsy are displayed in the table.

	UNC (n=31)	UNC Path (n=245)	Mayo (n=66)	p-value
Sex Female (%) Male (%)	 19 (61%) 12 (39%)	 153 (62%) 92 (38%)	 36 (55%) 30 (45%)	0.487
Race white black other	 18 (60%) 8 (27%) 4 (13%)	 167 (68%) 38 (16%) 40 (16%)	 68 (95%) 2 (3%) 1 (2%)	< 0.0001
Age mean (%) 15-34 35-54 >54	 49.6 ± 10.4 4 (13%) 18 (58%) 9 (29%)	 56.7 ± 11.5 8 (3%) 91 (37%) 146 (60%)	 53 ± 12 1 (8%) 9 (39%) 12 (53%)	 0.0011 0.0049
Serum creatinine (mg/dl)	2.1 ± 1.2	3.3 ±3.4	2.1 ± 1.6	0.0041
24hr urine protein (gm)	6.5 ± 4.0	7.5 ± 28.2	5.6 ± 4.2	0.8454
Serum albumin (g/dl)	3.0 ± 0.9	3.1 ± 0.8	3.2 ± 0.7	0.4751

Conclusions: This clinicopathologic analysis of patients with fibrillary glomerulonephritis is the largest study of its kind in the literature to date. The patients in our cohort were more ethnically diverse than the Mayo clinic group but presented with similar degree of kidney impairment and nephrotic range proteinuria. Fibrillary glomerulonephritis is an understudied glomerular disease that portends a poor prognosis warranting the need for prospective multi-center treatment studies to determine durable therapeutic avenues.

FR-PO450

Clinical, Histologic, and Genetic Predictors of Response to MMF in C3 Glomerulopathy

Rupali Surendra Avasare,[1] Pietro A. Canetta,[1] Andrew S. Bomback,[1] Yasar Caliskan,[2] Yasemin Ozluk,[2] Gerald B. Appel.[1] *[1]Div. of Nephrology, Columbia Univ Medical Center, New York, NY; [2]Div. of Nephrology, Istanbul Faculty of Medicine, Istanbul; [3]Dept of Pathology, Istanbul Faculty of Medicine, Istanbul.*

Background: Treatment of C3 Glomerulopathy (C3G) with anti-complement therapy has yielded mixed results and there is no consensus on optimal treatment. We reviewed the experience of our C3G patients who received a course of mycophenolate mofetil (MMF) to determine predictors of treatment response.

Methods: In a retrospective chart review of patients with biopsy-diagnosed C3G, we identified 24 patients treated with a course of MMF (> 6 months) with >1 year follow-up. The primary outcome was either complete remission (stable GFR with decline in proteinuria to < 0.5 g/gCr) or partial remission (stable GFR with >50% decline in proteinuria to between 0.5 – 3.5 g/gCr) at last follow-up. Responders and nonresponders were compared by two-tailed T test or Mann-Whitney U test for continuous variables and Fisher exact test for categorical variables.

Results: There were 15 men and 9 women with 21 White and 3 Black patients. Median age was 27 years (IQR 21 – 37). Median creatinine was 1.17 (IQR 0.87 – 1.74) mg/dl, eGFR 59 (IQR 34 - 89) ml/min/1.73m^2. Median proteinuria was 3.6 g/gCr (IQR 1.6 – 7.7). Of 24 patients treated with MMF, 14 (58%) were responders (8 CR, 6 PR). 22 of 24 patients received steroids. The only variable associated with remission was elevated soluble membrane attack complex (sMAC) level (responders 100%, nonresponders 25%, p <0.05). Age, eGFR, proteinuria, hypocomplementemia, complement factor mutations or autoantibodies, interstitial fibrosis/tubular atrophy, location of deposits on electron microscopy, and presence/absence of immunoglobulin staining on IF were no different between responders and nonresponders.

Conclusions: 14 of 24 C3G patients treated with a course of MMF experienced remission. Elevated sMAC level was associated with response to MMF. While not a specific anti-complement therapy, MMF may be an effective treatment for some patients with C3G. This and other series suggest elevated sMAC may indicate treatment-susceptible disease.

FR-PO451

Genetic Sequences May Influence Clinical Progression or Clinical Presentations of C3 Glomerulopathy

Hostensia M. Beng, Basema I. Dibas, Hsiao Ling Lai, Guillermo Hidalgo. *Pediatrics, ECU, Greenville, NC.*

Background: We describe clinical course of 2 girls with C3 Glomerulopathy (C3 GN) with different genetic sequences and clinical courses.

Methods: Case 1(A). 12 yrs old AAF who presented with stage 2 HTN and & nephrotic range proteinuria (u. p/cr 4.6). A renal biopsy showed C3 GN. She received steroids. (HD) was initiated (s.cr 2.24 mg/dL, BUN 127mg/dL). She received 5 anti-hypertensive medications & 3 PE sessions. She had no improvement, D#29 she received Eculizumab 900 mg q wk & after 2 doses of Eculizumab, GFR improved and no longer required HD or PE. **Case 2** (B). 15 yrs old WF who presented at 7 yrs of age with hematuria, stage 2 HTN & nephrotic range proteinuria (u. p/cr 13). Kidney biopsy showed C3 GN. She received only Lisinopril and had maintained normal GFR without RRT/steroids. Though she continued to have nephrotic range proteinuria.

Results: Both presented with hematuria, HTN and nephrotic range proteinuria and their biopsies showed C3 GN, persistent nephrotic range proteinuria despite improvement in GFR and normal levels of FH, properdin, C5b9. Gene analysis for A showed deletion of CFHR3, CFHR1 and carry a variant of unknown significance in CFH and CFI. B in contrast had abnormal high complement plasma Bb antibody and 0% complement alternative pathway.

Conclusions: CFH competes with CFB for C3b binding, it impedes the formation of AP C3 convertase. CFH accelerates AP C3 convertase decay & is a cofactor for complement factor I (CFI) - mediated proteolysis of C3b. Complement regulatory protein with CFI cofactor activity. CFI is a serine protease encoded by the *CFI* gene on chromosome 4q25. Looking closely at the genetic difference in our two patients, we hypothesized that the genetic variants defects in CFH could have led to a more severe clinical presentation of A and mild disease presentation in B with AP alternative pathway abnormality. Genetic sequences may influence clinical manifestation/ progression of the C3GN.

FR-PO452

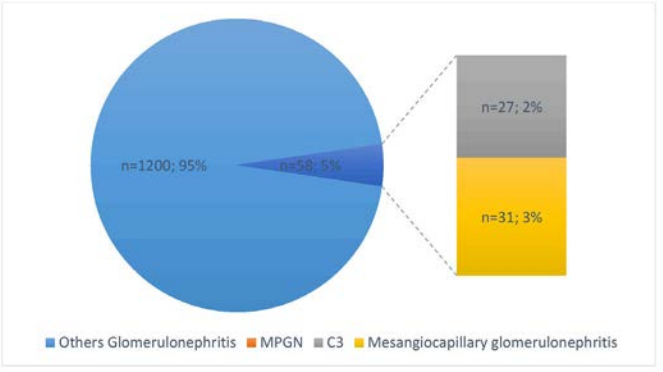
Membranoproliferative Glomerulonephritis C3 Deposits: Clinicopathological Study

Luis A. Castillo,[1] Eduardo I. Navarro,[2] Ismael Lopez,[2] Kelly Camacho,[2] Mayra Olivero,[2] Ismael Lopez,[2] Gustavo Aroca Martinez,[1,2] Henry J. Gonzalez Torres,[2] Raul Garcia.[1,2] *[1]Nephrology, Clínica de la Costa, Barranquilla, Atlántico, Colombia; [2]Medicine, Univ Simón Bolívar, Barranquilla, Atlántico, Colombia.*

Background: Membranoproliferative glomerulonephritis (MPGN) is a pattern of damage characterized in the light microscopy by mesangial hypercellularity, thickening of the glomerular basement membrane and mesangial interposition in the capillary wall. Recent advances in the understanding of its underlying pathogenesis led to a classification scheme based on the findings in the inmunofluorencencia. Alteration complement regulation has proven to be a risk factor for the development of MPGN.

Methods: Cross-sectional study. The data were extracted from NefroRed©, a software platform that contains the socio-demographic, anthropometric, clinical and laboratory data of 1200 patients with kidney biopsies from 2008 to 2014. It was selected for the study those patients that showed the pattern of glomerulonephritis and membranoproliferative and C3 deposits only or predominant. Each biopsy was studied by light microscopy and immunofluorescence, light microscopy included hematoxylin-eosin, PAS, and Jones y Tricrómico. Immunofluorescence was performed using antibodies directed against IgG, IgA, IgM, C1q, C3, albumin, fibrinogen, Lightweight Kappa and Lambda chains.

Results: Mean age of men was 42.3 years and women was 36.7 years. The minimum age was 18 years. The maximum age was 69 years; 51.8% (n = 14) of patients were women. The 1200 biopsies showed 58 injuries MPGN (5%) of these 58 cases only 27 (32%) lesions showed C3 deposits only or predominant.



Conclusions: 30% of patients with GMP have as pathogenic mechanism the complement activation with complement C3 deposition in the glomerulus. Our research group has found C3 deposition causally related to GMP. The most common clinical presentation is nephrotic syndrome.

FR-PO453

Steroids Alone for the Treatment of C3 Glomerulonephritis with Monoclonal Gammopathy

Insara Jaffer Sathick,[1] Ladan Zand,[1] Samih H. Nasr,[2] Sanjeev Sethi,[2] Fernando C. Fervenza,[1] Nelson Leung.[1,3] *[1]Div of Nephrology and Hypertension, Mayo Clinic; [2]Div of Anatomic Pathology, Mayo Clinic; [3]Div of Hematology, Mayo Clinic.*

Background: C3 glomerulonephritis (C3GN) is a rare disease with no trial data to guide treatment. In patients with C3GN with monoclonal gammopathy, steroids alone may be a viable treatment option.

Methods: We present our experience in managing C3GN with monoclonal gammopathy with prednisone.

Results: 5 patients presented to our institution from 2011 to 2014 with biopsy proven C3GN and underlying monoclonal gammopathy. Median age of this cohort was 63 years. Median estimated GFR by MDRD equation was 35.4 ml/min1.73m2 and median proteinuria was 2 g/day at presentation. All patients had IgG kappa monoclonal gammopathy. Patient 5 required renal replacement therapy but recovered renal function. All patients were treated with Prednisone 60mg/day tapering to zero in all except one. Patient 2 and 4 continue on 2.5-5mg/day. Median duration of follow up was 26.9 months. Median estimated GFR at follow up was 40.16 ml/min1.73m2. All patients showed improvement in proteinuria. 3/5 patients showed improvement in kidney function.

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5
Age	69	63	47	69	23
Gender	M	M	F	M	M
eGFR at presentation (MDRD) ml/min1.73m2	24.6	26.2	48.2	37.6	35.4
Proteinuria (g/day)	1.87	2	2.8	2.6	1
Serum M spike (g/dl)	0.6	0.5	0.5	1	0.8
Bone Marrow Biopsy	<5% kappa restricted cells	10%kappa restricted cells	Normocellular	<5%kappa restricted cells	Hypercellular
Presenting features	CKD, hematuria	CKD, hematuria	AKI, nephritic syndrome	CKD, hematuria	AKI with flu like symptoms
Alternative complement pathway evaluation	C3nephritic facor negative	Elevated soluble membrane attack complex (sMAC)	No abnormality	C3 nephritic factor positive, elevated sMAC	Heterozygous for CFH/DDD/C3GNassociated allele.C3 nephritic factor positive
Proteinuria on follow up (g/day)	0.14	0.55	0.82	0.62	0.01
eGFR on follow up	24.6	30	40	40	58

Conclusions: Our experience suggests that prednisone alone may be a treatment option in some patients with C3GN associated with a monoclonal gammopathy. Work up should be done to exclude a plasma cell neoplasm and inherited complement abnormalities.

FR-PO454

The National Study of Membranoproliferative Glomerulonephritis and C3 Glomerulopathy: Characterisation of the Initial United Kingdom Paediatric Cohort

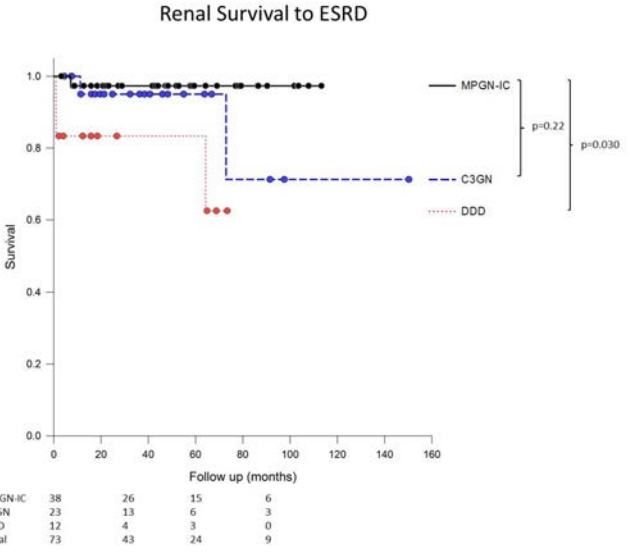
Edwin KS Wong,[1] Claire L. Harris,[2] Kevin J. Marchbank,[1] Isabel Y. Pappworth,[1] Rebecca Walters,[1] Hannah J. Lomax-Browne,[3] Daniel P. Gale,[4] Tim Goodship,[1] David Kavanagh,[1] Roger D. Malcomson,[5] Paul Morgan,[2] Matthew C. Pickering,[3] H. Terence Cook,[3] Sally A. Johnson.[1] *[1]Newcastle Univ; [2]Cardiff Univ; [3]Imperial College London; [4]Univ College London; [5]Leicester Royal Infirmary.*

Background: The National Registry of Rare Kidney Diseases (RaDaR) in the United Kingdom allows recruitment, research and longitudinal follow-up of patients with membranoproliferative glomerulonephritis (MPGN) and C3 glomerulopathy (C3G). The aim of the MPGN/C3G Rare Disease Group (RDG) is to deep phenotype and analyse complement abnormalities in a paediatric cohort of MPGN/C3G.

Methods: The MPGN/C3G RDG recruited patients with MPGN/C3G for central review of biopsies and clinical data, and studied complement abnormalities previously described in MPGN/C3G.

Results: 83 prevalent patients with MPGN/C3G were identified and centrally reviewed. 79 could be classified: 40 had immune-complex MPGN, 25 had C3GN and 14 had DDD. Complement abnormalities are shown in Table 1. Follow-up data on 73 patients is shown in Figure 1.

	MPGN–IC	C3GN	DDD
Low C3 at presentation	22/28 (79)	16/18 (89)	10/11 (91)
C3 nephritic factor	9/21 (43)	6/18 (33)	6/7 (86)
Anti-FH autoantibodies	7/39 (18)	3/24 (13)	3/14 (21)
Rare variant *(C3, FB, FH, FI)*	4/35 (11)	1/22 (5)	1/12 (8)
	Positive/number tested (%)		



Conclusions: RaDaR has facilitated the development of a large nationwide cohort of paediatric patients with MPGN/C3G who have now undergone deep phenotyping and genotyping centrally. Acquired complement abnormalities were common; rare genetic abnormalities were infrequent. Patients with DDD had the worst renal outcome. Ongoing recruitment and longitudinal follow up will clarify prognosis according to phenotype/genotype and allow stratification into future treatment studies.

FR-PO455

Plasma Neutrophil Gelatinase-Associated Lipocalin, Procalcitonin and C-Reactive Protein as the Predictor of Acute Pyelonephritis in Children with Febrile Urinary Tract Infections

Byungkwan Kim, Hyung Eun Yim, Kee Hwan Yoo. *Dept of Pediatrics, Korea Univ Medical Center, Seoul, Republic of Korea.*

Background: We have recently reported that plasma and urinary neutrophil gelatinase-associatedlipocalin (NGAL) levels are useful for the prediction of acute pyelonephritis (APN) in pediatric urinary tract infection (UTI). This study was aimed to determine the accuracy of NGAL measurements, compared with serum measurements of procalcitonin, C-reactive protein (CRP), and white blood cells (WBCs) in predicting APN and associated renal problems in children with febrile UTIs.

Methods: Total 138 children with febrile UTIs (59 APN, 79 lower UTI) were enrolled. Patients with renal failure, congenital urologic anomaly except vesicoureteral reflux

(VUR), and recurrent UTIs were excluded. Serum levels of NGAL, procalcitonin, CRP and WBC counts were measured at admittance. Laboratory, clinical, and imaging results were reviewed.

Results: Receiver operating curve analyses showed NGAL (area under the curve (AUC) 0.893), procalcitonin (AUC 0.855), CRP (AUC 0.879), and WBCs (AUC 0.654) had good diagnostic profiles for identifying APN (all $P < 0.05$). Using the best cut-off values (NGAL 117 ng/mL, procalcitonin 0.173 ng/mL, CRP 2.78 mg/dL, WBC 15,870/mm^3), odds ratios for APN were all highly increased after adjusting for age and gender (NGAL 41.2, procalcitonin 22.8, CRP 25.3, WBC 4.2). The sensitivity and specificity of plasma NGAL for diagnosing APN was the highest among all examined biomarkers (sensitivity 88.1%, specificity 84.8%). Univariate analysis showed that female gender, NGAL, procalcitonin, CRP, and WBCs were associated with APN (all $P < 0.05$). However, multivariate analysis revealed that only plasma NGAL was an independent predictorof APN ($P < 0.001$). NGAL, procalcitonin, and CRP levels also showed good predictive values for the presence of VUR (AUCs of NGAL, procalcitonin, and CRP 0.798, 0.756, 0.845).

Conclusions: Plasma NGAL, procalcitonin and CRP are sensitive predictors for identifying APN and VUR. Plasma NGAL can be more reliable than serum procalcitonin, CRP, and WBCs in predicting APN in children with febrile UTIs.

FR-PO456

A Prospective Evaluation of Renal Contrast-enhanced Ultrasound (CEUS) in the Detection of Pyelonephritis Florian Buchkremer,[1] Daniel Drozdov,[2] Werner C. Albrich,[3] Andreas H. Bock.[1] *[1]Div of Nephrology, Kantonsspital Aarau, Aarau, Switzerland; [2]Medical Univ Dept, Kantonsspital Aarau, Aarau, Switzerland; [3]Div of Infectious Diseases, Kantonsspital St. Gallen, St. Gallen, Switzerland.*

Background: Contrast-enhanced ultrasound (CEUS) has been described as a promising method for detecting acute pyelonephritis (PN) and its complications. We evaluated its value in diagnosis and risk stratification in the setting of a randomized controlled trial (RCT).

Methods: Immunocompetent adults with community-acquired urinary tract infection (UTI) presenting in the emergency department of Kantonsspital Aarau were enrolled in a RCT designed to evaluate the performance of a PCT/pyuria guided algorithm versus standard guidelines (Drozdov et al. BMC Medicine 2015). Outcomes included antibiotic exposure, duration of therapy, persistent infections and recurrences/re-hospi-talizations. As part of the protocol, all hospitalized UTI patients with fever and/or flank pain were to undergo renal CEUS in addition to standard greyscale and Doppler examination within the first 72h of admission. Findings suggestive of PN such as triangular, hypoechogenic, hyoperfused areas were recorded.

Results: Of 70 UTI study patients hospitalized with fever and/or flank pain, 41 (59%) underwent the ultrasound study. Dropout reasons included missing consent (5), early discharge (6) or technical (18). Examined and non-examined patients did not differ significantly in baseline characteristics or outcome. Findings suggestive of PN were found in 5/41 (12%). In 3 patients, this was evident in greyscale/Doppler already, in 2 additional patients, critical findings were only present in CEUS. The presence of PN-suggestive findings was not predictable from any baseline clinical characteristic. Patients with and without PN-suggestive findings did not appear to differ in outcome.

Conclusions: Ultrasound evidence of pyelonephritis is rare in patients hospitalized for UTI with fever or flank pain. Adding CEUS to basic greyscale and Doppler ultrasound may substantially increase the number of positive findings.

FR-PO457

ISN 0by25 AKI Global Snapshot Project: AKI Disposition Michael V. Rocco,[1] Ravindra L. Mehta,[2] Giuseppe Remuzzi,[3] Jing Zhang,[2] Melanie Godin,[4] Emmanuel A. Burdmann,[5] John Feehally,[6] Fredric O. Finkelstein,[7] Guillermo Garcia-Garcia,[8] Raul Lombardi,[9] Etienne Macedo.[5] *[1]Wake Forest U; [2]U California San Diego; [3]Mario Negri Inst; [4]Sherbrooke U; [5]U Sao Paulo; [6]U Leicester; [7]Yale U; [8]Hosp Civil de Guadalajara; [9]Servicio Medico Integral.*

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians about pts with AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Nephrology management of AKI was more common in LLMIC (85.1%) versus HIC (58.4%) or UMIC (58.1%). Location of pts 7 days after AKI diagnosis varied by GNI category (p<0.0001).

Location 7 days after AKI confirmation	Frequency	Percent	HIC	UMIC	LLMIC
ICU	567	16.5	23.5	17.2	7.2
Hospital ward	1980	57.5	57.1	58.2	56.8
Transfer to another hospital	51	1.5	0.7	1.5	2.3
Outpatient clinic	127	3.7	3.1	2.2	6.6
Other health facility			14 0.4 0.3	0.5	0.4
Home	612	17.8	13.8	17.2	23.3
Rehab/Nursing home	10	0.3	0.8	0.1	0
Unknown	84	2.4	0.8	3.2	3.3

AKI recovery was more often complete in LLMIC (34.5%) than in HIC (29.9%) or UMIC (25.9%). Patients were discharged home in 83.4% in HIC, 86.1% in UMIC and 92.0% in LLMIC (p<0.0001). Data from 3861 pts showed that 88.8% were alive at the time of the last observation; this rate did not vary by GNI category (p=0.922). Scheduled follow-up for AKI was arranged in only 14% of pts, with non-significant differences among GNI categories (p=0.5)

Conclusions: Pts with AKI had hospital stays that typically exceeded 7 days, although this was less likely in LLMIC. Survival rates did not vary by GNI category. Pts were more likely to be sent home in LLMIC compared to HIC and UMIC; this observation may at least be partially due to the greater prevalence of patients in ICUs 7 days after AKI diagnosis in HIC vs. LLMIC countries. Scheduled follow-up for AKI was infrequent and did not vary by GNI category.

FR-PO458

ISN 0by25 AKI Global Snapshot Project: Indications for Initiating and Withholding Dialysis in AKI Worldwide Etienne Macedo,[1] Ravindra L. Mehta,[2] Giuseppe Remuzzi,[3] Jing Zhang,[2] Melanie Godin,[4] Michael V. Rocco.[5] *[1]U Sao Paulo; [2]U California San Diego; [3]Mario Negri Inst; [4]Sherbrooke U; [5]Wake Forest U.*

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians on pts who had a confirmed diagnosis of AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC). We analyzed the frequency of AKI requiring dialysis and the reasons for starting or withholding dialysis.

Results: Of 3855 pts, 768 (20%) were dialyzed. Mortality rate was significantly different in dialyzed (17%) vs. non-dialyzed (9%) pts (p<0.0001). Among dialyzed pts, the mortality rate was similar in countries of different GNI categories. The main reason to start dialysis was solute control, with a similar distribution among country categories.

Reasons for dialysis	Frequency	Percent	HIC (n=236)	UMIC (n=230)	LLMIC (n=323)	p value
Fluid overload	406	51.5	55.1	50.4	49.5	0.4
Solute control	610	77.3	72.5	73.9	83.3	0.004
Electrolyte or acid/base disturbance	450	57.0	53.8	58.7	58.2	0.49
Intoxication/ poisoning	31	3.9	3.4	8.7	0.9	<0.0001
Other	28	3.5	1.3	5.7	3.7	0.037

Of the non-dialyzed pts (3087), 244 (8%) had a clinical indication but were not dialyzed. Reason for withholding dialysis was different across country levels. In HIC, the main reason to withhold dialysis was futile treatment (79%). In UMIC, main reason was patient cultural beliefs (25%) and in LLMIC financial restriction was as frequent as futile perception (30 and 32%).

Conclusions: Solute control is the most common indication for AKI dialysis around the globe. Lack of resources is a frequent cause of withholding dialysis in LLMIC, while physician perception of futile treatment is the main reason in HIC. Knowledge of local deficits will be important to guide future interventions and to develop strategies to improve outcomes.

FR-PO459

ISN 0by25 AKI Global Snapshot Project: Differences in Location and Process of Care Among AKI Patients Around the Globe

Etienne Macedo,[1] Ravindra L. Mehta,[2] Giuseppe Remuzzi,[3] Jing Zhang,[2] Melanie Godin,[4] Michael V. Rocco.[5] *[1]U Sao Paulo; [2]U California San Diego; [3]Mario Negri Inst; [4]Sherbrooke U; [5]Wake Forest U.*

Background: The Global Snapshot (GSP) was a prospective cross-sectional study designed to capture standardized information on incidence, causes and treatment of AKI in all health care settings throughout countries of diverse economic status.

Methods: A web based survey tool was used to obtain data from pts with a confirmed diagnosis of AKI based on KDIGO criteria in 72 countries. Detailed methodology is found in the ISN GSP abstract on provider characteristics. We analyzed the characteristics of pt location and process of care by gross national income per capita (GNI) country levels. Countries were defined as: Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Based on GNI, 23 countries were classified as LLMIC, 20 as UMIC and 29 as HIC.

	HIC	UMIC	LLMIC
N of patients	1241	1594	1118
Age (adult, yrs)*	67 (55,78)	65 (52,77)	53 (38,65)
% Pediatric (n=343)	13	4	9
Age (peds, yrs)	0.4 (0.03,6.0)	8 (2,16.5)	4 (0.3,13.5)
Location where pts develop AKI **			
Community acquired	51.0	51.1	79.5
Location where patient seen **			
Emergency department	19.5	17.8	16.0
ICU	38.8	26.8	29.5
Ward or stepdown unit	39.1	50.6	47.2
Outpatient clinic	2.7	4.8	7.3
Outcomes			
Dialysis (%)*	63.3	58.3	71.8
Mortality in adults (%)	13.1	13.7	11.9
Mortality in pediatric (%)*	1.2	12.5	19.6
* p < 0.05 **p<0.0001			

Urinalysis was more often performed in LLMIC (86%). More pts in LLMIC were dialyzed (71%). The mortality rate of dialyzed pts and the number of non-renal organ failures present was similar by GNI level. Mortality in community acquired AKI was higher in LLMIC (11%) vs 7% in HIC. LLMIC had higher mortality among ICU pts (21%) vs 13% in HIC (p=0.014). In pediatric pts, mortality was 19.6% in LLMIC compared to 1.2% in HIC (p<0.001).

Conclusions: Community acquired and pediatric AKI had a significantly higher mortality in LLMIC. Although mortality rates of dialyzed and non-dialyzed pts was similar, pts from HIC countries were significantly older. Improvement in risk assessment and early treatment of AKI in areas with fewer resources could lead to improvement in AKI outcomes.

FR-PO460

ISN 0by25 AKI Global Snapshot Project: KDIGO Classification and AKI Diagnosis Around the Globe

Etienne Macedo,[1] Ravindra L. Mehta,[2] Giuseppe Remuzzi,[3] Jing Zhang,[2] Melanie Godin,[4] Michael V. Rocco.[5] *[1]U Sao Paulo; [2]U California San Diego; [3]Mario Negri Inst; [4]Sherbrooke U; [5]Wake Forest U.*

Background: The Global Snapshot (GSP) was a prospective cross-sectional study designed to capture standardized information on incidence, causes and treatment of AKI in all health care settings throughout countries of diverse economic status.

Methods: A web based survey tool was used to obtain data from pts with a confirmed diagnosis of AKI based on serum creatinine (sCr) and urine output (UO) KDIGO criteria in 72 countries. Detailed methodology is found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Of 4024 pts, 2891 (71%) had an available baseline sCr (BsCr), absence was greater in LLMIC (45% vs 18% in HIC, 21% in UMIC). AKI on CKD was seen in 40%. At AKI confirmation day, only 50% of pts had UO volume assessed.

Studies available at AKI diagnosis	HIC (n=1260)	UMIC (n=1605)	LLMIC (n-1153)
Baseline sCr (mg/dl)*	1.04 (0.71,1.60)	1.10 (0.86,1.71)	1.30 (1.00,2.24)
CKD (%)*	26.4	23.4	13.5
sCr at AKI diagnosis (mg/dl)*	2.43 (1.62,4.10)	2.30 (1.53,3.80)	3.26 (2.00,5.80)
UO past 24 hours of AKI diagnosis (ml)*	648 (275,1200)	900(400,1500)	500(200,1000)
sCr (alone) (%)	67.5	79.5	63.9
Oliguria (alone) (%)**	10.5	2.3	7.9
sCr + UO (%)	89.6	97.7	92.1
AKI stage at diagnosis			
1	424(36.7)	644(43.6%)	308(29.5%)
2	192(16.6%)	22(15.4%)	133(12.7%)
3	540(46.7%)	606(41.0%)	605(57.8%)
* p<0.001. **UO criteria by modified KDIGO: Oliguria defined as UO <400 ml or <0.5 ml/kg/hr last 24 h			

In LLMIC, 58% of pts were classified as AKIN stage 3 at AKI diagnosis. sCr was significantly higher in these pts (3.26 mg/dL) compared to 2.43 in pts from HIC and 2.3 in pts from UMIC.

Conclusions: BsCr was often present in pts from HIC and UMIC, where 1/3 of AKI cases occurred in CKD pts. Absence of BsCr was a common issue in LLMIC, associated with higher levels of sCr and KIDGO stage at AKI diagnosis. UO is often not computed in pts who develop AKI. Systematic assessment of urine output in high-risk pts could help identify AKI earlier.

FR-PO461

ISN 0by25 AKI Global Snapshot Project: Risk Factors for AKI

Ravindra L. Mehta,[1] Giuseppe Remuzzi,[2] Jing Zhang,[1] Melanie Godin,[3] Michael V. Rocco,[4] Jorge Cerda,[5] John Feehally,[6] Fredric O. Finkelstein,[7] Nathan W. Levin,[8] Marcello Tonelli.[9] *[1]U California San Diego; [2]Mario Negri Inst; [3]Sherbrooke U; [4]Wake Forest U; [5]Albany Med Coll; [6]U Leicester; [7]Yale U; [8]Renal Research Inst; [9]U Calgary.*

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians about pts who had AKI based on KDIGO criteria. Detailed methodology is found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Participants were distributed from North/East Asia 26.4%, South Asia 18.9%, Latin America/Caribbean 14%, Africa 13.4%, North America 7.3%, Western Europe 6.2%, Oceania/Southeast Asia 4.3%, Russia/Commonwealth Independent States 3.9%, Middle East 3.4%, Eastern/Central Europe 2.2%. Ethnic groups included 53% Asian, 19% Caucasian, 9% Hispanic, 8% African, 7% Middle Eastern and 1.5% Native/Aboriginal. Causes of AKI varied by GNI and were compared by Kruskal-Wallis test.

Risk factors for AKI	Frequency	Percent	HIC	UMIC	LLMIC	p value
Dehydration	1536	38.2	39.1	32.3	45.6	<0.0001
Hypotension/shock	1615	40.2	44.8	38.2	38.2	0.0003
Cardiac	905	22.5	24.3	27.9	13.1	<0.0001
Liver	331	8.2	7.7	9.2	7.5	0.18
Acute kidney disease	488	12.2	11.1	9.4	17.2	<0.0001
Urinary obstruction	320	8.0	7.9	6.9	9.5	0.0421
Infection	1291	32.1	28.8	32.2	35.7	0.0013
Pregnancy related	56	1.4	0.4	0.9	3.1	<0.0001
Systemic diseases	322	8.0	9.4	9.4	4.6	<0.0001
Nephrotoxic agents	980	24.4	29.0	21.7	23.1	<0.0001
Poisoning	73	1.8	2.1	1.4	2.0	0.32
Envenomation			35 0.9 0.3	0.7	1.7	0.0005
Post-surgical	269	6.7	9.2	6.8	3.8	<0.0001

Other organ failures present were pulmonary 16.4% (more common in HIC), cardiovascular 23.1% (less common in LLMIC), neurologic 8.3%, hepatic 10.4%, hematologic 9.5% (more common in LLMIC) and none 53.9%

Conclusions: Hypotension was the most common cause of AKI in HIC and UMIC; dehydration was most common in LLMIC. Acute kidney disease, pregnancy and envenomation were more common in LLMIC.

Funding: Pharmaceutical Company Support - Astute Medical (San Diego, CA, USA), Danone Nutricia Research (Palaiseau, France) and Bellco (Mirandola, Italy)., Private Foundation Support

FR-PO462

ISN 0by25 AKI Global Snapshot Project: Evaluation and Treatment

Jorge Cerda,[1] Ravindra L. Mehta,[2] Giuseppe Remuzzi,[3] Jing Zhang,[2] Melanie Godin,[4] Michael V. Rocco,[5] Emmanuel A. Burdmann,[6] Guillermo Garcia-Garcia,[7] Vivekanand Jha,[8] Andrew J.P. Lewington,[9] Raul Lombardi.[10] *[1]Albany Med Coll; [2]U California San Diego; [3]Mario Negri Inst; [4]Sherbrooke U; [5]Wake Forest U; [6]U Sao Paulo; [7]Hosp Civil de Guadalajara; [8]George Inst Global Health; [9]Leeds Teaching Hosp; [10]Servicio Medico Integral.*

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians about pts who had AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Initial evaluation of AKI included urinalysis in 73.6%, ultrasound in 55% and renal biopsy in 4.1%, with all three more commonly being performed in LLMIC. Initial treatment of AKI included fluids in 74.3%, vasopressors in 23.8%, diuretics in 41.4%, antibiotics in 63.8% and urinary diversion in 19.5%. The receipt of dialytic therapy occurred in 790 of 4018 pts (19.7%), with use in 18.8% in HIC, 14.3% in UMIC and 28.0% in LLMIC. In 244 instances where dialysis was recommended but not performed, futility was cited in 58.6% and cultural beliefs were cited in 25.4%. Unavailability of staff or material resources to perform dialysis was reported in 1.4% of HIC, 3.8% of UMIC and 16.4% of LLMIC. Inability to afford therapy was 1.4% in HIC, 1.9% in UMIC and 16.4% in LLMIC ($p<0.0001$). The ratio of pts not able to receive dialysis by those that did receive dialysis was 0.21 in HIC, 0.25 in UMIC and 0.18 in LLMIC. There were significant differences in the renal modality used.

Treatment (n=790)	Frequency	Percent	HIC	UMIC	LLMIC
IHD	516	65.3	63.3	58.3	71.8
PD	41	5.2	4.6	3.0	7.1
CRRT	157	19.9	31.7	29.1	4.6
UF	10	1.3	2.5	1.7	0
SLED	103	13.0	3.4	10.9	21.7
Other	8	1.0	0.6	1.4	0
Unknown	1	0.1	0	0.2	0

Conclusions: Lack of resources. staff or finances to perform dialysis was most prevalent in LLMIC. When dialysis was provided, it was less likely to be CRRT and more likely to be SLED in LLMIC.

Funding: Pharmaceutical Company Support - Astute Medical (San Diego, CA, USA), Danone Nutricia Research (Palaiseau, France) and Bellco (Mirandola, Italy)., Private Foundation Support

FR-PO463

ISN 0by25 AKI Global Snapshot Project: Provider Characteristics

Melanie Godin,[1] Ravindra L. Mehta,[2] Giuseppe Remuzzi,[3] Jing Zhang,[2] Michael V. Rocco,[4] Jorge Cerda,[5] Vivekanand Jha,[6] Nathan W. Levin,[7] Andrew J.P. Lewington,[8] Etienne Macedo,[9] Marcello Tonelli.[10] *[1]Sherbrooke U; [2]U California San Diego; [3]Mario Negri Inst; [4]Wake Forest U; [5]Albany Med Coll; [6]George Inst Global Health; [7]Renal Research Inst; [8]Leeds Teaching Hosp; [9]U Sao Paulo; [10]U Calgary.*

Background: The ISN 0by25 AKI Global Snapshot Project (GSP) was designed to determine the spectrum of AKI pts seen in health care facilities throughout the world.

Methods: Health care providers joined the GSP after gaining approval from their local IRB. Providers chose one "index" day between 9/29/2014 and 12/7/2014 to provide data on AKI pts under their care. De-identified data on pts who met criteria for AKI by modified KDIGO criteria were entered through a secure website using a standard questionnaire developed by the 0by25 AKI workgroup. Data collected included pt demographics, initial clinical data, diagnostic, treatment and outcome information. Countries were grouped into three categories based on gross national income per capita (GNI); high income with GNI >US$12476, low and lower middle income with GNI <US$4035, and upper middle income with GNI between levels 1 & 3.

Results: 324 surveys from 72 countries were received describing 4024 pts with AKI. Providers included 248 nephrologists, 20 nephrology fellows, 14 intensivists, 26 pediatric nephrologists. Location of facilities by region included 52 from Africa, 47 from Latin America & Caribbean, 45 from North America, 45 from South Asia, 40 from North and East Asia, 34 from Western Europe, 19 from Russia/Commonwealth of Independent States, 17 from Oceania & South East Asia, 14 from Middle East and 11 from Eastern & Central Europe. Size of catchment population for each facility was: >5 million in 28%, 0.5-1.5 million in 26%, 0.1-0.5 million in 19% and 1.5-3 million in 11%. Type of facility was institute in 47%, public hospital or health care concern in 37%, private multispecialty group in 14%. Dialysis was available in 97% of facilities.

Conclusions: This project is the first worldwide point prevalent survey of AKI. It demonstrates the feasibility of obtaining data on AKI using a secure website from practitioners in varied health care settings from six continents.

FR-PO464

Postoperative Acute Kidney Injury in Non-Cardiac Surgery

Seokwoo Park, Dong Ki Kim, Kook-Hwan Oh, Kwon Wook Joo, Yon Su Kim, Hajeong Lee. *Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

Background: Prevention of acute kidney injury (AKI) and amelioration of its severity remain important issues of improving surgical patient outcomes. Therefore, preoperative renal risk evaluation and patient optimization is crucial for nephrologists. Although there are several studies dealing with postoperative AKI in cardiac surgery, they have been seldom studied in non-cardiac surgery.

Methods: We included adult (age ≥ 18 years) patients who received major non-cardiac surgery in Seoul National University Hospital from 2004 to 2013. We extracted their clinical data from our electronic medical record system. Acute Kidney Injury Network criteria (AKIN) was used to define and classify AKI.

Results: Among a total of 95,266 operations, 1,560 cases (1.64%) developed AKI. Patients with AKIN stage I were 964 (1.01%), stage II, 117 (0.12%), and stage III, 479 (0.50%). AKI was most prevalent in urologic surgery, followed by general surgery, orthopedic surgery, and neurologic surgery. Patients who developed AKI tended to be older (53.7 vs. 58.9 years), and male (45.6% vs. 65.6%). Patients with AKI had higher prevalence of underlying diseases such as liver/heart/hematologic/vascular and neurologic disease than those without. Moreover, they showed higher baseline systolic blood pressure and lower baseline diastolic blood pressure than those without. Baseline renal function was lower in AKI-developed patients than the others (0.90 vs. 1.13 mg/dL, P <0.001). Multivariate logistic regression analyses found that older age, male sex, lower baseline renal function, presence of hypertension, longer duration of surgical time and orthopedic or urologic surgery were significant risk factors for postoperative AKI in noncardiac surgery.

Conclusions: In this study, we demonstrated the incidence of postoperative AKI in non-cardiac major operations. Moreover, we found clinical risk factors for postoperative AKI development. Further investigation of prediction models for postoperative AKI in major non-cardiac surgery should be warranted for development of preoperative renal optimization strategy.

FR-PO465

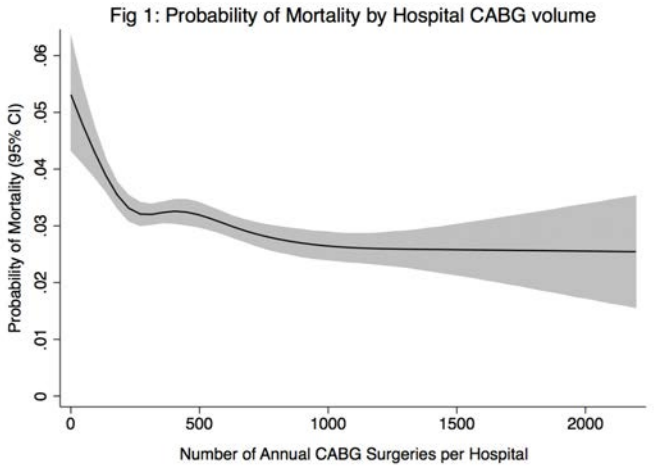
Impact of Hospital CABG Volume and AKI Needing Dialysis on CABG Hospitalizations

Ankit Sakhuja,[1] Jesse D. Schold,[2] Edward G. Soltesz,[3] Sevag Demirjian.[2] *[1]Div of Nephrology, Univ of Michigan; [2]Nephrology and Hypertension, Cleveland Clinic; [3]Thoracic and Cardiovascular Surgery, Cleveland Clinic.*

Background: Acute Kidney Injury (AKI) is common after Coronary Artery Bypass Grafting (CABG) and associated with poor outcome. Increased hospital procedure volume has been associated with better outcomes. We examined (1) impact of number of annual CABG procedures per hospital (CABG-vol) on AKI needing dialysis (AKI-D) and mortality, and (2) if it modifies the relationship between AKI-D and mortality.

Methods: Using Nationwide Inpatient Sample database from 2000-2010 we identified admissions with CABG using ICD-9-CM codes. Those with AKI-D were identified and those with kidney transplant or on maintenance dialysis were excluded. Multivariable logistic regressions were used to assess impact of CABG-vol on AKI-D and mortality. We used restricted cubic splines to account for non-linear relationship between CABG-vol and mortality. A priori interaction term between CABG-vol & AKI-D was assessed in model for mortality.

Results: Of estimated 3,337,292 (95% CI: 3,103,610-3.570,973) hospitalizations for CABG, 0.7% (24,126) had AKI-D. Those with AKI-D were older, more females (37.5% vs 29.1%; $p<0.001$) and blacks (7.4% vs 5.5%; $p<0.001$). On adjusted analysis, CABG-vol was not correlated with odds of developing AKI-D (0.99; 95% CI 0.99-1.00) but was associated with mortality (Fig 1).



AKI-D was a significant predictor of mortality with OR 13.75 (95% CI: 11.37-16.64). Interaction term between CABG-vol & AKI-D was not significant (p=0.8).

Conclusions: Lower annual CABG hospital procedure volume is significantly associated with higher mortality but not with higher incidence of AKI-D. AKI-D is associated with higher mortality in those undergoing CABG, however, there is no differential effect of hospital volume on adjusted odds of mortality due to AKI-D.

FR-PO466

Five-Year Risk of Renal Outcomes After Pediatric Cardiac Surgery

Jason Henry Greenberg,[1] Michael Zappitelli,[2] Heather Thiessen Philbrook,[1] Prasad Devarajan,[3] Catherine Krawczeski,[3] Steven G. Coca,[1] Chirag R. Parikh.[1] *[1]Program of Applied Translational Research, Yale School of Medicine; [2]Dept of Pediatrics, McGill Health Centre; [3]Dept of Pediatrics, Cincinnati Children's Medical Center.*

Background: Pediatric cardiac surgery is associated with a high risk of acute kidney injury(AKI) and other short-term adverse outcomes. However, the risk for long-term renal outcomes after cardiac surgery is unknown.

Methods: We performed 5 year follow-up on the Translational Research Investigating Biomarker Endpoints in AKI(TRIBE-AKI) cohort. TRIBE-AKI is a three-center prospective cohort study of children 1 month to 18 years old who underwent cardiopulmonary bypass.

Results: Out of 305 children who survived their index hospitalization, 4(1.3%) died after discharge and 128(42%) participated in the 5 year follow-up. Mean age of the cohort at follow-up was 9.2 years and 53% were male. 56 out of 128 patients had perioperative AKI defined as a post-operative serum creatinine rise by 50% or 0.3mg/dL from pre-operative baseline. At a median of 5.4 years of follow-up, hypertension, microalbuminuria, eGFR<90, and eGFR<60 were identified in 13%, 6.3%, 7.0%, and 0.8% of patients, respectively. CKD, defined as eGFR<90 or microalbuminuria, was present in 13% of children. There were no significant differences in renal outcomes between patients with and without perioperative AKI. 5(4.0%) patients had been seen by a pediatric nephrologist. The 5-year post-operative prevalence of hypertension in our cohort was >8 fold higher than found in the general pediatric population(Table).

Conclusions: Overall, there is a high prevalence of CKD and hypertension in children 5 years after cardiac surgery. Despite this high prevalence of CKD, very few children were seeing a pediatric nephrologist. These findings may have implications for renal care and late cardiovascular disease in children after cardiac surgery.

	Definition	TRIBE-AKI 5 Year Follow-up	General pediatric population
Hypertension	BP>95th percentile	13%(CI 7.8-19%)	1.6%(CI 1.0-2.4%)
Microalbuminuria	Albumin/ Creatinine>30mg/g	6.3%(CI 3.2-12%)	9.9%
eGFR<90	Bedside CKID formula	7.0%(CI 3.7-13%)	Not available
CKD	eGFR<90 or albuminuria	13.3%(CI 8.5-20%)	Not available

Funding: NIDDK Support

FR-PO467

Changes of Epidemiology and Influencing Factors of Acute Kidney Injury After Cardiac Surgery – A Five-Year Study from 2009 to 2013

Zhouping Zou,[1,2] Jiarui Xu,[1,2] Wenlv Lv,[1,2] Bo Shen,[1,2] Yi Fang,[1,3] Jianzhou Zou,[1,2] Jie Teng,[1,2] Xiaoqiang Ding.[1,2,3] *[1]Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; [2]Shanghai Inst for Kidney and Dialysis, Zhongshan Hospital, Fudan Univ, Shanghai, China; [3]Shanghai Key Laboratory of Kidney Disease and Blood Purification, Zhongshan Hospital, Fudan Univ, Shanghai, China.*

Background: Cardiac Surgery is a common cause of acute kidney injury (AKI). We collected the epidemiological data of patients with AKI from 2009 to 2013 in order to explore the influencing factors of changes of epidemiology after cardiac surgery.

Methods: Clinical data of patients undergoing cardiac surgery,which included demographic data of preoperative,intraoperative,postoperative were prospectively collected in our hospital from January 2009 to December 2013. The main endpoint was poor prognosis which included overall mortality and abandom of treatment. The second point was renal outcome.

Results: A total of 11693 patients enrolled, including 6637 males and 5056 females. The overall AKI incidence was 34.5%(n=4030). The AKI incidence increased during the five years from 34.2% to 36.5% (P<0.05) .There was no significantly statistical differences in AKI-RRT incidences during the five years (p=0.360); The hospital mortality of AKI decreased from 6.3% in 2009 to 3.8% in 2013. The incidence of poor prognosis in AKI were 8.3%,7.5%,6.8% ,5.1%,8.0% (P=0.196).The mortality of AKI-RRT decreased from 47.1% to 29.5%, but there was no statistical difference (P = 0.230). The incidence of poor prognosis in RRT decreased from 66.7% to 57.4%, also no significantly statistical difference (P =0.825).Multivariate logistic regression analysis showed that male,age(every additional 10 years),body mass index(every additional 5kg/m^2),hypertension,chronic heart failure,pre-operative serum creatinine >115mmol/L,CPB(every additional 30min) were the risk factors of AKI after cardiac surgery.

Conclusions: The incidence of AKI after cardiac surgery increased from 2009 to 2013 and the rate of poor prognosis did not change. The incidence of AKI-RRT and the rate of poor prognosis remained high. The prevention and treatment of AKI still need improvement.

Funding: Government Support - Non-U.S.

FR-PO468

The Very Long-Term Co-Morbidity Adjusted Impact of AKI following Cardiac Surgery: A 15-Year Follow-Up Study

Alejandro Ferreiro,[1] Raul Lombardi.[2] *[1]Nephrology, INCC. Facultad de Medicina, Montevideo, Uruguay; [2]Critical Care Medicine, SMI, Montevideo, Uruguay.*

Background: AKI is a frequent complication of cardiac surgery (CS) associated to high mortality. The co-morbidity adjusted residual impact on very long-term mortality (> 12 year) of AKI, excluding the initial catastrophic impact on early mortality has never been addressed before. **Objectives:** to evaluate the net attributable impact of AKI after CS on long-term mortality.

Methods: All adult patients submitted to CS between 1/1/2000 and 31/12/2013 (n=7755) were enrolled. The INCC prospective-collected database with more than 750 variables (demographics, comorbidities, type of CS, intraoperative and postoperative variables, peri-operative support and short time outcomes) was used. Long-term survival (up to 15 year by December 2014) was obtained by systematic telephone survey (minimum 1-year follow-up) and the National Population Registry. AKI stages were defined according to KDIGO definition. Demographics, logistic EuroSCORE (and their single components), type of CS, baseline renal function (Cockroft-Gault formula) were used for comorbidity risk-adjustment. Statistical analysis: "t"test, c^2 test, Kruskal-Wallis test, Kaplan-Meier curves with long-rank test and Cox regression for multivariate survival analysis. Only patients alive after the first 1 year follow-up entered in the long-term survival analysis (n= 6956).

Results: AKI incidence: 38.4%. RRT: 1.7%. Long-term (15 years) actuarial survival after 1 year follow-up: no AKI 0.58; AKI (I): 0.47; AKI (II): 0.39; AKI (III): 0.27 (p<0.001). In multivariate Cox regression analysis, AKI stages I, II and III (OR 1.17; 1.24; 1.62 respectively) were independently associated with mortality between 1 year after CS and 15 year follow-up, even after adjustment with logistic EuroSCORE (OR 1.02), age (OR 1.038), diabetes (OR 1.58), pre operative *e*GFR (OR 0.996) and no-isolated coronary bypass surgery (OR 1.24).

Conclusions: AKI and its severity are independently associated with very long-term mortality, even after discarding short term events (1 year), in cardiac surgery. Should AKI be causative or a surrogate marker of late events in the long term follow up is a matter of concern to be evaluated.

FR-PO469

Incidence and Influencing Factors of Cardiac Surgery-Associated Acute Kidney Injury Based on the KDIGO Criteria: A Retrospective Cohort Study

Changchun Cao,[1] Xiangcheng Xie,[1] Xin Wan.[1] *[1]Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital); [2]Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital); [3]Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital).*

Background: The incidence and influencing factors of cardiac surgery-associated acute kidney injury (CSA-AKI) based on the KDIGO criteria have not been well studied. This study was aimed to evaluate the incidence, risk or protective factors of acute kidney injury (AKI) in patients after cardiac surgery.

Methods: A retrospective analysis of 2575 patients undergoing first documented cardiac surgery with cardiopulmonary bypass (CPB) between January 2008 and December 2012 in our hospital was conducted. Perioperative variables were collected and analyzed. Univariate and multiple logistic regression models were used for determining the association between the development of AKI and risk factors.

Results: Of 2575 patients, 931 (36%) developed AKI. A total of 30(1.2%) patients required renal replacement therapy. The overall in-hospital mortality rate was 1.5% (38 of 2575). CSA-AKI was significantly associated with in-hospital mortality (adjusted HR: 2.22, 95% CI 1.16-4.24, P = 0.016), especially in patients needing RRT (adjusted HR: 18.68, 95% CI 8.58-40.68, P < 0.001). The independent risk factors identified by multivariate analysis were shown in **[table 1].**

Variable	Odds ratio	95 % CI	P
Male	1.14	1.17-1.71	<0.001
BMI	1.29	1.11-1.49	0.001
History of hypertension	1.49	1.21-1.84	<0.001
Insulin-controlled diabetes	1.56	1.06-2.30	0.025
Creatinine (>88.4μmol/L)	1.88	0.94-3.72	0.074
Red blood cells transfused(U)	1.08	1.05-1.11	<0.001
CPB duration ≥110min	1.31	1.07-1.61	0.009
Mechanical ventilation≥9h	1.45	1.20-1.75	<0.001
Ulinastatin administration	0.69	0.56-0.88	0.006
Body temperature (>38°C) after surgery within 3 days	1.23	1.02-1.50	0.032

Conclusions: This study demonstrates that mechanical ventilation duration, erythrocytes transfusion and postoperative body temperature above 38°C within 3 days were considered independent risk factors for CSA-AKI. Use of ulinastatin was associated with lower incidence of CSA-AKI.

Funding: Government Support - Non-U.S.

FR-PO470

Acute Kidney Injury Post-Major Orthopaedic Surgery: A Single Centre Experience

Tracey Ying,[1] Samantha Chan,[1] Stephen E. Lane,[2,3] Christine A. Somerville.[1] *[1]Dept of Renal Medicine, Univ Hospital Geelong, Geelong, Victoria, Australia; [2]Barwon Health Biostatistics Unit, Univ Hospital Geelong, Geelong, Victoria, Australia; [3]School of Medicine, Deakin Univ, Geelong, Victoria, Australia.*

Background: Given the increasing incidence of AKI and the burden this places on the medical system, there is a clear need to expand the practise of 'preventative nephrology' – the optimisation of renal function through minimisation of potential insults. Renoprotection is particularly critical in the perioperative setting, a period of high renal vulnerability. However, there is currently little evidence regarding numerous theoretical risk factors for postoperative AKI.

Methods: All patients undergoing MOS at our centre between 2008 and 2014 were included. Out of 2227 surgeries audited for AKI using comparisons of preoperative and postoperative creatinine, 164 cases were identified (per RIFLE criteria) and matched to controls 2:1 for age, sex, procedure and chronic kidney disease stage. Their records were reviewed for established and proposed risk factors for postoperative AKI: diuretic, non-steroidal anti-inflammatory (NSAID) and angiotensin-converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) use. Associations of proven and hypothetical risk factors were estimated using conditional logistic regression.

Results: Controlling for known risk factors, both diuretic and ACEi or ARB use were found to be associated with an approximately twofold increased risk of AKI (diuretic – OR 2.06 95%CI:1.30-3.26, p<0.005, ACEi/ARB – OR 2.09 95%CI:1.31-3.32, p<0.005). A dose-effect model accounting for preoperative, intraoperative and postoperative NSAID administration demonstrated a linear relationship between the number of times NSAIDs were given and postoperative AKI risk (OR 1.35 95%CI:1.05-1.73, p<0.05).

Conclusions: Perioperative diuretic, NSAID and ACEi or ARB use were shown to be significantly associated with postoperative AKI, indicating that these medications should be used with caution in MOS. Further prospective studies are required to confirm this.

FR-PO471

Incidence of In-Hospital Acute Kidney Injury by Surgery and Invasive Surgical Procedures Among Non-Emergency Hospital Admissions

Joshua Taylor Swan,[1,2] Beverly A. Shirkey,[1] Linda W. Moore,[1] Wadi N. Suki,[1] A. Osama Gaber.[1,3] *[1]Houston Methodist Hospital; [2]Texas Southern Univ; [3]Weil Cornell Medical College.*

Background: This study aimed to identify non-emergency invasive surgical procedures that are associated with the highest burden of in-hospital AKI.

Methods: Urgent and elective admissions to a quaternary teaching hospital in 2012-2013 with a principal procedure within 1 day of admission were included. Principal procedures were categorized using AHRQ's Clinical Classifications Software (CCS). Patients <18 years, nephrectomy, and those with preexisting AKI or stage 5 CKD were excluded. AKI was defined as an increase in SCr by >=0.3 mg/dL or >=50% over a 72-hour interval, staged per KDIGO.

Results: AKI occurred during 18% (2,244) of 12,237 admissions. Of AKI cases, 82% (1,828) were stage 1, 12% (273) stage 2, and 6% (143) stage 3. Patients were 69% white, 51% female, aged 61±16, and 9% with CKD. Ten CCS groups with the largest number of AKI cases are presented.

CCS Category, CCS code	Admissions, n	Any AKI, n (%)	Stage 1 AKI, n (%)	Stage 2 AKI, n (%)	Stage 3 AKI, n (%)
Organ transplantation (other than bone marrow, corneal or kidney), 176	234	161 (69)	92 (39)	42 (18)	27 (12)
Heart valve procedures, 43	713	323 (45)	263 (37)	47 (7)	13 (2)
Coronary artery bypass graft (CABG), 44	403	176 (44)	152 (38)	19 (5)	5 (1)
Diagnostic bronchoscopy and biopsy of bronchus, 37	248	73 (29)	65 (26)	5 (2)	3 (1)
Other OR heart procedures, 49	251	59 (24)	46 (18)	10 (4)	3 (1)
Other OR procedures on vessels other than head and neck, 61	286	64 (22)	54 (19)	3 (1)	7 (2)
Diagnostic cardiac catheterization; coronary arteriography, 47	300	52 (17)	46 (15)	4 (1)	2 (1)
Colorectal resection, 78	439	57 (13)	44 (10)	7 (2)	6 (1)
Arthroplasty knee, 152	1100	126 (11)	113 (10)	7 (1)	6 (1)
Hip replacement; total and partial, 153	873	99 (11)	89 (10)	7 (1)	3 (0)

Conclusions: This study presents the incidence of AKI after invasive surgical principal procedures, and this data will help prioritize research to prevent in-hospital AKI. Non-kidney transplant, heart valve, and CABG surgical procedures were associated with the largest number of AKI cases at this single center, and non-kidney organ transplants were associated with a high severity of AKI.

FR-PO472

Acute Kidney Injury following Gastrointestinal Surgery

Þórir E. Long,[1,4] Dadi Helgason,[1] Sólveig Helgadóttir,[2,4] Tomas Gudbjartsson,[3,4] Gisli H. Sigurdsson,[2,4] Martin I. Sigurdsson,[2,5] Olafur S. Indridason.[6] *[1]Dept of Medicine; [2]Dept of Anesthesia; [3]Dept of Cardiothoracic Surgery, Landspitali; [4]Faculty of Medicine, Univ of Iceland; [5]Dept of Anesthesia, Brigham and Women's Hospital, Boston, MA; [6]Div of Nephrology, Landspitali - The National Univ Hospital, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) is a serious postsurgical complication but AKI after nonvascular abdominal surgery has not been thoroughly studied. The aim of this study was to examine the incidence of AKI after such operations, its risk factors and survival of patients.

Methods: We studied all nonvascular abdominal operations performed on adults 2007-2014 at Landspitali, the major hospital in Iceland. AKI was diagnosed according to the creatinine based KDIGO criteria. Risk factors for AKI were evaluated using logistic regression analysis. Survival was compared between AKI and non-AKI patients using Kaplan-Meier method after propensity score matching (1:1, nearest neighbor matching).

Results: A total of 10,022 patients underwent 11,552 operations during the study period, 38.0% were acute operations. Median age at operation was 52 yrs (IQR 32-66) and 59.5% of patients were female. AKI occurred after 246 operations (2.1%), with 157 (1.4%), 57 (0.5%) and 32 (0.3%) of stage 1, 2 and 3, respectively. Incidence of AKI was higher after major (5.3%), open (4.9%) and acute operations (3.0%) compared to minor (1.1%), laparoscopic (0.5%) and non-acute operations (1.8%). In multivariable analysis, postoperative AKI associated with age (OR 1.03 (95%CI (1.04-1.04)), male sex 1.5 (1.1 – 2.0), open operation 3.0 (2.2-4.2), re-operation 4.8 (3.7-8.6), hypertension 1.7 (1.2-2.4), eGFR <60ml/min/1.73 m^2 2.0 (1.4-2.7) and ASA score 6.1 (4.2-8.8). Survival was worse for AKI patients compared to the propensity score matched contros, both at 30 days (82.4% vs, 94.7%, p=0.03) and at 1-year (69.9% vs. 82.6%, p=0.03).

Conclusions: The incidence of AKI is relatively low after gastrointestinal surgery compared to cardiac and vascular surgery. The rate of AKI is substantially higher after major and open operations and in patients with preexisting kidney disease. AKI is associated with increased short- and long-term mortality.

FR-PO473

Risk Factors Associated with Post-Operative AKI After General Surgery

Pradeep Arora,[1] Leili Pourafkari,[2] James W. Lohr,[1] Hasan H. Dosluoglu,[3] Nader Nader.[1] *[1]Div of Nephrology, VAMC, Buffalo, NY; [2]Anesthesiology, VAMC, Buffalo, NY; [3]Surgery, VAMC, Buffalo, NY.*

Background: AKI after cardiac and vascular surgery has been extensively studied. However there is no study which has evaluated the factors associated with development of stage 1 AKI by AKIN criteria in general surgery patients.

Methods: We conducted a cohort study using a prospective database of patients undergoing surgical procedures since 2000 in the VA Western New York Healthcare System which are in part reported to the National Surgical Quality Improvement Program (NSQIP). Demographic, social history, co-morbid diseases, including coronary artery disease (CAD), congestive heart failure (CHF), chronic obstructive lung disease (COPD), peripheral vascular disease (PVD), cerebrovascular accidents (CVA), hypertension, and diabetes, were prospectively entered into the Veterans Affairs Surgical Quality Improvement Program (VASQIP) database at the time of surgery. Preoperative laboratory data were also entered for each participant. Univariate and multivariate logistic regression were performed to estimate the odds of AKI after surgery.

Results: A total of 13300 patients who underwent non-cardiac and non-vascular surgery whose data was available to define AKI between 2000-2014 were included in this analysis. A total of 1621 patients developed AKI stage 1. In univariate analysis, increasing age, male gender, ASA class, poor functional status, presence of COPD, Ascites, CVA, CVD, DM, CHF, HTN, preop coronary intervention or MI, HCT <24, Low serum albumin, increased operating room (OR) time and blood transfusions were associated with increased odds of AKI. Results of multivariate analysis are shown in table 1.

Variable	Odds ratio with 95% CI
Age	1.02 (1.02-1.03)
CHF	1.22 (1.03-1.47)
COPD	1.11 (1.02-1.21)
DM	1.21 (1.12-1.32)
OR time	1.15 (1.10-1.20)
Pre creatinine	1.21(1.08- 1.36)
HCT <24	1.75(1.59-1.92)
Transfusion during surgery	1.34 (1.07-1.69)
Serum albumin	0.72 (0.62-0.81)

Conclusions: AKI is associated with increased length of hospital stay and mortality. Efforts to recognize and intervene in preoperative modifiable factors to prevent AKI will improve outcomes in general surgical patients.

FR-PO474

The Comparison of the Incidence of Acute Kidney Injury Post Coronary Artery Bypass Graft versus Percutaneous Coronary Intervention: National Inpatient Sample Experience Wen Shen, Fernando Rodrigo Aguilar, Alex Montero. *Divsion of Nephrology & Hypertension, Georgetown Univ, Washington, DC.*

Background: AKI, a common complication after coronary revascularization, is associated with increased risk of short-term and long-term mortality, and renal loss. Although survival benefit of CABG over PCI was shown in patients with diabetes and congestive heart failure, the incidence of AKI post coronary revascularization needs to be considered when comparing the risks and benefits of CABG vs PCI.

Methods: We extracted total 485742 cases from National Inpatient Sample (NIS) to create a propensity-score matched cohort of patients who had multivessel coronary disease and underwent first-time CABG or PCI between 2004-2012. Patients received concomitant valvular repair or both CABG and PCI on same admission, history of organ transplant, CKD stage IV or ESRD on dialysis were excluded. Both groups were matched for age, gender, race, payer, prior MI, unstable angina, heart failure, CVA, stroke or TIA, peripheral arterial disease, mitral or aortic valve disease, atrial flutter/fibrillation, ventricular fibrillation or tachycardia, CKD, diabetes, HTN, dyslipidemia, smoking, cirrhosis, obesity, anemia and in-hospital GI bleeding. The odds ratios were estimated by logistic regression analysis.

Results: The incidence of AKI in CABG group was higher than PCI group (8.41% vs 4.00%, OR 2.20, 95% CI 2.15-2.25, P< 0.001). The incidences of severe AKI requiring RRT were similar in both groups (0.95% vs 0.91%, P=0.147). Compared with PCI group, CABG group had higher total in-hospital mortality (1.99% vs 1.48%, OR 1.34, 95% CI 1.24-1.40, P<0.0001).The in-hospital mortality in patients with AKI was higher in CABG (0.92% vs 0.59%, P<0.0001).

Conclusions: Patients received CABG were at higher risk of developing AKI and associated with higher total in-hospital mortality. The in-hospital mortality in patients with AKI was higher in CABG.

FR-PO475

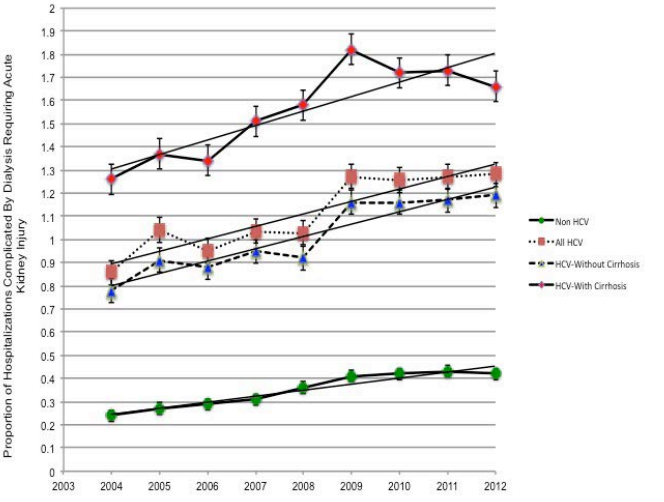
Dialysis-Requiring Acute Kidney Injury Among Hospitalized Adults with Documented Hepatitis C Virus Infection: A Nationwide Inpatient Sample Analysis Girish N. Nadkarni,[1] Achint Patel,[1] Priya Simoes,[1] Rabi Yacoub,[1] Narender Annapureddy,[2] Sunil Kamat,[3] Ioannis Konstantinidis,[1] Ponni Perumalswami,[1] Andrea D. Branch,[1] Steven G. Coca,[1] Christina M. Wyatt.[1] *[1]Mount Sinai Medicine; [2]Vanderbilt Univ; [3]Kokilaben Dhirubhai Ambani Hospital and Medical Research Inst.*

Background: Chronic Hepatitis C virus (HCV) infection causes kidney injury,; data on acute kidney injury (AKI) epidemiology in HCV are limited. We aimed to describe national temporal trends of severe AKI requiring dialysis ("AKI-D") in hospitalized adults with HCV.

Methods: We extracted our study cohort from the Nationwide Inpatient Sample (NIS) of the Healthcare Cost and Utilization Project using data from 2004-2012. We defined HCV and AKI-D based on previously validated ICD-9-CM codes. We analyzed temporal changes in proportion of hospitalizations complicated by AKI-D and utilized survey multivariable logistic regression models to estimate its impact on in-hospital mortality.

Results: We identified a total of 4,603,718 adult hospitalizations with associated HCV from 2004-2012, of which 51,434 (1.12%) were complicated by AKI-D. The proportion complicated by AKI-D increased significantly from 0.86% in 2004 to 1.28% in 2012. Trend was similar when stratified by cirrhosis and paralleled that in HCV negative hospitalizations.

Figure 1. Temporal Trends in the Incidence of Acute Kidney Injury (AKI) Requiring Renal Replacement Therapy among Hospitalized Adults with and without Documented Hepatitis C Virus Infection



In-hospital mortality was significantly higher in hospitalizations complicated by AKI-D vs. those without (27.38% vs. 2.95%; adjusted odds ratio 2.09, 95% Confidence Interval 1.74-2.51) which remained stable over the study period.

Conclusions: The proportion of HCV hospitalizations complicated by AKI-D increased significantly between 2004-2012. Similar to observations in the general population, AKI-D was associated with two-fold increase in odds of in-hospital mortality. These results highlight the burden of severe AKI in hospitalized adults with HCV infection.

FR-PO476

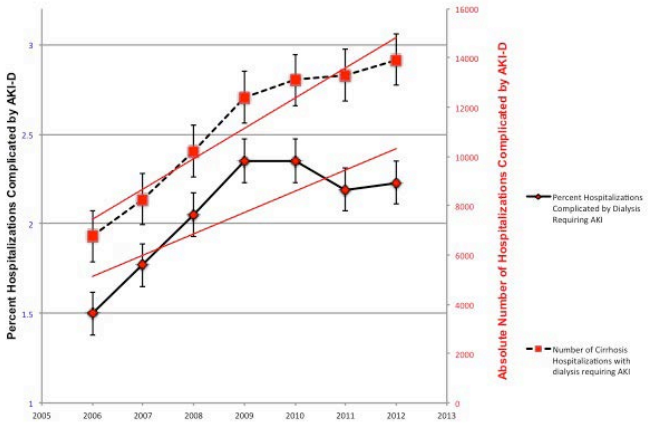
The Burden of Dialysis Requiring Acute Kidney Injury in Decompensated Cirrhosis: A Nationwide Inpatient Sample Analysis Girish N. Nadkarni,[1] Achint Patel,[1] Priya Simoes,[1] Rabi Yacoub,[1] Ioannis Konstantinidis,[1] Sunil Kamat,[3] Narender Annapureddy,[2] Chirag R. Parikh,[4] Steven G. Coca.[1] *[1]Mount Sinai Medicine; [2]Vanderbilt Univ; [3]Kokilaben Dhirubhai Ambani Hospital; [4]Yale Univ.*

Background: Cirrhosis affects nearly 5.5 million patients with an estimated cost of 4 billion. Previous studies about dialysis requiring acute kidney injury (AKI-D) in decompensated cirrhosis (DC) are from a single center or year. We aimed to describe national trends of incidence & impact of AKI-D in DC hospitalizations.

Methods: We extracted our cohort from Nationwide Inpatient Sample (NIS) from 2006-2012. We identified hospitalizations with DC & AKI-D by validated ICD9 codes. We analyzed temporal changes in proportion of DC hospitalizations complicated by AKI-D & utilized multivariable logistic regression models to estimate AKI-D impact on in-hospital mortality.

Results: We identified a total of 36,55,700 adult DC hospitalizations from 2006-2012 of which 78,015 (2.1%) had AKI-D. Proportion with AKI-D increased from 1.5% in 2006 to 2.23% in 2012; this was stable between 2009-12 despite increase in absolute number from 6773 to 13930.

Figure 1: Temporal Trends of Proportion and Absolute Number of Decompensated Cirrhosis Hospitalizations Complicated by Dialysis Requiring Acute Kidney Injury



The overall hospital mortality was significantly higher in hospitalizations with AKI-D vs. those without (40.87% vs. 6.96%; p<0.001). After adjusting for demographics, mortality risk ,acute/chronic comorbidities & hospital level factors, the adjusted odds ratio for mortality was 2.17(95% CI 2.06-2.28;p<0.01) with AKI-D, which was stable from 2006-2012.

Conclusions: The proportion of DC hospitalizations with AKI-D increased from 2006-09 & although, this was stable from 2009-12, there was an increase in absolute case number. These results elucidate burden of AKI-D on DC hospitalizations & excess associated mortality as well as highlight the importance of prevention, early diagnosis & testing of novel interventions in this vulnerable population.

Funding: NIDDK Support

FR-PO477

Temporal Trends of Burden of Dialysis Requiring Acute Kidney Injury in Cerebrovascular Accident Hospitalizations

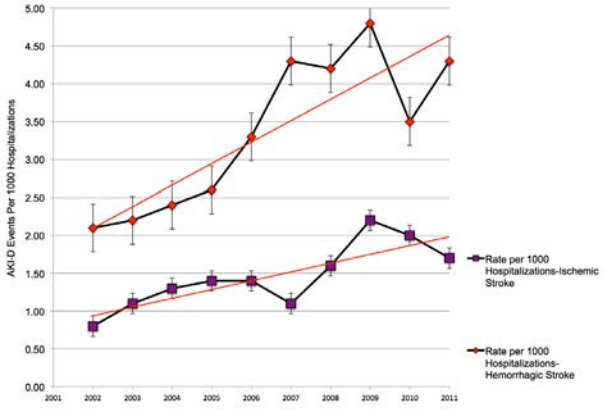
Girish N. Nadkarni,[1] Achint Patel,[1] Abhimanyu Mahajan,[2] Ioannis Konstantinidis,[1] Yuri Ahuja,[3] Rabi Yacoub,[1] Charuhas V. Thakar.[4] *[1]Icahn School of Medicine at Mount Sinai; [2]Henry Ford Hospital; [3]Yale Univ; [4]Univ of Cincinnati & Cincinnati VA Medical Center.*

Background: The epidemiology of dialysis requiring acute kidney injury (AKI-D) in acute ischemic stroke(AIS) and intracerebral hemorrhage(ICH) admissions is poorly understood with previous studies being from a single center and/or year.

Methods: We used the Nationwide Inpatient Sample to evaluate the yearly incidence trends of AKI-D in AIS and ICH admissions from 2002 to 2011. We also evaluated the trend of impact of AKI-D on in-hospital mortality and adverse discharge utilizing adjusted odds ratios (aOR) after adjusting for demographics and comorbidity indices.

Results: We extracted a total of 3927267 AIS and 704648 ICH admissions, AKI-D occurred in 1.5 and 3.5 per 1000 in AIS and ICH admissions respectively. Incidence of admissions complicated by AKI-D doubled from 0.9/1000 to 0.1.7/1000 in AIS and from 2.1/1000 to 4.3/1000 in ICH admissions.

Figure 1: Temporal Trends of Proportion of AIS/ICH hospitalizations complicated by AKI-D



In AIS admissions, AKI-D was associated with 30% higher odds of mortality (aOR 1.30; 95% CI 1.12-1.48;p<0.001) and 18% higher odds of adverse discharge (aOR 1.18; 95% CI 1.02-1.37;p<0.001). Similarly, in ICH admissions, dAKI was associated with twice the odds of mortality (aOR 1.95; 95% CI 1.61-2.36;p<0.01) and 74% higher odds of adverse discharge (aOR 1.74; 95% CI 1.34-2.24;p<0.01).

Conclusions: Incidence of dAKI complicating CVA hospitalizations continues to grow and is associated with increased mortality and adverse discharge. This highlights the need for early diagnosis and better risk stratification in this vulnerable population.

FR-PO478

Long-Term Healthcare Utilization and Mortality After Acute Kidney Injury in Critically Ill Children

Erin Hessey,[1] Genevieve Morissette,[2] Rami Ali,[2] Marc Dorais,[3] Philippe Jouvet,[2] Ana Palijan,[1] Veronique Phan,[2] Michael Pizzi,[1] Michael Zappitelli.[1] *[1]McGill U, Montreal; [2]U de Montreal, Montreal; [3]StatScience, NDIP, Canada.*

Background: Acute kidney injury (AKI) is common in the pediatric intensive care unit (PICU). The late illness burden of child AKI is unknown. We will evaluate if AKI in the PICU is associated with increased mortality and health care service use 5 years after discharge.

Methods: Retrospective cohort study of children admitted to two Montreal, Canada PICUs, 2003-2005 (N=2500). Exclusions: no health number, deceased in PICU. Clinical chart data was merged with provincial administrative health data. AKI (main exposure): by Kidney Disease Improving Global Outcomes serum creatinine (SCr) definition (if no PICU-SCr drawn, non-AKI was assumed). 5-year outcomes: all-cause mortality; healthcare utilization (HCU), defined as the number of hospitalizations, emergency room (ER) and physician visits per 100 person years. AKI-outcome relation was evaluated with multivariate logistic (mortality) and linear regression (HCU), adjusting for gender, age, cardiac surgery, PRISM (mortality) score, vasopressors and infection.

Results: Of 2407 children (mean±SD age=6.0±5.7yrs; PRISM = 8.2±5.9); 56% male; 448 (18.6%) developed AKI. AKI (yes/no) was associated with mortality in univariate (p<0.05) but not multivariate analysis. Stage 2 AKI or worse was associated with 5-year mortality (adjusted[adj]OR=1.9, 95% CI= 1.1-3.2). AKI (yes/no) was associated with increased 5-year hospitalizations (adj p<0.05) and physician visits (adj p<0.001), but not ER visits (adj p=0.8). There was a graded increase in 5-year HCU with higher AKI severity.

Figure 1: Association of increasing AKI severity with number of hospitalizations, ER visits and physician visits in the long-term. Box plots. Middle line = median; Upper and lower edges = 75% and 25%, respectively; Bars = 1.5 x IQR (Interquartile range).

Figure 1A Hospitalizations and ER visits.

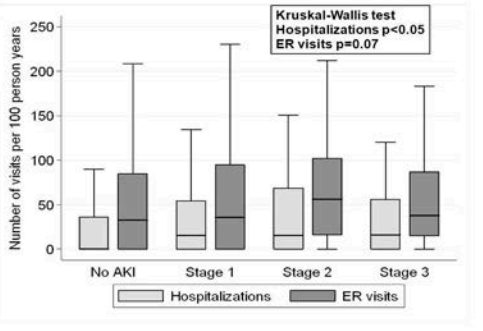


Figure 1B Physician visits.

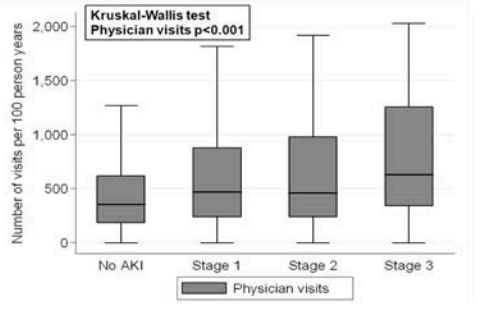


Conclusions: PICU-AKI is associated with long-term increased mortality risk and HCU. Research should evaluate cost-effective interventions to improve child AKI treatment and evaluate effects on late outcomes.

Funding: Government Support - Non-U.S.

FR-PO479

Acute Kidney Injury: A 12 Month Follow, the Incidence and Mortality

Hsu pheen Chong, Paul R. Cannon, Caroline J. Whyte, Kottarathil Abraham Abraham. *Nephrology, Aintree Univ Hospital, United Kingdom.*

Background: Acute Kidney Injury (AKI) affects nearly 1 in 5 hospital admission. It carries a poor prognosis with mortality ranging from 10-80% dependent on the population studied. Aintree University Hospital caters to about a population of 506,000 in North Liverpool. An observational study was carried out in this catchment area to ascertain the incidence of AKI, the length of stay and its effect on 12 months mortality.

Methods: Patients who were admitted between the time periods of August 2012 until January 2013 were included in this study. Liaising with the biochemistry department, all patients who had a rise in their creatinine based on the Acute Kidney Injury Network Criteria received an e-alert sign on the computer system. Clinical outcomes were obtained from each patient record.

Results: There were a total of 36,957 patients admitted during that 6 month time period of which a total of 358 cases of AKI were identified. There was total of 183 male patients and 171 female patients. Four of the male patients had a further AKI alert during the same hospital admission. The mean age was 72.18 years. Pre-renal causes were identified as the main contributors to the cases. Majority of the AKI alerts were Stage 1 AKI which was 70%, Stage 2 AKI was 25% and Stage 3 AKI was 5 % of the total cases. The data also revealed that the average length of stay (ALOS) did not differ in each of the stage. A patient ALOS for Stage 1 AKI 23.3 days, Stage 2 AKI 24 days and Stage 1 AKI 21 days. Of the total number of cases of patients with AKI, 50.6% (179/354) of the patients had died within the 12 months period. Looking into the mortality rate of each individual stages of AKI; the mortality rate at 12 months for Stage 1 AKI is 46.5%. For Stage 2 AKI, 62.7% and for Stage 3 AKI, 47.6%.

Conclusions: From the date collected, it shows that the degree of AKI does not affect the length of stay of patients. Despite the different stages of AKI indicating the severity of the injury, mortality rate for Stage 1 and Stage 3 did not differ. This indicates that AKI carries a high mortality rate regardless of the severity of the injury. Early recognition leads to early intervention in the prevention of AKI.

FR-PO480

Acute Kidney Injury: Adding Informatics to Injury – (Electronic Injury Alerts) Conor Patrick Moran,[1] Ying C. Kuan,[1] Patrick Lm Lynch,[2] Francis Mccarroll.[1] *[1]Dept of Nephrology, Altnagelvin Hospital, Londonderry, United Kingdom; [2]Dept of Clinical Chemistry, Altnagelvin Hospital, Londonderry, United Kingdom.*

Background: Acute Kidney Injury, (AKI), is common with a variably reported mortality, (15-60%). UK national audit reported that up to 30% of cases were avoidable and that as much as 43-61% of post-admission AKI experienced an unacceptable delay in recognition of insult. There has been a paucity of work with regards to AKI recognition and prevention. National guidelines have recommended the use of electronic alerts (e-alerts) for AKI detection.

Methods: We introduced AKI e-alerts with accompanying electronic guidance in late October 2014 and prospectively collected data on the patients identified with severe AKI. Data collection was carried out for 3 months, (n=110). The demographics of this cohort were compared with a historical cohort of severe AKI (n=89).

Results: Mean age, (72 years vs. 73 years), gender distribution, (M:F: 46% / 54% vs. 47% / 53%), and median time to death, (10 days vs. 9 days), were comparable. Thirty day mortality was similar with regards to hospital acquired AKI, (27.3 % vs. 26.1%). 30 day mortality was significantly lower for community-acquired AKI: (10.7%). Mean and median age was demonstrated to be higher in the group of patient who died, (Mean: 80.1 years vs. 75.7 years), (Median: 82 years vs. 82 years) – negative skew due to outliers.

Conclusions: Although our initial data suggests an electronic AKI alert has no discernable effect on 30 day mortality rate and time to death. We feel that e-alerts with the addition of further Quality Improvement work will eventually result in a steady reduction in AKI mortality.

FR-PO481

Tenofovir Nephrotoxicity Is an Important Cause of Acute Kidney Injury in HIV Infected Inpatients Teg Marcos Veiga, Adriana Belo Prazeres, Daiane Silva, Gisele Vajgel Fernandes, Geraldo Jose de Amorim, Luis H.B.C. Sette, Lucila Maria Valente. *Nephrology, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.*

Background: Tenofovir disoproxil fumarate (TFD) is widely prescribed as a first choice therapy for HIV infection, because of its convenient dosing schedule, efficacy and relatively low side effects. However, renal toxicity may lead to acute kidney injury (AKI), chronic kidney disease (CKD), and proximal tubular injury. Here we describe clinical characteristics and outcomes of AKI associated to TDF.

Methods: In a retrospective cohort (between Mar/2011 to Feb/2015), we have described data of HIV-infected inpatients, in a single center infectious disease ward, referred to the Nephrology group due to AKI. AKI was defined according to AKIN criteria.

Results: During the study period, 72 patients were evaluated; the baseline characteristics are showed in table1. Nephrotoxic AKI was present in 36 cases, of which 19 cases (52%) were associated withTFD and the drug was withdrawn in all cases. Seven patients had TFD nephrotoxicity without other associated factors and only three patients achieved renal function recovery, but no one needed dialysis or died during follow up.

Parameters	N=19
Age	41.3 ± 11.3
Male	11 (58%)
Charlson Comorbidity Index	8
SCr baseline (mg/dL)	0.89
SCr at referral (mg/dL)	3.35
AKIN 1 2 3	 4 (21.0%) 3 (15.8%) 11 (58%)
Use of other nephrotoxic drug	6 (31.6%)
UCI admission	5 (26.3%)
Follow up (days)	19.3
Hemodialysis	7 (36.8%)
Renal function recovery*	8 (42%)
Mortality Hemorrhagic shock	4 (21.0%) 1 (25.0%)
Sepsis	3 (75.0%)

* Definied as recovery to baseline SCr ± 25%

Conclusions: AKI associated to TFD nephrotoxicity was very prevalent in the HIV infected inpatients and showed high morbidity, including almost a third of patients requiring dialysis and more than a half not recovering renal function after withdrawing the drug.

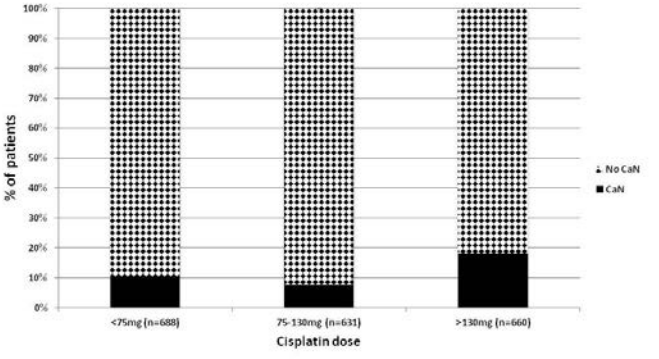
FR-PO482

Cisplatin-Associated Nephrotoxicity: Not as Frequent as Previously Reported Shveta S. Motwani, Sushrut S. Waikar, Benjamin D. Humphreys, Gary C. Curhan. *Nephrology, Brigham and Women's Hospital, Boston, MA.*

Background: Cisplatin-associated nephrotoxicity (CaN) is a frequent problem amongst patients with various cancers. Most older studies have reported 25-30% of patients who receive cisplatin experience acute kidney injury. However, these data have not been re-evaluated systematically recently despite rapid advances in oncologic care. Therefore, we examined the proportion of patients who develop acute kidney injury after exposure to the first cycle of cisplatin in a large patient database. We also examined the frequency of kidney injury stratified by sex and cisplatin dose regardless of cancer type.

Methods: We collected data on patients ≥ 18 years of age who had received cisplatin as a primary, secondary or adjuvant or neo-adjuvant therapy at a tertiary-care medical center (Massachusetts General Hospital) between 2006 and 2014. Detailed data regarding cisplatin dose, demographic characteristics, concurrent medical history and laboratory data including serum creatinine (Cr) and electrolytes were collected. CaN was defined as an elevation of Cr by ≥ 0.3 mg/dl during a 14 day period after administration of cisplatin (peak Cr)compared with baseline (bl Cr). Patients with bl Cr of >1.5 were excluded.

Results: Of the 1979 patients in our study, 55% were male with a mean ± SD of age of 61.6 ± 12.8, A bl Cr was 0.9 ± 0.2. 241 of 1979 (12.2%) patients developed CaN. However, it ranged from 7.8% in the medium dose group (cisplatin dose 75-130 mg) to 18.2% in the high dose group (>130mg) without a clear dose response relation.



In addition, a significantly lower frequency of CaN was noted amongst females compared with males (9.3% vs 14.5%, p<0.001).

Conclusions: Cisplatin-associated nephrotoxicity occurs less frequently than previously reported. This may reflect changes in preventive care such as more aggressive hydration with electrolyte-rich solutions.

FR-PO483

Characteristics of 681 Patients with Atypical Hemolytic Uremic Syndrome in the Global aHUS Registry Christoph Licht,[1] Gianluigi Ardissino,[2] Gema Ariceta,[3] David J. Cohen,[4] Christoph Gasteyger,[5] Larry A. Greenbaum,[6] Sally A. Johnson,[7] Masayo Ogawa,[8] Varant Kupelian,[8] Franz S. Schaefer,[9] Johan Vande Walle,[10] Veronique Fremeaux-bacchi.[11] *[1]The Hospital for Sick Children, ON, Canada; [2]Fondazzione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Hospital Univ Vall d'Hebron, Barcelona, Spain; [4]Columbia Univ Medical Center, NY, NY; [5]Alexion Pharma International Sarl, Lausanne, Switzerland; [6]Emory Univ, Atlanta, GA; [7]Great North Children's Hospital, Newcastle, United Kingdom; [8]Alexion Pharmaceuticals, Inc., Cheshire, CT; [9]Heidelberg Univ Hospital, Heidelberg, Germany; [10]Univ Hospital Ghent, Ghent, Belgium; [11]Assistance Publique, Paris, France.*

Background: The observational atypical hemolytic uremic syndrome (aHUS) Registry collects patient (pt) information and facilitates availability of follow-up data for eculizumab (ECU).

Methods: Pts with clinical diagnoses of aHUS (irrespective of identified complement abnormality or treatment) are eligible. Demographic, medical/disease history, and treatment outcomes data are collected at enrollment and prospectively.

Results: By January 30, 2015, 681 pts enrolled (**Table**); 62.7% of adults were women. Thrombosis occurred more frequently in adults than pediatric pts. Nonrenal comorbid conditions occurred in both age groups. ECU was administered to 56.2% (87.7% prior to enrollment).

Conclusions: Registry baseline characteristics show differences between pediatric and adult aHUS pts, notably different frequencies of thrombosis. Ongoing and future analyses will further enhance understanding of aHUS history and progression. Medical writing support - Kristen W. Quinn, PhD, of Peloton Advantage, funded by Alexion

Table. Characteristics of Patients Enrolled in the Global aHUS Registry by January 30, 2015.

Characteristics	<18 Years of Age[a] (n=257)	≥18 Years of Age[a] (n=405)	Total (N=681)

FR-PO484

Long-Term Renal Function After Recovery from Dialysis-Requiring Acute Kidney Injury Sokratis Stoumpos, Colin C. Geddes. *Renal and Transplant Unit, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Current guidelines suggest that people should be monitored for the development of chronic kidney disease (CKD) for at least 2-3 years after acute kidney injury (AKI), even if serum creatinine has returned to baseline. The aim of this study was to determine the long-term renal outcome of patients experiencing AKI secondary to hypoperfusion injury and/or sepsis who recovered to apparently normal renal function.

Methods: We conducted a population-based cohort study of all adult patients in our catchment area (serving a population of approximately 1.5 million), with AKI who required in-hospital dialysis in the nephrology unit, survived for at least 12 months after discharge and had estimated glomerular filtration rates (eGFR) greater than 60mL/min 1 year after the episode of AKI between September 1, 1989, and March 5, 2015. Patients with underlying nephropathy and AKI due to causes other than hypoperfusion injury and/or sepsis were excluded. Follow up was censored to the date of the last serum creatinine recorded.

Results: From the 770 patients identified with dialysis-requiring AKI, 310 patients met the study inclusion criteria. Mean age at time of AKI was 49.0 (SD 16.4) years, 58.7% were male and the median duration of haemodialysis was 6 (IQR 3-11) days. After a median follow-up of 7.3 (IQR 4.6-12.6) years from first dialysis for AKI, eGFR was >60mL/min in 285 (91.9%) patients, 45-59mL/min in 18 (5.8%), 30-44mL/min in 6 (1.9%) and 15-29mL/min in 1 (0.3%) patient. None of the patients developed CKD stage 5 or end stage renal disease. 86 (27.7%) patients died during the duration of follow-up.

Conclusions: The excellent outcome for patients with normal renal function 1 year after an episode of dialysis-requiring AKI suggests that these patients are unlikely to derive benefit from life-long follow up of kidney function after AKI.

FR-PO485

Use of ACEIs and ARBs in Patients with Chronic Kidney Disease and Superimposed Community-Acquired Acute Kidney Injury Patrick Saudan,[1] Cyrielle Alves,[2] Fabien Stucker,[3] Belen Ponte,[1] Pierre-Yves F. Martin,[1] Thomas Perneger,[4] Sebastian Carballo.[2] *[1]Nephrology Unit, Depatment of Medical Specialties, Geneva Univ Hospitals, Geneva, Switzerland; [2]Dept of General Internal Medicine, Geneva Univ Hospitals, Geneva, Switzerland; [3]Nephrology Unit, Hôpital de la Providence, Neuchatel, Switzerland; [4]Clinical Epidemiology Unit, Geneva Univ Hospitals, Geneva, Switzerland.*

Background: Due to their long-term nephroprotective effect, ARBs and ACEIs are often used in patients with CKD despite their association with an increased risk of superimposed AKI. We aimed to better define its occurrence in relation to their use.

Methods: We undertook a prospective observational study within the Emergency Department, screening for any patient > 16 years admitted with an eGFR < 60 ml/mn. Patients with CKD (previously known for an eGFR < 60 ml/mn) were included and superimposed AKI was defined as a decline in eGFR compared to previous values according to KDIGO AKI criteria.

Results: From May 1st up to June 21st 2013, there were 8464 admissions of whom 361 (4%) had a eGFR < 60 ml/mn and were known to have CKD. Use of ACEIs, ARBs, diuretics, NSAIDs was respectively found in 19, 23, 37 and 4 % of patients. AKI was superimposed in 102 (28%) CKD patients. Etiology was prerenal (73%), renal (17%) and postrenal (9%).Stage I/II/III AKI were 87, 5 and 8% respectively. One year survival rates were 81 and 78 % (p=0.62) in patients with stable CKD and those with superimposed community-acquired AKI. Multiple logistic analysis showed that its occurrence was associated with male gender (OR 2.03; 95%CI:1.23-3.35, p=0.005), diuretic use (OR 1.61; 95%CI:1-2.60, p=0.05) and ARBs use (OR 1.61; 95%CI:1-2.60, p=0.05). ACEIs use was found to be slightly nephroprotective (OR 0.49; 95%CI:0.25-0.96, p=0.04).

Conclusions: Mild community-acquired superimposed AKI in CKD patients does not seem to increase one year-mortality and is more frequently encountered in male patients and those treated with diuretics and ARBs, but not ACEIs. Although their impact on renal hemodynamics is supposed to be similar, further studies should be implemented in CKD patients to examine whether ARBs are more detrimental than ACEIs in terms of risk of superimposed AKI.

FR-PO486

Renal and Patient Outcomes of Dialysis Dependent Patients with ATN Who Survive Hospitalization Mohammad Alhaji, Rabeeh I. El-refadi, Jerry Yee, Bronwyn Larissa Small, Javier Rodriguez Sanchez, Jian Li, Lenar T. Yessayan. *Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: Acute tubular necrosis **(**ATN) accounts for the majority cases of acute kidney injury (AKI) in critical care units. The in-hospital mortality rate of dialysis requiring ATN in critically ill patients exceeds 50%. However, renal and patient outcomes among dialysis dependent patients with ATN who survive the hospitalization are lacking.

Objective: To determine 90 day renal recovery and mortality rates, 1 year cardiovascular and hospital readmission rates of patients with ATN discharged on hemodialysis.

Methods: We prospectively enrolled 38 Medicare beneficiaries who developed hemodialysis-dependent ATN and survived to discharge at a single center from January 1, 2013 to June 30, 2014. The ATN was identified by urine microscopy and clinical judgment. ATN causes, patients' comorbid conditions, potential contributors to ATN and indications for RRT were recorded. Cumulative hazard estimates of events and survival curves were generated using the Kaplan-Meier method.

Results: Twenty six patients (38%) had CKD**,** 18 had diabetes (47%), 29 had hypertension (76%), 10 had history of liver disease (26%).The 90 day renal recovery and mortality rates were 42% and 11% respectively. Of those who recovered kidney function, Only 1 patient recovered kidney function beyond 60 days. The 1 year cardiovascular event rates and readmission rates were 22% and 62% respectively.

Conclusions: Patient with dialysis dependent ATN following a hospitalization are unlikely to get off dialysis support beyond 60 days after discharge. In the first year post discharge, they experience a significant number of cardiovascular events and hospital readmissions. Identifying modifiable risk factors for readmission in this cohort may reduce health care costs.

FR-PO487

Long-Term Follow-Up of Children with STEC-HUS Caused by *E. coli* O104:H4 (German HUS Outbreak 2011): A GPN Registry
Markus J. Kemper,[1] Wiebke Aulbert,[1] Thurid Ahlenstiel-Grunow,[2] Brigitta Kranz,[3] Jun Oh.[1] *[1]Pediatric Nephrology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Pediatric Nephrology, Medizinische Hochschule, Hannover, Germany; [3]Pediatric Nephrology, Univ Hospital, Münster, Germany.*

Background: In 2011 E. coli O104:H4 caused the largest outbreak of HUS in adults and children. A total of 90 children were affected, of whom 64 (71%) required dialysis for a median of 11 days.

Methods: Currently follow-up data are available from 60 of 90 children (67%, 31 girls) from 11 pediatric centers in Germany. Median follow-up is 2.7 (range 1.2-3.6) years, median current age of patients is 14.7 (3.4-18.7) years.

Results: Median current serum-creatinine is 0.7 (0.3-8.9) mg/dl. In two patients (2.2%) with CKD stage 3 and 4 at discharge GFR improved and they are now in CKD Stage 2. One patient remained dialysis dependent initially and one reached ESRD after 3.5 years; both underwent successful living-related kidney transplantation. All these 4 patients were treated with eculizumab in the initial phase of STEC-HUS including 2 who also received plasmapheresis. Proteinuria is currently present in 17 (19%) patients and 9 (10%) require treatment for hypertension. Three patients have neurologic symptoms (headache, performance deficit, spastic movement disorder) and 3 patients have EEG abnormalities without symptoms.

Conclusions: Long-term follow-up is important after O104:H4 associated STEC-HUS. CKD stage 3-5 at discharge is a risk factor for ESRD, however some children show a significant improvement over time. Patients with proteinuria and hypertension need long-term follow-up. Follow-up studies after STEC HUS should include neurological investigations.

FR-PO488

SOFA Scores as Predictors of Mortality and Dialysis Dependency in Acute Kidney Injury
V. Shane Pankratz,[1] Christos Argyropoulos,[1] Khaled Abdel-Kader,[2] Kelly V. Liang,[3] Paul M. Palevsky,[3] Mark L. Unruh.[1] *[1]Dept of Internal Medicine, Div of Nephrology, Univ of New Mexico School of Medicine, Albuquerque, NM; [2]Dept of Medicine, Div of Nephrology and Hypertension, Vanderbilt Univ School of Medicine, Nashville, TN; [3]Dept of Medicine, Renal-Electrolyte Div, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: The Sequential Organ Failure Assessment (SOFA) score measures the severity of organ failure, and baseline SOFA scores have been used to predict mortality in patients with Acute Kidney Injury (AKI). We evaluated whether SOFA scores, either upon initiation of dialysis or clinically updated, predict mortality and dialysis dependency following AKI.

Methods: Data from patients enrolled in the Acute Renal Failure Trial Network (ATN) study, a randomized multicenter trial of the intensity of renal support in AKI, were used in Cox proportional hazards regression and multinomial logistic models to assess the degree to which SOFA scores predict mortality and dialysis dependency.

	Odds Ratio(95% Confidence Interval)		
Endpoint	**Day 28**	**Day 60**	**1-year**
Death	1.23(1.18-1.28)	1.20(1.15-1.24)	1.17(1.13-1.21)
Dialysis Dependency	0.92(0.89-0.96)	0.91(0.87-0.96)	0.87(0.79-0.95)

Results: SOFA scores were associated with increased mortality risk following AKI among the 1,124 ATN participants, but the concordance statistic was low, at 0.651 (standard error [se]=0.014). When time-dependent analyses were used to take advantage of prospectively updated SOFA scores, the concordance statistic increased to 0.753 (se=0.013). In analyses that examined mortality and dialysis dependency as competing outcomes at three fixed time points, increased SOFA scores were associated with higher mortality risk, and lower risk of dialysis dependency.

Conclusions: Similar to the general ICU population, updated SOFA scores better prognosticate the risk of death in patients with AKI. Higher SOFA scores are associated with increased mortality risk, but decreased dialysis dependency risk, when the two outcomes are evaluated as competing risks. Future studies should focus on prognostic tools that simultaneously prognosticate survival and need for dialysis in AKI patients.

FR-PO489

Risk Factors of Acute Kidney Injury and In-Hospital Mortality in Adult Patients Receiving ExtraCorporeal Membrane Oxygenation (ECMO)
Sung Woo Lee,[1] Seon Ha Baek,[1] Jae Yoon Park,[2] Shin-Young Ahn,[1] Sejoong Kim,[1] Ho Jun Chin,[1] Dong-Wan Chae,[1] Ki Young Na.[1] *[1]Seoul National Univ Bundang Hospital; [2]Seoul National Univ Hospital.*

Background: Although acute kidney injury (AKI) is the most frequent complication in patients receiving extracorporeal membrane oxygenation (ECMO), little has been studied about the risk factors of AKI and in-hospital mortality. Thus we performed the study to identify factors associated with AKI and in-hospital mortality.

Methods: We analyzed 322 adult patients receiving ECMO from January 2005 to November 2014 in two tertiary care hospitals. AKI and its stages were defined by Kidney Disease Improving Global Outcomes classifications. Variables within 24 h before ECMO initiation were collected and analyzed for the association with AKI and in-hospital mortality.

Results: Stage 3 AKI was associated with in-hospital mortality with HR (95% CI) of 2.690 (1.410-5.132), compared to no AKI (p=0.003). Simplified acute physiology score 2 was also significantly associated with in-hospital mortality with HR (95% CI) of 1.022 (1.004-1.040) with every 1 score increase (p=0.014). Initial pump speed of ECMO was significantly related to in-hospital mortality with HR (95% CI) of 1.397 (1.024-1.904) with every 1000 rpm increase (p=0.035). The pump speed was also significantly associated with total AKI (p=0.035) and stage 3 AKI (p=0.044) with ORs (95% CI) of 2.219 (1.059-44.652) and 1.676 (1.015-2.770), respectively. We also found that red cell distribution width (RDW), serum level of total bilirubin, and the duration of ECMO were significantly related to AKI and/or stage 3 AKI.

Conclusions: Initial pump speed was significant risk factor of in-hospital mortality and AKI in patients receiving ECMO. RDW, serum level of total bilirubin and the duration of ECMO were risk factors of AKI.

FR-PO490

Comparison of Clinical Characteristics of Patients with Acute Kidney Injury After Intravenous versus Inhaled Colistin Therapy
Hyunju Yoon, In O Sun, Kwang Young Lee, A young Cho. *Div of Nephrology, Dept of Internal Medicine, Presbyterian Medical Center, Jeonju, Jeonbuk, Republic of Korea.*

Background: The aim of this study is to investigate the incidence and clinical characteristics of intravenous or inhaled colistin associated acute kidney injury (AKI) using the RIFLE criteria.

Methods: From 2010 to 2014, 160 patients were treated with intravenous or inhaled colistin. Of these, we included 139 patients who received colistin for >72 h, and compared the incidence and clinical characteristics of patients in the intravenous (n=120) and inhaled (n=19) groups.

Results: The patients included 116 men and 23 women, with a mean age of 68 years (range, 20-91). Patients were infected with either *A. baumannii* (54%) or *P. aeruginosa* 46 (%), and pneumonia (91%) was the most common type of infection. The mortality rate was 43.9%, and AKI occurred in 83 (60%) patients. At the end of therapy, bacteriologic cure rate was 64%. There were no differences in the clinical characteristics between the intravenous and inhaled groups except for age. In comparison with patients in the intravenous group, the patients in the inhaled group were older (74 ± 8 vs 67 ± 14 years, p=0.03). The incidence of AKI was not different between the two groups (62% vs 47%, p=NS), and there was no difference in the severity of AKI according to the RIFLE criteria. Of the 83 patients with AKI, 8 and 1 patients underwent renal replacement therapy.

Conclusions: In our study, the incidence of AKI in patients undergoing colistin therapy was 60%, and there was no difference in safety between the intravenous and inhaled colistin groups. Therefore, it is also important to monitor renal function during colistin therapy regardless of the route of administration.

FR-PO491

Acute Kidney Injury following Coronary Angiography
Dadi Helgason,[1] Þórir E. Long,[1] Gisli H. Sigurdsson,[2] Martin I. Sigurdsson,[3] Olafur S. Indridason.[4] *[1]Dept of Medicine; [2]Deparment of Anesthesia, Landspitali; [3]Dept of Anesthesia, Brigham and Women´s Hospital, Boston, MA; [4]Div of Nephrology, Landspitali - The National Univ Hospital of Iceland, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) is a known complication of coronary angiography (CA). The aim was to study the incidence, risk factors and outcome of AKI following CA in a whole nation.

Methods: This was a retrospective analysis of data from all CA in Iceland during a 9 year period. AKI was diagnosed according to the creatinine based KDIGO criteria and survival status for all patients was verified at Statistics Iceland. The epidemiology and clinical outcomes were compared between three 3-year periods using Chi-squared and Kaplan Meier method, and multivariate logistic regression was performed to find predictors of AKI.

Results: From Jan 1st 2005 to Dec 31st 2013 10713 patients underwent 13890 CA of whom 40% entailed an intervention. Median (range) age was 65 (19-96) years and 70.7% were men. AKI was diagnosed in 214 patients (1.5%); 168 (1.2%), 27(0.2%) and 19 (0.1%) of stage 1, 2 and 3, respectively. There was a trend towards a decreasing incidence of AKI: 1.8% in the first 3 year period, 1.3% in the second and 1.4% in the last (p=0.05). AKI was more common in the intervention group, 2.2% vs. 1.1% (p<0.0001). Patients with AKI were older, had more often prior history of AKI, more co-morbid diseases and lower baseline eGFR compared to non-AKI patients. In multivariate analyses age over 70 years (OR=1.01, 95% CI= 1.007-1.016), angiography with intervention (OR=1.01, 95% CI=1.008-1.016) COPD (OR=1.01, 95% CI =1.003-1.025), liver disease (OR=1.03, 95% CI=1.014-1.058) baseline eGFR<60 (OR=1.03 95% CI 1.027-1.039) and a prior history of AKI (OR=1.07, 95% CI= 1.051-1.080) were independent predictors of AKI after CA. One year survival of AKI patients did not differ between time periods: 67.0%, 63.1% and 69.0% in the first, second and third, respectively, p=0.3).

Conclusions: There is a trend towards a decrease in AKI incidence following CA in recent years. Aged patients with multiple co-morbidities and prior history of AKI need special attention in connection with this this procedure.

Funding: Private Foundation Support

FR-PO492

Acute Kidney Injury in the First Hundred Days After Hematopoietic Stem Cell Transplantation: Experience with 222 Transplanted Patients in a Single Center Miguel A. Solis, Sandra Tejedor, Isidro Torregrosa, Carmen Ramos, Isabel Juan, Patricia Tomas, Patricia Zambrano Esteves, Juan José Guzmán Herrera, Maria Jesus Puchades, Alfonso M. Carrasco. *Nephrology, Univ Clinic Hospital, Valencia, Spain.*

Background: Hematopoietic stem cell transplantation recipients are at an increased risk of Acute Kidney Injury (AKI) or Chronic Kidney Disease (CKD). An earlier diagnosis could dramatically improve the patients' prognosis. **Objective.** To analyze the incidence of AKI in the first 100 days of Hematopoietic stem cell transplantation recipients and the relationship with mortality.

Methods: We carried out a retrospective study including 222 adult patients who underwent Hematopoietic stem cell transplantation between 2006 and 2010 at our institution. AKI was defined using the RIFLE criteria in the first 100 days after transplantation.

Results: 222 patients were included in the study, 137 males and 85 females. Median follow-up was 30 months, range 1-60 months. In the first 100 days after transplantation AKI developed in 78 patients according to the RIFLE criteria (35.1%). A total of 85 patients died during follow-up vs 47 who had developed AKI (38,2% versus 61%, p<0.05).Detailed patients´characteristics are summarized in table 1.

Sex	Male: 137. Female: 85
Median Age, years.	48.9,SD 13.43.
Type of transplantation.	**Autologus:** 117 (52.7%) **Allogeneic:** 105 (47.3%) ablative: 57 (25.7%) non ablative (miniAlo): 48 (21.6%)
Previous transplantation.	37(16.7%)
Follow-up, months.	30, range 1 to 60.
AKI. RIFLE criteria. 78 (35.1%)	**R** 36 (16.2%) **I** 30 (13.5%) **F** 9 (4.1%)
AKI in Type of Transplantation.	Autologus: 11.1% Allogeneic: 59.6% miniAllo: 66.7%
Overall Mortality	85 (38.2%)
Mortality in AKI.	47 (61%)

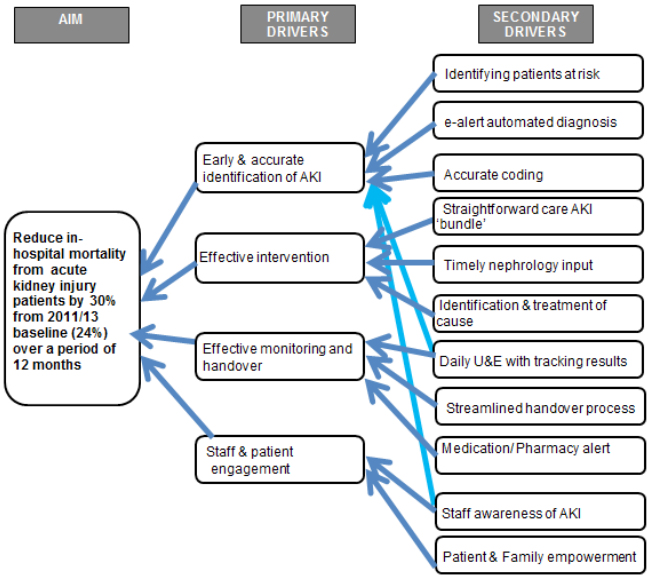
Conclusions: AKI incidence in hematopoietic stem cell transplantation recipients is very high. There is a statistically significant relationship between AKI and death in these patients. Earlier AKI identification could prevent kidney damage progression and improve patient outcome over time.

FR-PO493

STOP-Acute Kidney Injury (AKI): A Streamline Approach to the Management AKI Leads to Reduction of Mortality Rates Hsu pheen Chong, Thangavelu Chandrasekar. *Nephrology, Aintree Univ Hospital, United Kingdom.*

Background: Acute Kidney Injury (AKI) has a mortality rate of 30%, greater than common conditions such as myocardial infarction (8%) and stroke (9%). It is estimated that 15% of all inpatients at University Hospital Aintree (UHA), Liverpool, UK, suffer an AKI making it a condition of considerable importance in everyday practice. Through clinical audit, it was found that mortality rate of AKI in UHA was 33% on wards other than renal ward (9%).

Methods: To reduce AKI mortality by 30% and length of stay by 20% over a 12 month period from Oct 2013 using standardised, evidence based approach. Using plan, do, study act (PDSA) methodology, we developed and tested an automated e-alert diagnostics system, an AKI treatment bundle and a patient information leaflet. The STOP-AKI project was launched. Our Primary drivers were early and accurate identification of AKI, effective intervention and monitoring, staff and patient engagement. Initially, trialled at ward level, the project was scaled up to admission areas (Accident and Emergency Department and the Medical Assessment Unit) becoming part of routine management for all admitted patients.



Results: Fall in mortality rates from a baseline of 24% to 18.5 %, representing an overall reduction in mortality of 23%. Length of stay fell by 11% equating in a 2.0 day reduction in length of stay.

Conclusions: The STOP-AKI project led to the development of an AKI bundle in Oct 2013. This has achieved not only a significant reduction in patient mortality and length of stay but in addition a more structured and stream lined way of approaching the patients with AKI in our hospital. With the bundle being rolled out to primary care and the rest of our inpatient wards, we anticipate a further reduction in mortality.

FR-PO494

Race and Risk of Acute Kidney Injury (AKI) in VA Patients Michael Heung,[1] Diane Steffick,[1] Deidra C. Crews,[2] Neil R. Powe,[3] Sharon Saydah,[4] Meda E. Pavkov,[4] Kara Zivin,[1,5] Rajiv Saran.[1] *[1]Univ of Michigan; [2]Johns Hopkins Univ; [3]Univ of California San Francisco; [4]Centers for Disease Conrol and Prevention; [5]VA Ann Arbor Health System.*

Background: African Americans (AA) are at increased risk for AKI compared to Caucasians (C); potential explanations include differences in risk factors, genetic susceptibility and socioeconomic factors. We explored the influence of race on AKI risk in the Veterans Administration (VA), an integrated healthcare system.

Methods: Retrospective cohort analysis of all hospitalizations for VA patients with known AA or C race in 2011. AKI was defined by KDIGO criteria (>= 0.3mg/dL increase in serum creatinine from pre-admission baseline). Modified Poisson regression models estimated the effect of AA race on risk of AKI, adjusting for age, sex, baseline eGFR, comorbidities (DM, HTN, coronary heart disease,CHD; CHF), geographic region and severity of illness during hospitalization. Additional models including albuminuria were run for those with available data.

Results: We identified 180,429 VA hospitalizations. Compared to C, AA had higher prevalence of DM (43.1% v. 41.1%, P<.001), lower prevalence of CHD (45.7% v. 58.8%, p<.001), lower Charlson comorbidity scores (1.4 v. 1.6, p<.001) and higher baseline eGFR (89.2 v. 81.7, p<.001). AKI occurred in 19.5% of admissions (35,134) involving 23.2% of AA and 18.5% of C. In adjusted models, AA race remained an independent risk factor for AKI (RR 1.26, 95% CI 1.24-1.28). In the subgroup with albuminuria data (40,668), the risk was slightly attenuated (RR 1.20, 95% CI 1.16-1.24). A similar increased risk of hospital-acquired AKI in AA compared to C (RR 1.19, 95% CI 1.15-1.23) was found.

Conclusions: Although AA Veterans had higher baseline eGFR and lower comorbidity scores compared to C, AA had an increased risk of developing AKI, even after accounting for differences in risk factors & geographic region. This increased risk for AKI in AA persisted when examining AKI that developed during hospitalization. Given that VA patients have similar healthcare access and benefits, our results suggest that the increased AKI risk seen in AA is unlikely to be fully accounted for by disparities in access to care.

Mortality Risk Factors in Mexican Patients with Acute Kidney Injury Luis Alberto Evangelista-Carrillo,[1] Enrique Rojas-Campos,[2] Salvador Mendoza Cabrera,[1] Benjamin Gomez-Navarro.[1] *[1]Nefrologia y Trasplantes, IMSS, Guadalajara, Jalisco, Mexico; [2]Unidad Médica de Investigación en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.*

Background: Acute Kidney injury (AKI) data in Latin American is scarce.

Methods: Aim: To determine patient survival, mortality risk factors and treatment in AKI patients from a tertiary hospital. **Methods:** Prospective cohort Dic 2010-2012 of 275 patients with AKI whom need Nephrology consultation. Recollected data at admission,

Nephrologists consultation and 30 days follow up included demographics and biochemical variables, time between AKI onset and Nephrology consultation, fluid balance, mortality scale, treatment and date of death or patient discharge.

Results: The overall mortality was 49%. Mean age 58 years. The principal diagnosis at admission was coronary syndrome. The AKI at the moment of consultation was 3 in the 64%.

VARIABLE	CONSERVATIVE	HEMODIALYSIS	CRRT
Age (mean)	60.8± 17.7‡	53.1± 19.1	58.3± 16.7
Nephrology consultation (time since first creatinine increase hours)	50.5± 48.9	71.7± 69.8	61.3± 83.5
Mortality (%)	38	52.9	72
24 hrs uresis (L)	2.1±1.4 ‡	1.2±1.4	1.4±1.2
Fluid gain	3.1±4.4 ‡	4.5±4.8	6.6±6.2
Base creatinine (mg/dl)	0.96±0.26	1.01±0.35	1.02±0.30
Creatinine at nephrology consultation	2.98±2.04 ‡	4.97±3.21	2.92±1.72
APACHE II	19±6‡	20±5	24±5

‡p<0.05

Difference in characteristics accord therapy.

Mortality prediction analysis

$\chi 2 = 30.35$; $p<0.0001$

Variable	(RR)	IC 95% RR	Valor p
Admission site (ICU)	0.46	(0.3-0.71)	<0.001
Without diuretic *	0.48	(0.24-0.95)	0.04
Without vassopresor*	0.35	(0.18-0.65)	<0.05
24 hrs uresis	1.00	(0.99-1.00)	0.048
Fluid gain	1.00	(1.0 – 1.0)	0.053
Δ Creatinine*	0.85	(0.73-0.96)	0.02
Time since first increased in creatinine and nephrology consultation *	1.13	(0.89-1.4)	0.33

*At the moment of Nephrology consultation

Mortality predicted analysis.

Conclusions: This is the first report of epidemiology of AKI in Mexico. The conservative treatment is associated with mortality. The consultation with nephrology was late. Use of diuretic, vasopressor and uresis less than 1 liter per day at the nephrology consultation time were associated with mortality.

FR-PO496

Cast Nephropathy versus Acute Tubular Necrosis in Newly Diagnosed Multiple Myeloma: A Comparative Study Insara Jaffer Sathick,[1] Samih H. Nasr,[2] Nelson Leung.[1,3] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Div of Anatomic Pathology, Mayo Clinic; [3]Div of Hematology, Mayo Clinic, Rochester, MN.*

Background: Myeloma cast nephropathy (MCN) and acute tubular necrosis (ATN) are recognized causes of acute kidney injury (AKI) in newly diagnosed multiple myeloma patients. However it is currently not known if there is a difference in outcomes between these two groups. We conducted a retrospective study to compare the clinical characteristics and renal response rates in patients presenting with acute kidney injury at the time of myeloma diagnosis.

Methods: We included all patients with AKI at the time of multiple myeloma diagnosis with biopsy-confirmed diagnosis of MCN or ATN between 1998 and 2013. Patients with chronic kidney disease (estimated GFR by MDRD equation<45ml/min/1.73m2) and relapsed multiple myeloma were excluded. We assessed survival and renal outcomes. Six month landmark survival analysis was done with Kaplan Meier estimates. Renal response was classified according to IKMG consensus criteria.

Results: Out of a total of 51 patients who were included in the study, 42 had MCN and 9 had ATN. Baseline characteristics were not significantly different between the groups except urine albumin percentage of >6% was predictive of ATN.

	MCN (n=42)	ATN (n=9)	p value
Median Age, years	63	64	0.19
Gender, M:F %	60:40	56:44	0.4
eGFR at presentation by MDRDml/min/1.73m2	9.8	11.6	0.3
Serum M spike(g/dl)	0.6	1.4	0.2
Proteinura(g/day)	3.1	2.7	0.2
Urine albumin >6%	37%	77%	**0.03**
Serum free light chain level(mg/dl)	680	596	0.3
Myeloma ISS stage 3	78%	81%	0.7
Calcium(mg/dl)	9.4	9.8	0.2
Dialysis requirement	51%	33%	0.3
Median duration of dialysis, days	95	21	0.4
Dialysis independence	42%	100%	**0.02**
Stem cell transplant for myeloma	60%	45%	0.3
Time to Renal Response, months	3.6	1.86	**0.04**
Time to Myeloma Response, months	7.3	8.4	0.7
Median Survival, months	49.7	57.1	0.4

Conclusions: Our data suggests that AKI due to ATN at the time of myeloma diagnosis is more likely to recover compared to MCN with a faster time to response. However this does not seem to affect overall survival.

FR-PO497

Hospital Manifesting AKI Presents Worst Outcome Than Community Acquired AKI Xose luis L. Perez-Fernandez,[1] Florentina E. Sileanu,[2] Joan Sabater Riera,[1] Kathleen D. Liu,[3] John A. Kellum.[2] *[1]Servei de Medicina Intensiva, Hospital Univ de Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain; [2]Critical Care, Univ Pittsburgh Medical Center, Pittsburgh, PA; [3]Nephrology & Critical Care, Univ California San Francisco Parnassus MC, San Francisco, CA.*

Background: The objective of this study was to evaluate outcomes in critically ill patients with severe community-acquired AKI (CA-AKI) and hospital-manifesting AKI (HM-AKI). Secondary objectives were to identify characteristics that differ between patients with CA-AKI and HM-AKI to design future preventive strategies.

Methods: Observational retrospective study conducted at two tertiary care hospitals between 2000-2008 (UPMC, Pittsburgh, USA) and 2006-2012 (HUB Barcelona, Spain). Those with CA-AKI met criteria for KDIGO Stage 3 AKI at hospital admission whereas those with HM-AKI did not have AKI at hospital admission. HM-AKI subjects met KDIGO Stage 3 AKI criteria within 24 hours of ICU admission, withat least 72 hours elapsing between hospital admission and ICU admission. The relationship of type of AKI (CA-AKI, HM-AKI) with 90-day survival was analysed using Cox regression models controlling for differences between survivors and non-survivors.

Results: 534 patients met inclusion criteria. 92.5% of these patients required RRT at some point during ICU admission. 189 (35.4%) patients had AKI manifest while in-hospital, and these patients had a significantly higher 90-day mortality compared to 345 (64.6%) patients presenting with CA-AKI (68.3% vs 58.6%; p=0.03). Age, SOFA score, time from hospital admission to ICU, HM-AKI (compared to CA-AKI), and medical (vs surgical) admission, were all associated with lower 90 day survival. In the multivariate analysis, HM-AKI remained an independent risk factor for death compared to CA-AKI (HR 1.5; 95%CI (1.1 – 2)).

Conclusions: AKI manifesting after hospital admission has significantly worse outcomes compared to AKI present at hospital admission even among patients progressing to stage 3 by ICU admission. Future interventions should be directed to prevent AKI in patients admitted to hospital, especially those who present with the risk factors identified in this study.

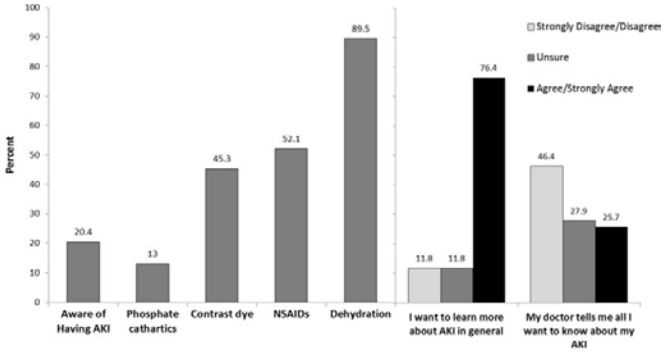
FR-PO498

Assessing Patient Awareness in Moderate to Severe Acute Kidney Injury Sharidan Parr, Marcus G. Wild, Swee-Ling Levea, Talat Alp Ikizler, Edward D. Siew, Kerri L. Cavanaugh. *Vanderbilt Center for Kidney Disease, Vanderbilt Univ Medical Center, Nashville, TN.*

Background: We aimed to evaluate awareness and knowledge of kidney disease in patients experiencing moderate to severe AKI, which is important for implementing targeted patient self-care risk-reduction strategies.

Methods: We surveyed 150 hospitalized patients in one academic medical center who experienced KDIGO Stage II or III AKI. We characterized patients' awareness that AKI had occurred, and specific AKI knowledge and perceptions about kidney communication from their health providers. Laboratory data, disease severity, nephrology consultation, and need for dialysis were abstracted from the medical record.

Results: Median participant age was 54 years; 53% were male; 81% were white; 90% had high school education or higher; 30% had health literacy scores ≤6; baseline serum creatinine (SCr) was 0.9 mg/dL; peak SCr was 2.9 mg/dL; 50% had Stage 2 AKI and 50% had Stage 3 AKI. In total, 80% of patients were unaware that they experienced AKI, including 7 patients requiring dialysis. Predictors of awareness included female gender (71% vs 41%), peak serum creatinine (4.5 vs 2.7), Stage III AKI (82% vs 42%), nephrology consultation (68% vs 31%), dialysis (29% vs 6%), duration of injury (6 vs 3 days), discharge SCr (2.2mg/dL vs 1.5mg/dL), and reporting a discussion of AKI with a provider during the hospitalization (43% vs 21%) (p values <0.05 for all comparisons). We found poor patient recognition of preventable causes of AKI and most patients desired more information [Figure 1].



Conclusions: Most patients with moderate to severe AKI are unaware of their condition, lack understanding of risk factors for future AKI, and desire more information about AKI. Optimizing AKI awareness and understanding to promote patient-centered communication and care will require targeted educational strategies during and after hospitalization.

FR-PO499

Acute Kidney Injury Correlates with Remote Organ Injury and Predicts Outcome in Primary Acute Liver Failure Alexander Lukasz,[1] Michael P. Manns,[3] Johannes Hadem,[3] Philipp Kümpers.[1] *[1]Dept of Nephrology and Rheumatology, Univ Hospital Muenster, Muenster, Germany; [2]Dept of Nephrology & Hypertension, Hannover Medical School, Hannover, Germany; [3]Dept of Gastroenterology, Hepatology and Endocrinology, Hannover Medical School, Hannover, Germany.*

Background: In patients with acute liver failure (ALF) acute kidney injury (AKI) is not well defined. In this study, we examine whether the occurrence of AKI predicts the combined endpoint of death or liver transplantation in a cohort of patients with primary ALF admitted to intensive care unit (ICU).

Methods: 130 patients with primary ALF of different entities (drug-induced, viral, indeterminate or others) were included. Patients without hepatic encephalopathy were excluded. According to the acute Acute Kidney Injury Network (AKIN) definition AKI severity (stage 1, 2 or 3) was classified. The primary outcome studied was event-free 28-day survival (death or transplantation).

Results: 76 patients (58%) had normal renal function, while AKIN I/II and III was present in 15 (12%) and 39 patients (30%) on ICU admission, respectively. Between different ALF entities, AKI prevalence and severity was similar (Chi-Square; p=0.28). AKI severity correlated closely with the extent of remote-organ damage as assessed by Simplified Acute Physiology Score (SAPS) III (r=0.56, p=0.0061) and Sequential Organ Failure Assessment (SOFA) score (r=0.57, p<0.0001), respectively. Kaplan-Meier analysis demonstrated that 37 of 39 ALF patients with AKIN III reached the composite endpoint of death or transplantation during 28-day follow-up compared to 59 of 76 no-AKI and 10 of 15 AKIN I-II, respectively (Log-rank test: p<0.0001). Adjusted Cox's proportional hazards analyses identified AKI on ICU admission as an independent predictor of the composite end point of death or transplantation [HR 3.1 (95% CI 1.9-4.9) for no AKI vs. AKIN III].

Conclusions: Our data indicate that AKI is a frequent complication in primary ALF. AKI correlates with several features of remote-organ damage and independently predicts outcome in this cohort.

FR-PO500

Reduction of Nephrotoxic Medication Associated Acute Kidney Injury: Results from a Three Year Sustained Harm Reduction Program Stuart Goldstein, Eric S. Kirkendall, Theresa A. Mottes, Kendria Nicole Simpson, Stephen E. Muething. *Pediatrics, Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Acute kidney injury (AKI) represents one of the most common co-morbidities in hospitalized children. Our previously reported nephrotoxic medication (NTMx) exposure and AKI screening project (Nephrotoxic Injury Negative by Just-in-time Action [NINJA]) showed a 25% NTM-AKI rate and a 42% reduction in AKI days/100 days of NTMx-exposure in Year 1 of the program. This occurred due to rapid recognition of AKI and NTMx-exposure reduction. We now report on the 3-year NINJA results to assess for sustained harm reduction.

Methods: A daily serum creatinine (SCr) was recommended for all children admitted to a non-critical care unit who received >3 NTMx simultaneously or an IV aminoglycoside for >3 days (high NTMx-exposure) to assess for AKI development. We tracked biweekly outcomes from Sep 2011 through Mar 2015: 1) High NTMx-exposures per 1000 pt-days 2) AKI episodes per 1000 pt-days 3) AKI rates per exposure case (%) and 4) AKI days per 100 high NTMx-exposure days (intensity). AKI was defined by KDIGO SCr criteria. We used statistical process control charts to assess for changes from baseline rates.

Results: 1,783 patients accounted for 2,358 separate admissions and 3,243 individual episodes of high NTMx exposure. 170 patients (9.7%) had 2+ exposures. We observed two decreases in NTMx-exposure and AKI rates. Overall, the high-NTMx exposure rate decreased by 38% (11.63 to 7.24 admissions/1000 pt-days), and the AKI rate decreased by 64% (2.96 to 1.06 admissions with AKI/1000 pt-days). The NINJA project saved pts from 633 exposure and 398 AKI episodes (when compared to baseline rates). Medications/medication classes or admitting services for exposed or AKI pts did not differ between the 3 months preceding and following either time point improvement. AKI rates per exposure (23.3% to 15.4%) and AKI intensity (27.7 to 19.1 AKI days/100 exposure days) also decreased in Year 1; both improvements persisted for the entire period.

Conclusions: Implementation of systematic surveillance for NTMx-AKI can lead to sustained reductions in avoidable harm.

Funding: Private Foundation Support

FR-PO501

Early and Late Aute Kidney Injury in Severely Burned Patients Stanislaw Niemczyk,[1] Wojciech Witkowski,[2] Wojciech Klimm,[1] Agnieszka Surowiecka- Pastewka,[2] Marek Kawecki,[3,5] Katarzyna Szamotulska.[4] *[1]Dept of Internal Medicine, Nephrology and Dialysotherapy, Military Inst of Medicine, Warsaw, Poland; [2]Dept of Burns, Plastic and Reconstructive Surgery, Military Inst of Medicine, Warsaw, Poland; [3]Dept of Treatment of Burns, Centre for the Treatment of Burns, Siemianowice Slaskie, Poland; [4]Dept of Epidemiology and Biostatistics, Inst of Mother and Child, Warsaw, Poland; [5]Dept of Emergency Medicine, Faculty of Health Sciences, Academy of Technology and Humanities, Bielsko-Biala, Poland.*

Background: Evaluation of factors influencing early and late acute kidney injury (AKI) in severely burned patients and assessment of the relationship between time of occurrence of AKI and mortality.

Methods: Retrospective analysis of severely burned patients with>30%total body surface area (TBSA), admitted to two centers for the treatment of burns. We selected and analysed 239 severely burned patients. Renal function was evaluated at three points: admission, critical or middle point of hospitalization and the endpoint death or discharge from the center. AKI criteria: decrease in glomerular filtration rate (GFR)>60 ml/min at admission, decrease in GFR>75% compared to baseline, decrease in the daily diuresis<500 ml.

Results: At admission 15.1% of the patients had GFR <60 ml/min. AKI occurred in 38.5%. The occurrence of AKI was associated with: elderly age (p<0,001), female gender (p=0,017), overweight and obesity (p=0,055); extentand depth of burns, respiratory failure, low protein concentration (for all p<0,001), low blood pressure (p=0,014) and high white blood cells count (WBC) (p=0,010). Early AKI was detected in 28%. Mortality was 100% with the initial GFR>60ml/min, 100% with the initial GFR <60 ml/min and early deterioration of renal function, 80% with the initial GFR <60 ml/min and late worsening, and 60% with the initial GFR <60 ml/min and no worsening. Late AKI was observed in 10% of patients and mortality was 79.2%. Mortality in the group with AKI was 88.0% versus 24.5% without AKI.

Conclusions: The frequent occurrence of AKI, especially early, worsens the prognosis for survival. The assessment of renal function should be included in the prognostic scales for burned patients.

FR-PO502

Acute Kidney Injury and Risk of Incident Heart Failure Among U.S. Veterans Nisha Bansal,[1] Michael Edwin Matheny,[2] Svetlana Eden,[2] Robert Greevy,[2] Sharidan Parr,[2] James Fly,[2] Khaled Abdel-Kader,[2] Jonathan Himmelfarb,[1] Ian H. De Boer,[1] Talat Alp Ikizler,[2] Edward D. Siew.[2] *[1]UW; [2]Vanderbilt.*

Background: Acute kidney injury (AKI) is common and associated with poor long-term outcomes. Heart failure (HF) is a leading cause of cardiovascular disease among patients with chronic kidney disease (CKD). The relationship between AKI and HF remains unknown and may identify a novel mechanistic link between kidney and cardiovascular disease.

Methods: We studied a national retrospective cohort of 111,488 U.S. Veterans hospitalized between 2003-2012 without history of HF. AKI was defined as a 0.3 mg/dl or 50% increase in serum creatinine using the difference between peak hospitalization and baseline creatinine (as determined by mean outpatient creatinine over previous year) and staged according to Kidney Disease Improving Global Outcomes (KDIGO) criteria using change in serum creatinine. Incident HF was defined as > 1 hospitalization or >2 visits with a diagnosis of HF, as determined from validated ICD9 codes, through 2012. Propensity scores using 37 relevant inpatient and outpatient covariates were generated and patients with and without AKI were matched 1:1. Cox proportional hazards were used to determine the association of AKI with risk of incident HF, adjusting for baseline age, eGFR, coronary heart disease and hypertension. Patients who died or had an outcome after the end of the study were censored.

Results: There were 17,272 matched pairs with and without AKI in the study. Patients with and without AKI during the index hospitalization were well matched with median

age of 66 years and 22% were African-American. Median pre-admission eGFR was 65.6 ml/min/1.73 m2, 37% had diabetes and 72% had hypertension prior to admission. Over a median follow-up time of 41 months, 11% of those without AKI vs. 14% in those with AKI had incident HF. AKI was associated with increased risk of incident HF (adjusted HR=1.3 [95% CI:1.2, 1.4]).

Conclusions: AKI is an independent risk factor for incident HF adding further evidence to the long-term cardiovascular consequences of AKI. Future studies to identify underlying mechanisms, modifiable risk factors, and patients at highest risk for AKI are needed.

FR-PO503

Incidence of Acute Kidney Injury Among Patients with Chronic Kidney Disease: A Single-Center Retrospective Database Analysis Taro Horino,[1] Yutaka Hatakeyama,[2] Hiromi Kataoka,[2] Tatsuki Matsumoto,[1] Kazu Hamada-Ode,[1] Yoshiko Shimamura,[1] Koji Ogata,[1] Kosuke Inoue,[1] Yoshinori Taniguchi,[1] Yoshio Terada,[1] Yoshiyasu Okuhara.[2] *[1]Dept of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Kochi Univ, Nankoku, Japan; [2]Center of Medical Information Science, Kochi Medical School, Kochi Univ, Nankoku, Japan.*

Background: Acute kidney injury (AKI) is a serious complication among hospitalized individuals and is closely associated with chronic kidney disease (CKD).This study investigated the incidences of AKI in the various CKD stages.

Methods: This retrospective cohort study evaluated 125,059 individuals who visited Kochi Medical School hospital between October 19, 1981 and December 31, 2013. AKI was defined and staged according to the Kidney Disease Improving Global Outcomes criteria, using measured serum creatinine levels.

Results: We analyzed data from 122,653 Japanese patients, including 57,105 (46.6%) men. The incidence of AKI in this cohort was 7.8% (95% confidence interval: 7.7–8.0%). Compared to non-AKI patients, patients with stage 1–2 AKI were more likely to be men. Patients with stage 1–2 AKI were significantly older than non-AKI or stage 3 AKI patients. The incidences of AKI were 6.7 %, 5.9%, 10.4%, 18.4%, 30.0%, and 48.8% in individuals with estimated glomerular filtration rates of ≥90, 60–90, 45–60, 30–45, 15–30, and £15 mL/min/1.73 m^2, respectively. These incidences of AKI were significantly different, compared to the incidence for the baseline eGFR.

Conclusions: We found that CKD was a risk factor for AKI, and that the incidence of AKI was positively associated with pre-existing reduced kidney function (stage of CKD). We suggest that outpatients should be monitored for AKI, given its unexpected incidence in that population.

FR-PO504

Acute Kidney Injury in Patients without Atherosclerotic Cardiovascular Disease and Long-Term Risk of Myocardial Infarction, Revascularization, and Death Martin Holzmann,[1] Linda C. Ryden,[1] Ulrik Sartipy.[1] *[1]Karolinska Inst; [2]Karolinska Inst; [3]Karolinska Inst.*

Background: Acute kidney injury (AKI) is associated with death and cardiovascular disease (CVD). Prior studies on AKI have been conducted in populations with established CVD, or in mixed populations. We sought to investigate the association between AKI and risk of coronary artery disease (CAD), and death in patients with no prior history of any atherosclerotic disease.

Methods: All patients who underwent an isolated surgical aortic valve replacement in Sweden 1999-2011 were eligible. Patients with any history of atherosclerotic disease, i.e myocardial infarction, angina, prior revascularization (PCI/CABG), ischemic stroke, peripheral vascular disease, and aortic aneurysm were excluded (n=4230). The primary outcome was myocardial infarction, and/or revascularization, and the secondary outcome all-cause mortality. AKI was defined according to AKIN criteria.

Results: We included 4823 patients (44% women), with a mean age of 67 (13) years. 489 (10%), 73 (1.5%), and 32 (0.7%) patients developed AKI stage 1, 2 and 3, respectively. During a mean of 6.4 (SD 3.5) years (31 009 person-years) in total 151 (3.1%) patients had a myocardial infarction/revascularization, and in total 850 (18%) patients died. Number of CVD events were: 130 (3.1%), 16 (3.3%), and 5 (4.8%); and number of deaths: 694 (16%), 122 (25%), and 34 (32%)in AKI stage 0, 1 and 2-3, respectively. There was no significant association between AKI stage 1 or 2-3 and CVD events: crude HR: 1.13 (95% CI 0.68-1.90), and 1.66 (95% CI 0.68-4.09); adjusted HR: 1.11 (95% CI 0.64-1.91), and 1.59 (95% CI 0.58-4.32) compared with no AKI. There was a significant association between AKI stage 1 or AKI stage 2-3 and all-cause mortality: crude HR: 1.81 (95% CI 1.49-2.20), and 2.60 (95% CI 1.84-3.67); adjusted HR: 1.12 (95% CI 0.92-1.37), and 1.86 (95% CI 1.31-2.65) compared with no AKI.

Conclusions: In a cohort of patients without any established atherosclerotic disease we found no association between AKI and subsequent coronary artery disease. However, patient with AKI stage 2-3 had an almost doubled risk of death during follow-up.

FR-PO505

Acute Kidney Injury Increases Medical Costs Even in the Pre-AKI Stage Jeonghwan Lee,[1] Seon Ha Baek,[2] Shin-Young Ahn,[2] Ho Jun Chin,[2] Ki Young Na,[2] Dong-Wan Chae,[2] Sejoong Kim.[2] *[1]Internal Medicine, Hallym Univ Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam, Gyeonggi-do, Republic of Korea.*

Background: Early detection of acute kidney injury (AKI) is important to prevent the progression of AKI and to improve clinical outcomes. However the significance of mild increase in serum creatinine below AKI stage is not well established. In this study, we defined pre-AKI as the 25-50% increase of serum creatinine levels from the baseline levels. We aimed to investigate the influence of AKI stage including pre-AKI on clinical outcomes.

Methods: All clinical and laboratory data were retrieved from electronic medical record database. We enrolled a total of 20819 patients who admitted Seoul National University Bundang Hospital from January 1, 2013 to December 31, 2013. We excluded patients who had not checked serum creatinine levels during admission or who were on dialysis due to end-stage renal disease.

Results: The proportion of patients who had AKI during admission were 21.6% (pre-AKI), 15.8% (AKI stage 1), 5.9% (AKI stage 2), and 3.2% (AKI stage 3). In-hospital mortality increased according to the stage of AKI [log-rank P < 0.001; HRs 1.878 (1.189-2.966) AKI stage 1; 6.039 (3.948-9.239) AKI stage 2; 12.064 (7.992-18.210) AKI stage 3]. Patients with pre-AKI showed no differences in mortality compared to patients without AKI [HRs 1.180 (0.708-1.966), P = 0.527]. However, patients with pre-AKI were characterized with increased length of stay (no AKI 7.4 ± 9.0 days, pre-AKI 13.0 ± 13.3 days, P < 0.001) and increased medical costs (no AKI: 2806 ± 3286 USD, pre-AKI: 4701 ± 3476 USD, P < 0.001) during admission. Patients with Pre-AKI were more on surgical condition (51.1% vs 34.0%, P < 0.001) compared to patients without AKI.

Conclusions: Patients with pre-AKI stage are associated with longer length of hospital stay and increased medical costs during admission. Clinical significance of pre-AKI should be paid attention.

FR-PO506

Impact of Fluid Overload on Acute Kidney Injury Diagnosis and Associated Outcomes in Critically Ill Patients: A Retrospective Cohort Study Luis Ignacio Bonilla,[1,2] Sara Samoni,[2] Maria Fernanda Golzarri,[1] Salvador Roberto Lopez,[2,3] Jordana S. Lemus,[4] Guillermo Cardenas,[4] Claudio Ronco.[2] *[1]Internal Medicine, Hospital General Dr. Manuel Gea Gonzalez, Mexico City, Mexico; [2]IRRIV, International Renal Research Inst Vicenza, Vicenza, Italy; [3]Nephrology, National Inst of Cardiology, Mexico City, Mexico; [4]ICU, Hospital General Dr. Manuel Gea Gonzalez, Mexico City, Mexico.*

Background: Fluid overload(FO)changes the volume of distribution of creatinine,which is equivalent to total body water(TBW),this can alter the serum creatinine(sCr) concentrations;higher TBW result in lower sCr leading to underestimation of AKI. Adjustment of sCr is done by applying a formula(Adjusted Cr=sCrx[1+(cumulative fluid balance/TBW)]).We hypothesized that in pts with >5%of FO the adjustment of sCr for TBW would diagnose more pts with AKI and diagnose AKI earlier than in pts with <2.5%of FO.

Methods: We made a retrospective analysis of 120 records of pts from 2 centers.We calculated daily fluid balance and divided it by the body weight to obtain a percentage of FO.Pts were divided into 2 groups,A and B,with <2.5%and >5%of FO,respectively. Measured daily sCr was corrected using the TBW formula and presence of AKI was evaluated daily according to KDIGO guidelines.We compared the prevalence,day of diagnosis and associated outcomes between the 2 groups.

Results: Mean age in the cohort was 54.4yrs,56.3% were male.In group A 24(34.8%)of pts were diagnosed with AKI before adjustment and 25(36.2%)after adjustment(p=0.167).In group B 21(48.8%)and 25(58.1%)were diagnosed with AKI before and after adjustment,respectively(p=0.023).Mean detection day of AKI without and with adjustment in group A was 3.22±2.4 and 2.84±2.1,respectively(p>0.001) and in group B 3.4±2.3 and 3±2.2(p>0.001). Mortality in group A was 10.14%and in group B 32.56%(p=0.005).

Conclusions: Correction of measured sCr for TBW in patients with >5%of FO is useful to diagnose more patients with AKI.Usage of the formula demonstrated usefulness for early diagnosis in patients with <2.5%and >5%of FO and we recommend its application in order to improve AKI prevention and treatment.FO of >5%is associated with increased mortality and worse outcomes in critically ill pts.

FR-PO507

Placental Growth Factor (PLGF) Is the Novel Predictor of CKD Progression: The Results from NARA-CKD Study Masaru Matsui, Katsuhiko Morimoto, Miho Tagawa, Ken-ichi Samejima, Yasuhiro Akai, Yoshihiko Saito. *First Dept of Internal Medicine, Nara Medical Univ, Kashihara, Japan.*

Background: PlGF plays a critical role in atherogenesis through vascular inflammation. We have already reported an independent association of PlGF with survival and cardiovascular risk in the patients with chronic kidney disease (CKD) in the Novel Assessment of Risk management for Atherosclerotic diseases in CKD (NARA-CKD) study; however, the relations between circulating levels of PlGF and the progression of CKD remains unknown.

Methods: A prospective cohort study of 402 participants undergoing renal biopsy was conducted to elucidate the predictive value of PlGF on renal prognosis in the patients with CKD.

Results: Histologically, elevated PlGF was significantly associated with the severity of tubulointerstitial damage and the intimal thickening of small renal arteries. During a median follow-up of 2.7 years, 82 patients reached primary end-points which were defined as the requirement of renal replacement therapy (38 patients) and the decline of eGFR by more than 25% from baseline (44 patients). Although baseline eGFR was not statistically different among patients in all PlGF quartiles, the rate of eGFR decline in the patients with the highest PlGF quartile was significantly faster than those with other quartiles. After adjustment of known confounding factors, PlGF was significantly associated with the risk of deterioration of renal function with the adjusted hazard ratio of 1.75 [1.38-2.26]) for each quartile increment of PlGF. The combined use of eGFR and PlGF significantly improved the predictive accuracy for CKD progression compared with eGFR alone (c statistics from 0.689 to 0.772, p<0.001).

Conclusions: Elevated PlGF is a novel and independent predictor of renal prognosis in the patients with CKD.

FR-PO508

Steeper Decline in Renal Function After a Hypertensive Disorder of Pregnancy: A Longitudinal Study Nina Paauw,[1] Anne Marijn van der Graaf,[2] Rita Bozoglan,[2] David P. van der Ham,[3] Gerjan Navis,[2] Ron T. Gansevoort,[2] Henk Groen,[4] Titia Lely.[1] *[1]Obstetrics, UMC Utrecht, Netherlands; [2]Nefrology, UMC Groningen, Netherlands; [3]Obstetrics, Martini Hospital, Netherlands; [4]Epidemiology, UMC Groningen, Netherlands.*

Background: Hypertensive disorders of pregnancy (HDP) occur in 10% of pregnancies. Population based studies report increased risk for ESRD after HDP. Longitudinal renal function after HDP has not been studied. Our aim was to longitudinally assess renal function and occurrence of CKD in women after HDP compared to controls.

Methods: Data from the PREVEND study, a population based prospective cohort with median follow-up of 11 years, were used to identify women without and with self-reported HDP (non-HDP, n=1805 and HDP, n=977). A case cohort, 10 years post-partum was created by record linkage, with subgroups: normal pregnancy (control, n=202), pregnancy-induced hypertension (PIH, n=56) and preeclampsia (PE, n=29). Renal function and the prevalence of CKD were compared.

Results: eGFR was lower at baseline and during follow-up in HDP vs non-HDP **(A)**. In addition, the decline in eGFR was steeper in HDP vs non-HDP **(B)**. At baseline and during follow-up there was more anti-hypertensive-drug use, including ACEi in the HDP group. 24-h albuminuria at baseline was higher in HDP vs non-HDP and remained steadily higher in HDP during follow-up. A trend towards increased risk of CKD was observed in HDP; HR 1.13 (0.92-1.38). In the case cohort, eGFR was significantly lower **(C)** and 24-h albuminuria significantly higher (p=0.03) in the PE vs controls. 7.8% of the controls, 10.9% of the PIH and 19.2% of the PE group met the criteria for CKD.

Conclusions: We report a lower renal function and a steeper renal function decline over time after HDP. Women with severe hypertensive disorders of pregnancy (PE) have the highest risk for renal function loss.

Pregnancy Outcomes in Women with Chronic Kidney Disease in South Australia Shilpa Jesudason,[1,3] Alyssa Kate Fitzpatrick,[4] Britt Melinda Catcheside,[2] Wendy Katharine Scheil,[2] Stephen P. McDonald.[1,3] *[1]Central and Northern Adelaide Renal and Transplantation Services, Adelaide, Australia; [2]South Australian Pregnancy Outcomes Unit, Adelaide, Australia; [3]School of Medicine, Univ of Adelaide, Adelaide, Australia; [4]Univ of Oxford, Oxford, United Kingdom.*

Background: Chronic kidney disease (CKD) affects an estimated 3% of women in their childbearing years. CKD in pregnancy is associated with adverse maternal and neonatal outcomes. This study represents the first attempt to capture the distribution of CKD among pregnant women in the Australian context.

Methods: Data was obtained from the South Australian Pregnancy Outcomes Unit Supplementary Birth Record for singleton pregnancies from 1990-2012. Women with CKD were identified by renal ICD-9 codes for immunological renal conditions, cystic/genetic renal disease, vesicoureteral reflux, hypertensive CKD, urological conditions, pyelonephritis, and unspecified renal disease. Uncomplicated urinary tract infections were excluded. Data was obtained on maternal demographics, obstetric care and infant outcomes. Chi-squared or Fisher's exact tests were used to examine the crude association between renal disease and adverse outcomes.

Results: 1392 births to women with renal disease codes were identified from 407,580 recorded births. Women with renal disease were significantly more likely to be Aboriginal (5.2% vs 2.6%, p<0.001), to have the lowest socioeconomic status (31.4% vs 26.2%, p<0.001) and to smoke (24.1% vs 18.4%, p<0.001). Higher unadjusted risks of adverse outcomes were noted in the renal group, including gestational hypertension (10.6% vs 5.0%, p<0.001) and emergency caesarean section (20.0% vs 15.0%, p<0.001). Women with renal disease were more likely to have a preterm birth <34 weeks (6.7% vs 2.1%, p<0.001), or a late preterm birth 34-36 weeks (10.8% vs 4.5%, p<0.001). They were also more likely to be diagnosed with intrauterine growth restriction (11.2% vs 9.5%, p=0.03) and to deliver a low birth weight baby <2500g (13.4% vs 5.5%, p<0.001).

Conclusions: Indigenous Australian women and women with low socioeconomic status are disproportionately burdened by CKD in pregnancy. The data showed increased adverse maternal and neonatal outcomes among women with CKD.

FR-PO510

Identification of Renal Disease in Women with Hypertensive Pregnancies Kate Bramham, Katherine R. Clark, Daniel Stott, Daniela Paraschiv, Nicholas Kametas. *Antenatal Hypertension Clinic, King's College Hospital, London, United Kingdom.*

Background: Hypertension in pregnancy can be associated with renal injury which may be masked by gestational change. Postpartum assessment is an opportunity to detect persistent renal abnormalities. However previous studies are small and often exclude those with pre-existing hypertension, a risk factor for CKD. Aim: To determine the postpartum prevalence of renal abnormalities in women with chronic hypertension, pregnancy induced hypertension (PIH) or pre-eclampsia (PE) in a previous or current pregnancy.

Methods: Women with singleton pregnancies referred to a hypertension pregnancy clinic (Feb 2011-Nov 2014) attending postpartum review (offered to all) were included. Those with previously diagnosed CKD were excluded. Demographics, 24 hour urine protein, estimated GFR (CKD-EPI) and blood pressure after six weeks postpartum were recorded.

Results: Overall 120 (29.7%) of women were found to have features of renal disease postpartum. Subgroup analysis according to hypertensive groups is shown in Table 1.

	Chronic Hypertensive (N=115)	History of PE/PIH (N=102)	PE/PIH in current pregnancy (N=187)
Body mass index, Kg/m²	31.7 (7.4)	28.7 (6.9) †	27.2 (5.3) †
Maternal age, years	35.8 (5.1)	34.1 (4.9)	32.3 (5.6) † §
Postnatal visit – weeks from delivery	7.2 (1.7)	7.6 (2.5)	7.2 (1.6)
Systolic blood pressure mmHg	137.4 (14.2)	128.2 (18.0) †	126.7 (14.2) †
Diastolic blood pressure mmHg	87.2 (9.2)	81.1 (11.7) †	80.2 (10.0) †
Normal renal function n (%)	72 (62.6)	131 (70.0)	81 (79.4)
Proteinuria≥150mg/24h & eGFR>90ml/min n (%)	22 (19.1)	30 (29.4)	11 (5.8)
Proteinuria<150mg/24h & eGFR<90 ml/min n (%)	17 (14.7)	22 (11.7)	9 (8.8)
Proteinuria>150mg/24h & eGFR <90ml/min n (%)	4 (3.5)	4 (4.0)	1 (0.5)

PE:Pre-eclampsia; PIH: Pregnancy induced hypertension † P<0.001 Compared with chronic hypertension. § P<0.001 Compared with history of PE/PIH.

Conclusions: A substantial proportion of women with hypertension in pregnancy have renal abnormalities after six weeks postpartum. Identification of risk factors for progression of CKD in this population through longitudinal studies is needed.

FR-PO511

Changes of Markers of Prothrombotic State in Membranous Nephropathy Complicated with Type 2 Diabetes Yuanmeng Jin. *Nephrology, Ruijin Hospital, Shanghai Jiao Tong Univ School of Medicine, Shanghai, China.*

Background: Membranous nephropathy (MN) complicated with type 2 diabetes showed high incidence of thrombosis, which was related to abnormity of prothrombotic state. This investigation was designed to explore changes of prothrombotic state and mechanism of thrombosis in MN complicated with type 2 diabetes.

Methods: We enrolled total 30 patients with nephrotic syndrome (NS), 12 patients were pure MN, 6 patients were diabetic kidney disease (DKD), 12 patients were MN complicated with type 2 diabetes (MN+DM). All patients were diagnosed by renal biopsy. 14 healthy people were enrolled for normal control. The markers for prothrombotic state, including endothelial function (vWF, AngiotensinII), coagulation function (Protein C, Protein S, Antithrombin III, Thromboelastogram index), fibrinolytic function (Fibrinogen, Fibrinogen degradation product, D-D dimer) were tested.

Results: Compared to CKD group, vWF levels in MN and DKD group were higher, but was significantly higher in MN+DM group. Protein C and thromboelastogram index in MN+DM group were higher than control, which were not significantly changed in MN and DKD group. Fibrinogen levels in both MN+DM and MN group were higher than others, and D-D dimer levels were especially higher in MN+DM group, even compared to MN group. There were no changes of other marks in four groups.

Conclusions: Under NS state, MN+DM patients existed more serious prothrombotic state, compared to pure MN and DKD. The mechanism is related to disorders of endothelial function, coagulation function, as well as fibrinolytic function. More attention should be paid to treatment of prothrombotic statein MN+DM patients.

Serum C3 and Renal Outcome in Patients with Primary Focal Segmental Glomerulosclerosis Jian Liu, Jingyuan Xie, Jun Tong, Hong Ren, Weiming Wang, Nan Chen. *Dept of Nephrology, Rui Jin Hospital, Shanghai Jiao Tong Univ, School of Medicine, Shanghai, China.*

Background: The role of complement in the pathogenesis or progression of FSGS is uncertain. The aim of this observational cohort study was to identify the clinical implications of serum C3 levels and to investigate their utility as predictor of renal outcomes in patients with FSGS.

Methods: 591 biopsy-proven primary FSGS patients were recruited. Clinical, histological and progression data were recorded. Decreased serum C3 level was defined as C3 <85 mg/dl. The study endpoint was end-stage renal disease (ESRD).

Results: Of the patients, there were 117 patients (25.1%) with low serum C3. At the time-point of renal biopsy, compared to patients with C3 ≥85 mg/dl, those with C3 <85 mg/dl had higher level of serum creatinine, lower levels of eGFR, proteinuria, hemoglobin, triglyceride, cholesterol, IgA, more severe segmental sclerosis, tubular atrophy and interstitial fibrosis. Multivariate linear regression analysis showed low C3 level was an independent risk factor for eGFR (HR=42.56, 95%CI 11.21- 73.91, p<0.01) after adjusted by sex, age and clinical indicators. The follow-up was assessed in 221 patients. During a mean follow-up of 53.3 months, ESRD occurred in 32 patients (37.2%) with low serum C3 compared with 22 patients (16.3%) with normal C3 levels (P <0.001). Serum C3 level had a significant predictive value for renal outcome (AUC = 0.650, P = 0.001), The risk of reaching ESRD was significantly higher in patients with low serum C3 level (HR 4.044; 95% CI= 2.238 to 7.309; P < 0.0001).

Conclusions: Complement activation may occur in patients with FSGS. It is associated with clinical and histological severities. Low serum C3 is an independent risk factor for the decline of eGFR, and is associated with poor renal outcome in patients with FSGS.

FR-PO513

Role of Proteolytic Fragment suPAR D2-D3 in Prediction and Cause of FSGS Sanja Sever,[1] Marina V. Kasaikina,[1] Eileen Kapples,[1] Jian Cai,[2] Jon B. Klein,[2] Nada Alachkar,[3] Changli Wei,[4] Changkyu Gu,[1] Jochen Reiser.[4] *[1]Nephrology, Massachusetts General Hospital, Charlestown, MA; [2]Univ of Louisville School of Medicine, Louisville, KY; [3]Nephrology, Johns Hopkins Univ School of Medicine, Baltimore, MD; [4]Medicine, Rush Univ Medical Center, Chicago, IL.*

Background: Primary FSGS is a kidney disorder that leads to end stage renal disease and affects tens of thousands people annually. Several studies suggest the soluble urokinase-type plasminogen activating receptor (suPAR) to be a predisposing circulating factor and prognostic marker of FSGS through its interaction with avb3 integrin.

Methods: We collected serum samples from kidney transplant recipients with FSGS. We also analyzed sera from healthy controls and patients with sepsis and on peritoneal dialysis. These sera were used to assess integrin activation in podocytes. Western blot was utilized to identify full length and D2-D3 fragment of suPAR. Transgenic mice were created to drive mouse suPAR D1-D2-D3 and suPAR D2-D3 expression from adipocytes and consequent release into circulation.

Results: We found that multiple disorders, including FSGS, sepsis, and peritoneal dialysis, are associated with an increase in bulk serum suPAR levels; however, only a subset of sera from FSGS patients induced integrin activation in podocytes. Western blot identified a fragment of suPAR (containing the D2-D3) only in the subset of sera from patients with recurrent FSGS. In vitro, the EC50 response of D2-D3 for activating integrin avb3 was approximately ten fold than for D1-D2-D3. Exposure of podocytes to physiological concentrations of the D2-D3 increased the amount of surface uPAR and facilitated podocyte motility. Injections of the D2-D3, but not full-length suPAR, induced transient proteinuria in mice. Transgenic mice for D2-D3 developed rising serum suPAR levels and a variable degree of proteinuria. A composite risk analysis score was developed that included presence of the D2-D3 in patient serum, podocyte integrin activation capacity, and total suPAR serum level for the prediction of recurrent FSGS.

Conclusions: suPAR D2-D3 fragment is a prognostic marker and risk factor for recurrent FSGS.

FR-PO514

Prognosis, Survival and Renal Function in Patients with Lupus Nephritis Gustavo Aroca Martinez,[1,2] Andres A. Cadena,[2] Eduardo Egea Bermejo,[4] Jossie E. Fontalvo,[1] Yeneris Gaviria,[1] Henry J. Gonzalez Torres,[1] Moises A. Arquez Mendoza,[1] José Rafael Consuegra,[1] Santos Depine.[1] *[1]Medicine, Univ Simon Bolivar, Barranquilla, Atlantico, Colombia; [2]Nephrology, Clinica de la Costa, Barranquilla, Atlantico, Colombia; [3]Medicine, Univ Nacional de Colombia, Colombia, Atlantico, Colombia; [4]Medicine, Univ del Norte, Colombia, Atlantico, Colombia.*

Background: Lupus nephritis is the most common glomerulonephritis in the Colombian Caribbean region, despite there is less published information about its evolution and clínico-pathotogical aspects. **Objective**: To evaluate prognosis, survival and renal function of patients with LN residing in the Colombian Caribbean region controlled between 2008 - -2014.

Methods: 229 patient study with LN corroborated by histology according to the International Society of Nephrology Clasification /Renal Pathology Society (ISN/ RPS. 2003) treated with induction and maintenance therapy and with a systemized following of at least 2 years. The pharmacological treatments included prednisolone, azathioprine, and Cyclophosphamide mycophenolate mofetil in isolation or combined and the clinical laboratory and histopathology variables were correlated as predictive value of therapeutic response. To achieve this as methodology a non-parametric descriptive statistics ANOVA (k-w) was used and canonical correspondence analysis.

Results: 229 patients in total of 34±12 of age, which 88% women, whose evolution were controlled during 24±6 months. The most common form of clinical presentation was nephrotic syndrome and asymptomatic hematuria-proteinuria (68.07%) the type III and IV of LN (84,23%) were associated with patients under 25 of age and a negative response to treatment. The estimated glomerular filtration rate measured by MDRD4 showed a significant improvement at 24 weeks with regard the baseline figure of 74,36.

Conclusions: The early detection and reference of NL patients allows an early approach and therapy. Which will prevent chronic kidney disease.

FR-PO515

Association of ABO Blood Group with Progression of IgA Nephropathy Meng Yang, Jingyuan Xie, Yan Ouyang, Xiaoyan Zhang, Xiao Li, Wen Zhang, Weiming Wang, Nan Chen. *Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.*

Background: ABO blood group antigens are major histocompatibility antigens and little is known about its association with progression of IgA nephropathy (IgAN).

Methods: Biopsy-proven primary IgAN patients were retrospectively recruited. Clinical, histological and progression data were recorded. Patients with eGFR<15ml•min^{-1}•(1.73m^2)$^{-1}$ at time of biopsy were excluded. Renal tissue was semi-quantitative scoredaccording to the Oxford scoring system. ABO blood group was determined by standard erythrocyte antiserum agglutination method. All patients were divided into B antigen group (type B and AB) and non-B antigen group (type A and O) based on their ABO types.

Results: Among the 752 IgAN patients recruited in this study, 210 patients were type A (27.9%), 221 were type B (29.4%), 72 were type AB (9.6%) and 249 were type O (33.1%). When renal biopsy was performed, patients in B antigen group had higher eGFR (82.44 vs. 65.68 ml/min), lower systolic blood pressure (sbp) (125.36 vs. 129.29 mmHg) and uric acid (373.59 vs. 393.93 mmol/l) than patients in non-B antigen group. No significant difference was detected between histological lesions and these two groups. Totally, 100 patients progressed to end-stage renal disease (ESRD) after a median follow-up period of 51.05 months, including 32 (15.2%) type A, 18 (8.1%) type B, 2 (2.8%) type AB and 48 (19.3%) type O patients. Kaplan-Meier analysis showed that median ESRD-free survival time of patients in B antigen group was significantly longer than patients in no-B antigen group [148.2±5.5 months vs. 138.8±7.5 months, p<0.001]. Furthermore, patients in B antigen group were associated with a decreased risk of ESRD (HR=0.56, 95%CI 0.33-0.94) after adjusted by age, sex and clinical variables including eGFR, sbp, serum albumin, urine protein and hemoglobin by Cox proportional hazards model.

Conclusions: Our data suggested that B antigen had an independent protective effect against the progression of IgAN.

FR-PO516

The Analysis of the Long-Term Outcomes of Patients with Primary IgA Nephropathy Hao Li, Jian Liu, Wei Huang, Pingyan Shen, Zhaohui Wang, Ya Li, Xiaoxia Pan, Jingyuan Xie, Weiming Wang, Nan Chen. *Dept of Nephrology, Shanghai Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.*

Background: Primary IgA nephropathy (IgAN) is one of the most common glomerular diseases in China. In this study we try to investigate the clinical characteristics and the relationship between CKD stages and long-term outcomes of patients with primary IgAN through the retrospective analysis of their clinical data.

Methods: Patients with biopsy-proved primary IgAN from 2002 to 2013 were included in the retrospective analysis. They were older than 18 years old and their follow-up time was more than 12 months. We collected their medical history, laboratory test reports and other clinical data. Then we enrolled 297 patients who were followed up for 5 years for further research. Kaplan-Meier method was used to calculate the renal survival rate of the patients.

Results: A total of 1052 cases were included. There is an equal proportion of male and female(50.4% vs 49.6%). The mean age was 36.86±11.58 years old. Five-year renal survival rate of these cases was 92%, and ten-year renal survival rate was 88%. We enrolled 297 cases who were followed up for 5 years. These patients were divided into rapid progression and stable progression, we found that cases in rapid progression group had more proteinuria, higher blood pressure, poorer renal function , lower serum albumin and lower hemoglobin, compared with other groups. When cases were divided according to CKD stages, the results showed no significant difference of outcomes among patients in CKD1-3a stage ($P > 0.05$). Their five-year renal survival rate was more than 95%. But patients in CKD3b-4 stage had worse outcomes. The five-year renal survival rate of patients in CKD3b stage was 85.3%, while it is only 65.3% for patients in CKD4 stage.

Conclusions: Five-year and ten-year renal survival rate of patients with IgAN was 92% and 88%, respectively. Patients in CKD3b or CKD4 stage at biopsy may have a lower renal survival rate and a worse outcome. At the time of renal biopsy, patients with impaired renal function, mass proteinuria, hypertension, anemia and low serum albumin may have a greater risk of progressing to end-stage renal disease .

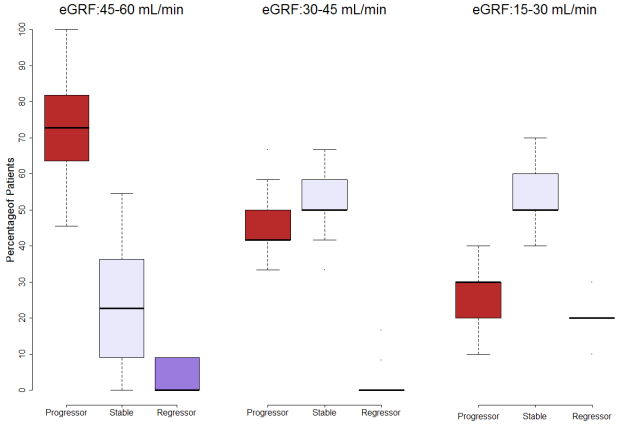
FR-PO517

Variability of GFR Decline in Alport Syndrome: Insights from a Provincial Database David Langsford,[1] Mila Tang,[2] Ognjenka Djurdjev,[3] Lee Er,[3] Adeera Levin.[1,3] *[1]UBC; [2]BC Renal Agency.*

Background: Alport syndrome (AS) is one of the inherited causes of CKD due to mutations in the collagen genes making up the glomerular basement membrane collagen. Design of clinical trials for intervention in AS proves challenging without a clear understanding of renal progression over time as observational data is lacking due to small sample size. We present here the utilization of population based data in a simulation to mimic clinical trial recruitment and endpoints to provide insights in trials design for AS.

Methods: AS patients were identified within a provincial CKD clinical database (PROMIS) in British Columbia, Canada for this observational simulation study. Patients were excluded if they have fewer than 4 eGFR-MDRD measurements or 2 as a study entry point to generate 100 random samples. Primary outcome was annual rate of eGFR change over 2 years categorized into: > -5 mL/min per year (progressor), -5 and 2 mL/min per year (stable), >2 mL/min year (regressor).

Results: 37 pts met inclusion criteria; median follow-up was 48.2 months, and median age of 36. The sample sizes for each random sample at the 3 enrolment eGFR levels were: 11, 12 and 10 respectively. Of those that 'enrolled' at eGFR 45-60 mL/min, 72.7% (IQR:63.6%,81.8%) progressed, and 22.7% (IQR:9.1%, 36.4%) remained in stable state.



For those recruited at eGFR 30-45 mL/min, 41.7% (IQR:41.7%,50%) had disease progression and 50% (IQR:50%, 58.3%) remained in stable state. Of those enrolled at eGFR 15-30 mL/min, 50% (IQR:50%,60%) were in stable state, 30.0% (IQR:20%, 30%) had disease progression, and 20% (IQR:20%,20%) had an improvement in eGFR.

Conclusions: Heterogeneity and non-linearity of AS renal progression ought to be taken into account when designing trials of interventions aimed at improving renal outcomes.

FR-PO518

Discovery of Urine MicroRNA Biomarkers in a Pre-Clinical Model of Alport Nephropathy Martin Beaulieu,[1] Shirley Phillips,[1] Vivek Kaimal,[2] Shweta Pandya,[2] Nelson Chau,[2] Adam Pavlicek,[2] Steven Lockton,[1] Deidre Mackenna,[2] Neil W. Gibson.[2] *[1]microMarkers, Regulus Therapeutics, San Diego, CA; [2]R&D, Regulus Therapeutics, San Diego, CA.*

Background: MicroRNAs (miRs) are a class of short (~23 nucleotide), highly conserved non-coding RNA that inhibit translation and facilitate degradation of messenger RNA (mRNA). MiRs are stable in biological samples and their levels can be deregulated in cells undergoing pathophysiological stress. We developed a miR profiling platform to discover novel biomarkers in bio-fluids. In this study, we aimed to profile miRs in urine, serum and kidney tissue from a pre-clinical model of Alport nephropathy in order to identify microRNA biomarkers with the ability to reflect disease progression.

Methods: Urine from 19 Col4a3$^{-/-}$ mice (SV129 background) and 21 wild type litter mates was collected in metabolic cages over 22 hrs at 4, 6 and 8 weeks of age. The animals were sacrificed at week 8 to obtain kidney tissue and serum samples. Traditional markers of disease progression including blood urea nitrogen (BUN) and urinary microalbuminuria were measured using an Alera Clinical Chemistry analyzer. Following miR extraction, miR profiling was executed on a high-throughput, RT qPCR based system that reproducibly quantifies over 750 miRNAs.

Results: We identified miRs differentially expressed in the kidney (213), serum (60) and urine (67) of the Col4a3$^{-/-}$ mice (FDR adjusted p-value < 0.05). Changes in miR expression in kidney were similar to other renal fibrosis models (e.g. increases in miR-21) reflecting the similarity in pathogenesis across disease models. A urine miR classifier was able to detect the Col4a3$^{-/-}$ mice with 100% accuracy as early as 4 weeks of age.

Conclusions: We have developed a high-throughput, multiplex miR profiling platform with the capacity to profile tissues and bio-fluids. We discovered several urine microRNAs with highly significant differential expression in the Col4a3$^{-/-}$ mouse model when compared to wild type mice. Our data suggest that urine is a favorable bio-fluid for the development of non-invasive microRNA based tests.

FR-PO519

Micrornas as Predictive Biomarkers of Chronic Kidney Disease (CKD) in Patients (Pts) Undergoing Radical Nephrectomy (RN) for Kidney Cancer Francesco Trevisani,[1] Michele Ghidini,[1] Jens C. Hahne,[1] Andrea Lampis,[1] Paolo Manunta,[2] Maria Teresa Sciarrone Alibrandi,[2] Giacomo Dell'Antonio,[2] Lorena Citterio,[2] Laura Zagato,[2] Francesco Montorsi,[2] Fabio Benigni,[2] Alberto Briganti,[2] Roberto Bertini,[2] Andrea Salonia,[2] Cristina Carenzi,[2] Matteo Fassan,[3] Massimo Rugge,[3] Paolo Rigotti,[3] Giovambattista Capasso,[4] Luciano Cascione,[5] Chiara Braconi,[1] Nicola Valeri.[1] *[1]ICR, London, United Kingdom; [2]San Raffaele Inst, Milan, Italy; [3]Univ of Padua, Padua, Italy; [4]Univ of Naples, Naples, Italy; [5]IOR, Bellinzona, Switzerland.*

Background: MicroRNAs(miRs) are small non-coding RNAs involved in cell homeostasis and disease. Our study identified clinical and molecular markers associated with increased risk of developing CKD after RN for renal clear cell carcinoma(RCC).

Methods: 80 pts who underwent RN for RCC at a single institution between 2008-2013 were included. Inclusion criteria: normal renal function at surgery time(eGFR > 60 ml/min CKD-EPI formula 2009, serum creatinine < 1.1 mg/dl, no proteinuria). No pre-existing glomerulopathy. No evidence of metastatic disease. Minimum follow-up:12 months post-surgery. FFPE normal adjacent tissue to RCC(>3cm) was micro-dissected to isolate cortex(10 glomeruli) and medulla and was subject to RNA extraction. miRs analysis was performed using Nanostring nCounter and validated by Real-Time, digital droplet PCR and in situ hybridization(ISH). Cox regression analyses were used to define variables associated with increased risk of CKD.

Results: 47.4% of pts developed CKD(stage 3a-3b-4 KDIGO) 12 months after RN. At multivariable Cox Regression, type II diabetes(pvalue:0.009),basal serum creatinine(pvalue:0.002) and miR-193b over-expression(pvalue:0.017) were independently associated with increased risk of CKD. ISH showed miR-193b over-expression in the tubular-interstitial compartment associated with abnormalities in keeping with early inflammatory and fibrotic changes. MiR-193b detection in matched urine samples is ongoing.

Conclusions: Tissue and urinary miRs deregulation may represent an early marker of kidney dysfunction and may anticipate clinical and laboratory evidence of CKD providing an important tool for personalized follow-up and prevention in pts undergoing RN for RCC.

Urinary Angiotensinogen to Creatinine Ratio Is a Specific Biomarker for Renal Progression in Autosomal Dominant Polycystic Kidney Disease Hayne C. Park,[1] Hyunjin Ryu,[2] Miyeun Han,[2] Hyun Suk Kim,[2] Kook-Hwan Oh,[2] Young-Hwan Hwang,[3] Curie Ahn.[2] *[1]Internal Medicine, Armed Forces Capital Hospital, Seongnam-Si, Gyeonggi-Do, Korea; [2]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [3]Internal Medicine, Eulji General Hospital, Seoul, Korea.*

Background: Urinary angiotensinogen to creatinine ratio (AGT/Cr) is elevated in autosomal dominant polycystic kidney disease (ADPKD), but whether AGT/Cr is a specific biomarker of ADPKD progression is not known. This study was performed to measure urinary AGT/Cr in subcohorts according to primary renal disease (glomerulonephritis (GN), diabetic nephropathy (DN), hypertensive nephropathy (HTN), ADPKD) and to demonstrate its usefulness as a specific biomarker in ADPKD.

Methods: Nine nephrology centers recruited adult subjects with chronic kidney disease (CKD) and classified into subgroups according to primary renal disease. First-voided morning urine was collected from all patients upon enrollment and stored at -80°C until measurement. Urinary AGT was measured by commercial sandwich enzyme-linked immunosorbent assay (ELISA). Urinary AGT/Cr levels and associated factors were compared among CKD subgroups.

Results: A total of 1528 patients were enrolled in KNOW-CKD cohort study (NCT 01630486)from Apr 2011 to Dec 2013. Among them, 153 patients were excluded (73 unclassified subgroups, 71 without urinary AGT measurement, 9 without available eGFR) and a total of 1375 (519 GN, 310 DN, 292 HTN, 254 ADPKD) patients were included in the final analysis. The mean age was 53 years and baseline serum creatinine was 1.9 ± 1.2 mg/dL. The GN and ADPKD subgroups showed younger age and earlier elevation

of urinary AGT/Cr levels according to CKD stages. When we performed the risk factor analysis seperately in GN and ADPKD subgroups, the highest quartile of urinary AGT/Cr was associated with GN subcohort, female gender, hypertension, decreased eGFR, decreased plasma Hb, and higher degree of albuminuria. However, in multivariate logistic regression analysis, ADPKD subcohort demonstrated higher urinary AGT/Cr compared to GN subcohort after adjusting other co-factors.

Conclusions: Urinary AGT/Cr is greatly increased in ADPKD independent of albuminuria and renal function.

Using Biomarkers to Predict Progression to End-Stage Renal Disease within 6 Months of Liver Transplant Joseph T. Bahng,[1] Kimberly Autumn Forde,[1] Peter Abt,[1] Michael R. Bennett,[2] Anirban Ganguli,[1] Mary Ann C. Lim,[1] Debra J. Mccorriston,[1] Mary C. Shaw,[1] Deirdre L. Sawinski.[1] *[1]Perelman School of Medicine at the U. of Pennsylvania; [2]Cincinnati Children's Hospital.*

Background: Liver transplant (LT) recipients are at increased risk for CKD and progression to ESRD. Creatinine, the standard for assessing renal function, provides limited prognostic information for recovery from AKI. Our aim is to create a predictive model for progression to ESRD within 6mos of LT incorporating clinical data and biomarkers.

Methods: We enrolled 202 patients, of whom 138 have 6mos follow up. 13 patients progressed to ESRD, defined as GFR<20 ml/min, dialysis, or transplant evaluation. Logistic regression models evaluated neutrophil gelatinase-associated lipocalin, IL-18, Cystatin-C, Kidney Injury Molecule-1, & liver fatty acid binding protein for inclusion. Receiver operating characteristic curves and concordance statistics were used to assess the models.

Results: In one model, MELD score at LT, pre-LT AKI, pre-LT renal replacement therapy, & highest creatinine 3mos pre-LT were associated with ESRD at 6mos (p<.05). In another model with biomarkers, only urinary IL-18 was included for its association with ESRD (p=.2). The C-statistics for both models were similar (C=0.80 and 0.82, respectively).

Recipient Characteristics	COHORT n = 138	ESRD n = 13	NO ESRD n = 125	p-value
Age *Median (IQR)*	59 (54, 64)	60 (46, 64)	59 (54, 64)	.94
Male Sex *n (%)*	92 (69.2)	6 (54.6)	86 (70.5)	.31
Race *n (%)*				
Caucasian	99 (71.7)	8 (61.5)	91 (72.8)	.39
African American	25 (18.1)	4 (30.8)	21 (16.8)	
Other	14 (10.1)	1 (7.7)	13 (10.4)	
Hepatitis C *n (%)*	71 (51.8)	8 (61.5)	63 (50.8)	.80
Diabetes Mellitus *n (%)*	46 (33.6)	2 (16.7)	44 (35.0)	.34
Hypertension *n (%)*	53 (40.2)	4 (33.3)	49 (39.2)	.77
Highest Creatinine 3Mos Pre-transplant *median (IQR)*	1.49 (1.03, 2.95)	4.37 (2.34, 5.45)	1.4 (1.01, 2.71)	.001
MELD at LT *median (IQR)*	28 (22, 35)	36.5 (31, 44)	28 (22, 34)	.01
AKI Pre-LT *n (%)*	64 (49.2)	10 (83.3)	54 (45.8)	.02
Renal Replacement Therapy Pre-LT *n (%)*	15 (11.0)	6 (50.0)	9 (7.2)	<.01

Conclusions: Biomarkers did not significantly improve ESRD prediction over clinical characteristics. The overall event rate was low and longer follow up may be needed.

FR-PO522

Detection of Inflammatory BioMarkers in Urine Using a Dried, Shelf Stable Transport Device, ViveST™ Daniel R. Mcclernon,[1] Timothy W. Murray,[2] Anita M. Mcclernon.[1] *[1]bioMONTR Labs, Research Triangle Park, NC; [2]Vivebio LLC, Alpharetta, GA.*

Background: Current medical practice assesses health of implanted kidney by monitoring non-specific signals (serum creatinine) after rejection has started and gold standard diagnostic method is invasive kidney biopsy. Studies of non-invasive biomarkers (CXCL9) have shown utility (CTOT-01) in identifying subsets of patients at risk for acute rejection. A urine based test for post surgical evaluations to pinpoint rejection and expedite therapeutic intervention is needed. Here we describe detection of CXCL9/MIG and CXCL10/IP-10 in urine in combination with a novel collection device ViveST, eliminating need for cold chain transport and storage.

Methods: Urine collected and centrifuged (4°C)@2,000xg (30 min). Supernatant decanted into clean tubes and diluted 1:1 with proprietary diluent buffer. Recombinant Human CXCL9/MIG and CXCL10/IP-10 (R&D Systems) was reconstituted using molecular grade water to concentrations of 10,000pg/uL and serially diluted. Urine was spiked with diluted recombinant human MIG or IP-10. 1mL aliquots were loaded onto ViveST and dried. ViveST samples were reconstituted with 1mL of molecular grade water and analyzed concurrently with frozen aliquots using quantitative sandwich enzyme immunoassay techniques specific for MIG or IP-10. Linear regression analysis from seven levels of calibration standard used to calculate MIG and IP-10 concentration.

Results: ViveST samples yielded MIG or IP-10 concentrations similar to corresponding frozen aliquots (see table). Replicate aliquots gave similar results.

Level	MIG (pg/uL)		IP-10 (pg/ul)			
			Male Urine		Female Urine	
	ViveST (n=3)	Frozen (n=1)	ViveST (n=2)	Frozen (n=2)	ViveST (n=2)	Frozen (n=2)
1	117	98	>1572	>1572	>1572	>1572
2	67	53	>1572	>15772	>1572	>1572
3	34	27	1534	1472	1541	1501
4	14	11	1096	1029	1157	1042
5	5	2	Not included in Experiment			
6	0	2				
7	0	0				

Conclusions: MIG and IP-10 can be detected in urine as inflammatory biomarker to assess risk of transplant rejection. ViveST can be used as ambient storage and transport device eliminating need for cold chain storage. Additional studies warranted assessing detection of biomarkers at therapeutically relevant concentrations.

FR-PO523

Albuminuria-Induced Apoptosis in Children with Nephrotic Syndrome Is a Result of the Dysbalance in Apoptosis Controlling System Ievgeniia Burlaka. *Dept of Pediatrics No.4, National O.O. Bogomolets Medical Univ, Kyiv, Ukraine.*

Background: Albuminuria promotes cell death, and is associated with faster progression of chronic kidney disease (CKD). However, the molecular mechanisms regulating cell death in response to albuminuria are not fully understood.

Methods: 53 patients aged 10-15 years with active stage of nephrotic syndrome were included to the study. Immunohistochemical examination of pro-apoptotic factor Bax, anti-apoptotic factor Bcl-xL, number of apoptotic cells in kidney biopsy specimens were done. Comparison of the level of these parameters between the different segments of nephron at different stages of glomerulosclerosis has been performed.

Results: Measurement of the pro-apoptotic factor Bax in kidney slices obtained from children with morphological form of nephrotic syndrome focal segmental glomerulosclerosis (FSGS) showedthe presence of high level of Bax in both glomerular and tubule-interstitial segments. Higher immunosignal of Bax was evaluated in glomeruli with FSGS I-II st. as compared to tubular segment. When FSGS III-IV st. observed higher expression of Bax was detected in surrounding tubule-interstitial segment. Expression of the anti-apoptotic factor Bcl-xL was studied. Higher expression of Bcl-xL was recorded in tubule-interstitial segment as compared to glomeruli when FSGS I-II st. occurs. When FSGS III-IV st.occurshigher immunosignal of Bcl-xL is localized in surrounding tubule-interstitial segment with almost complete absence in glomeruli. The number of apoptotic cells was analysed. Quantitative analysis of apoptosis in kidney sections of patients with FSGS I-II st. revealed higher apoptotic index (AI) in glomeruli as compared to tubule-interstitial component. In kidney sections with FSGS III-IV st. higher AI was found in tubule-interstitial compartment.

Conclusions: Thus, progression of kidney injuries in nephrotic syndrome is associated with increased activity of pro-apoptotic factor Bax and simultaneous reduction of anti-apoptotic factor Bcl-xL. The level of the expression of Bax and Bcl-xL depends on the stage of FSGS and indicates the step-dependent manner of glomerular and interstitial injuries development upon the chronic influence of albuminuria.

FR-PO524

eGFR, Renal, and Cardiovascular Risk and Nucleoside/Nucleotide Backbones of Human Immunodeficiency Virus Patients in the USA Jonathan A. Winston,[1] Grace Mccomsey.[2] *[1]Icahn School of Medicine at Mount Sinai; [2]Case School of Medicine.*

Background: HIV treatment involves choices in complex environments, and must balance disease management and potential safety issues (kidney and Cardiovascular diseases (CVD)) in an aging population. This study examined renal, CVD and comorbid conditions, and treatment of HIV patients.

Methods: Patients diagnosed with HIV using ICD-9 codes were selected from the Quintiles database (33M patients). Patients enrolled for ≥ 1 year during 2012-14, maintaining a single antiretroviral therapy, and for whom baseline eGFR could be computed were stratified based on backbone: regimens including tenofovir disoproxil fumarate (TDF), abacavir (ABC), or other (OTH). eGFR and rate of CV comorbidities at baseline were assessed.

Results: 14,942 HIV patients (mean age: 43; 76% male) were included; 85% TDF, 7% ABC, 7% OTH. Mean baseline eGFR was 99 mmol/l, with differences observed among regimens (102 TDF, 82 ABC, 87 OTH). Classified by degree of kidney impairment at baseline, regimen was highly correlated with level of impairment, with normal or mild impairment (eGFR≥60) more likely to be treated with TDF, and patients with moderate to

severe impairment (eGFR<60) more likely to be on ABC. Several CVD risk factors were more prevalent in ABC patients compared to TDF, hypertension (25% v 13%), dyslipidæmia (30% v 16%), and diabetes (12% v 5%) (p<0.001 in all) being the most common.

Conclusions: HIV patients often present with prevalent CVD risk and reduction in kidney function. Physicians make treatment choices that reflect concern for kidney function, consistent with labeling. This choice may come with cost, with more CVD risk factors correlated with alternative choices of NRTis. As some antiviral regimens may be associated with CVD while others with kidney disease, understanding CVD risk profile versus kidney function protection may help optimize care of patients.

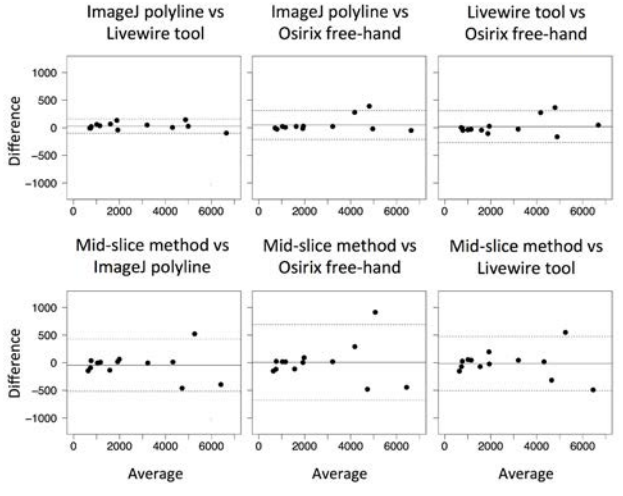
FR-PO525

Total Kidney Volume Computation in ADPKD: Different Methods in Comparison Kanishka Sharma,[1] Anna Caroli,[1] Katja Petzold,[4] Andreas L. Serra,[4] Giuseppe Remuzzi,[1,3] Andrea Remuzzi.[2] *[1]Bioengineering, Mario Negri Inst, Bergamo, Italy; [2]Biomedical Engineering, Univ of Bergamo, Bergamo, Italy; [3]Unit of Nephrology and Dialysis, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy; [4]Univ of Zurich, Zurich, Swaziland.*

Background: In ADPKD, kidney enlargement is associated with renal function decline, and total kidney volume (TKV) is gaining acceptance as surrogate marker of disease progression. In view of its effective use, TKV assessment should be as quick and accurate as possible. Aim of this study was to compare different TKV quantification methods.

Methods: TKV was computed on 13 MRIs from ADPKD patients enrolled in the EuroCYST Initiative (TKV=[707-6605] ml) by two tracers twice, using 4 methods: 1) polyline manual tracing with ImageJ software; 2) free-hand manual tracing with Osirix software; 3) semi-automatic tracing with customised ImageJ Livewire Plugin; 4) TKV estimation using mid-slice (Bae KT, Am J Nephrol 2013). Reproducibility, reliability, and agreement between methods were assessed.

Results: All of the methods were comparable in terms of intra- and inter-rater reliability (CCC=1, ρ>0.95). ImageJ polyline and Livewire tool showed highest agreement (30±65 ml difference), while mid-slice method showed largest discrepancies.



Mid-slice method required significantly less time than all other methods (~5 min), followed by Osirix free-hand (20±9 min), Livewire tool (24±9 min), and finally ImageJ polyline (35±12 min).

Conclusions: Mid-slice is much faster than whole kidney contouring for TKV quantification, but can provide only a clinical estimate of TKV. Whole kidney contouring must be used to monitor ADPKD progression and assess the efficacy of novel therapies. Livewire tool provides the best compromise between accuracy and time required.

Acknowledgments. This study was funded in part by the European Community (FP7-PEOPLE-MCA-ITN-317246, TranCYST project).

FR-PO526

Renal Reserve: Development of a Kidney Stress Test Kyle Rodenbach,[1] Dana F. Fuhrman,[2] Paula S. Maier,[1] Katherine D. Shaw,[1] George J. Schwartz.[1] *[1]Peds, Univ of Rochester, Rochester, NY; [2]Peds, Univ of Pittsburgh, Pittsburgh, PA.*

Background: Renal reserve (RR) is the difference in stimulated versus baseline glomerular filtration rate (GFR); it might predict future kidney health. The purpose of this study was to compare a meat versus liquid protein load in a cystatin-C-based (Cys-C) RR test using cimetidine-inhibited creatinine clearance (Cr Cl) and iohexol infusion clearance (Io Cl) for validation.

Methods: Participants (N=18) were screened for health status, blood pressure, and proteinuria. They followed a low protein diet and took cimetidine (20 mg/kg) for two days prior to the study. Water loading was used to maintain urine flow, and two hours were allotted for iohexol steady state equilibration. Participants 1-10 received a burger (1 g/kg protein); 11-15 received a ProCel® shake (1 g/kg protein); and 16-18 received a high dose ProCel® shake (1.5 g/kg protein). Data were analyzed for significance of RR. Cystatin-C estimated GFR (Cys-C eGFR) was calculated using the CKD-EPI Cys-C formula (Inker NEJM 2012) following IFCC calibration (ERM-DA471).

Results: Participants (N=18) had a mean (SD) age of 22 (2) years and were 39% male and 72% white. Baseline GFR (SD) in mL/min/1.73m^2 averaged 103.4 (14.7) for Cr Cl; 108.9 (9.0) for Io Cl (N=8); and 117.4 (6.1) for Cys-C eGFR. For the burger group (N=10), mean RR (SD) in mL/min/1.73m^2 was 17.1 (11.6) for Cr Cl (P=0.001); 8.4 (4.3) for Io Cl (P<0.001); and 4.7 (2.4) for Cys-C eGFR (P<0.001). For 1.0-1.5 g/kg shakes (N=8), mean RR (SD) in mL/min/1.73m^2 was 15.8 (5.8) for Cr Cl (P<0.001), 11.7 (9.0) for Io Cl (P=0.008), and 2.4 (2.9) for Cys-C eGFR (P=0.05). The burger and shake groups did not differ significantly in RR determined by Cr Cl, Io Cl, or Cys-C but Cys-C-based RR was significantly less than Io-based RR for both groups. There were no differences in post-load versus pre-load Cr/Io clearance ratios.

Conclusions: Cys-C-based RR following a burger provides a simple stress test of kidney function which was validated by classical renal clearances and can be applied to those who recover from acute kidney injury. Why Cys-C-based RR was smaller than Io RR, the reference standard, is a topic for future investigation.

FR-PO527

AT1 Receptor Antagonism Before Ischemia Prevents Acute Kidney Injury Transition to Chronic Kidney Disease Roxana Rodríguez Romo, Kenia Benitez, Rosalba Perez-villalva, Jonatan Barrera, Arturo Gómez, Gerardo Gamba, Norma O. Uribe-uribe, Norma Bobadilla. *Molecular Physiology Unit, Unidad de Fisiología Molecular, Inst de Investigaciones Biomédicas, UNAM e Inst Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico.*

Background: Despite the clinical recovery of an acute kidney injury (AKI) episode, progression to chronic kidney disease (CKD) could be observed on long time follow-up. The mechanisms are poorly understood. To analyzed if angiotensin II receptor blockade (ARB) before the ischemic insult is effective in abrogating the severity of the AKI episode and/or the progression to CKD.

Methods: Male Wistar rats were divided into 4-groups of rats: sham; sham plus losartan 3-d before surgery; bilateral renal ischemia for 45-min (UTxI); and losartan administration (3-d) before ischemia (Los-Pre). Animals were studied after 1, 3, 5, 15 days or 9-months. At the end of each experimental period, physiological, histopathological, inmunohistochemestry, biochemical and molecular studies were performed.

Results: UTxI group developed CKD characterized by renal dysfunction, proteinuria, renal hypertrophy, glomerulosclerosis, tubular atrophy and tubulointerstitial fibrosis. At the ultra-structural glomerular level, foot process effacement was observed, which was associated a reduction in immune-gold staining for nephrin. Renal injury was mediated by increased oxidative stress, inflammation and up-regulation of TGFβ, aSMA, and Colagen I protein levels. TGFβ overexpression was mainly observed in epithelial cells. Interestingly, in spite of, ARB did not prevent or reduced AKI severity; it was enough effective to prevent CKD. The renoprotection conferred by ARB was associated with the early recovery of renal blood flow, lesser inflammation and greater nuclear hypoxic inducible factor 1α (HIF1α) staining.

Conclusions: Our data shows that in spite of, losartan pre-treatment did not protect the rats against AKI, it was effective to prevent the transition to CKD. The mechanisms by which losartan prevented CKD were in part due to the early renal blood flow recovery, lesser inflammation and greater HIF1α nuclear translocation within the 15 days post-ischemia.

Specific Endothelial Heparin-Binding EGF-Like Growth Factor Deletion Ameliorates Renal Injury Induced by Chronic Angiotensin II Infusion
Fenghua Zeng, Lance A. Kloepfer, Raymond C. Harris. *Medicine, Vanderbilt Univ, Nashville, TN.*

Background: Transactivation of EGFR by angiotensin II (Ang II) plays important roles in the initiation and progression of chronic kidney diseases (CKD). In vitro studies suggested that HB-EGF may be a critical mediator in this process, whereas its role in vivo has not been reported.

Methods: Age-matched male littermates of HB-EGF$^{lox/lox}$ mice with endothelial-SCL-cre-ER (T) (+) or (-) were used. Tamoxifen injections produced control (HB$^{lox/lox}$) and mice with specific deletion of HB-EGF from endothelium (HB$^{endo-/-}$), which underwent uninephrectomy and osmotic minipump-mediated infusion with saline or Ang II for 8 weeks. Systolic blood pressures (SBP) were measured by tail-cuff. Renal injury was evaluated by albuminuria using urinary albumin/creatinine ratios and by morphology with periodic acid-Schiff (PAS) staining. Renal EGFR activation was determined by immunoblotting and immunostaining. Endothelium/podocyte injury, inflammation and renal fibrosis were evaluated by immunostaining.

Results: Compared to control, kidneys from HB$^{endo-/-}$ mice with Ang II-infusion had significantly reduced EGFR activation. Endothelial HB-EGF deletion did not significantly prevent the hypertension induced by Ang II infusion, albeit lower SBP was detected in HB$^{endo-/-}$ mice compared to HB$^{lox/lox}$ mice. However, it decreased Ang II-infusion related renal injury, as demonstrated by 1) less albuminuria; 2) less glomerulosclerosis with glomerular score of 0.793 versus 1.652 in the control; 3) preserved endothelial integrity and decreased podocyte injury, as shown by more glomerular tufts area and WT1 positive cells, and less apoptotic cells measured by cleaved caspase 3 and TUNEL staining; 4) reduced inflammation in perivascular area and interstitium measured by F4/80 and CD3 immunostaining; and 5), reduced renal fibrosis, as shown by α-SMA immunostaining.

Conclusions: Shedding of HB-EGF from endothelium plays an important role in Ang II induced renal injury by linking Ang II-AT1R with EGFR transactivation. Inhibition of HB-EGF shedding could be a potential therapeutic strategy for CKD.

Effects of Acute Kidney Injury (AKI) Severity and Co-Morbidities on Chronic Kidney Disease (CKD) Progression
Gregory John Wilson,[1,2] Adrian Lawrence Kark,[1,2] Andrew John Mallett,[1,2,3,4] Anne Salisbury,[1,2,4] Zaimin Wang,[2,4] Helen G. Healy,[1,2,4] Wendy E. Hoy.[2,4] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Australia; [2]CKD.QLD and NHMRC CKD.CRE, The Univ of Queensland, Australia; [3]Inst for Molecular Bioscience and School of Medicine, UQ, Australia; [4]Centre for Chronic Disease, UQ, Australia.*

Background: AKI is a common and important cause of CKD. It remains unknown how AKI severity influences CKD progression. Which co-morbidities influence the progression of CKD also remains undetermined.

Methods: We aimed to explore whether AKI severity and patient comorbidities influence CKD progression. Patients with CKD associated with a clinical diagnosis of AKI were identified in the Royal Brisbane & Women's Hospital cohort (n=1150) of the CKD.QLD registry. AKI events were confirmed through historical creatinine values (2005 onward), and severity determined using AKIN criteria. CKD progression was assessed by change in glomerular filtration rate per year (DeGFR/yr) based on initial and final eGFR(CKD-EPI) values. All co-morbidities identified at the time of enrolment into the registry were explored.

Results: 384 patients were recorded as having a primary or secondary AKI diagnosis; 157 of these (99 male, mean age 67yrs) were biochemically confirmed. 133 patients (84.7%) were identified as Stage 1 AKI, 16 (10.2%) as Stage 2 and 8 (5.1%) as Stage 3. A one-way ANOVA revealed that AKI severity did not modulate CKD progression. However, numerically DeGFR/yr was largest for Stage 3 patients (5.1mL/min/1.72m^2), and smallest for Stage 1 patients (1.6mL/min/1.72m^2). The only two co-morbidities found to influence CKD progression were diabetes mellitus (DM; 35.6% of patients) and peripheral vascular disease (PVD; 12.1% of patients). CKD progression was significantly increased in patients with DM compared with patients without (DeGFR/yr 3.7mL/min/1.72m^2, $p<0.001$), and patients with PVD compared with those without (DeGFR/yr 4.4mL/min/1.72m^2, $p<0.05$).

Conclusions: Surprisingly, AKI severity did not alter CKD progression. Both DM and PVD influenced CKD progression in patients with AKI suggesting an increased vulnerability to AKI in these patients.

FR-PO530

Association Between Gut Microbiome and Cardiovascular Risk in Chronic Kidney Disease Patients with Type 2 Diabetes Mellitus
Ruchi Singh, Tetyana L. Vasylyeva. *Pediatrics, Texas Tech Health Sciences Center, Amarillo, TX.*

Background: Diabetes is one of the leading causes of CKD. It is well established that patients with T2DM often experience persistent low-grade inflammation leading to microvascular deterioration and progression of vascular complications along with impaired gut motility, which impacts their microbiomes. The aim of the study is the assessment of gut microbiota, plasma zonulin, and inflammatory cytokines (TNF-α, IL-6) in conjunction with FGF-23, ET and levels of LPS in CKD (stage 4 and 5) patients with Diabetic Nephropathy (DN).

Methods: Healthy controls were matched by age and gender. Their dietary habits have been reviewed. Total of 40 subjects participated in the study. TNF-α, IL-6, FGF 23, LPS. ET-1 and zonulin, levels were measured by ELISA and quantitative analysis of gut microbiota composition (454 pyro sequencing).

Results: Higher circulation serum zonulin, TNF-α, and IL-6, FGF 23 LPS, ET-1 levels were found in the CKD (stage 4 and 5) with T2DM. Gut microbiota in T2DM patients with advanced CKD was substantially different from healthy population with increased in percentage of LPS producing bacteria. Significant diversity was observed in gut microbiota in study subjects compared to control group. CKD patients had high serum concentration of zonulin, a marker of leaky gut syndrome. Zonulin concentration was found positively correlated with LPS, inflammatory markers and FGF-23.

Conclusions: Gut microbiota is a modifiable factor and zonulin could be a potential future target to control chronic inflammatory responses. Gut microbiota and increased gut permeability in patients with advanced CKD secondary to DN results in high level of circulation LPS that mediates chronic inflammation which was implicated in deterioration of cardiovascular health.

Metabolomics of Chronic Kidney Disease in Cohort of Patients Given Probiotics
Subodh J. Saggi,[1] Eli A. Friedman,[1] Natarajan Ranganathan,[3] Kelly Mercier,[2] Susan Mcritchie,[2] Susan Sumner.[2] *[1]Nephrology/Medicine, SUNY Downstate Medical Center, New York, NY; [2]Metabolomics, Research Triangle Inst, Research Triangle Park, NC; [3]Kibow Biotechnology Inc., Kibow Biotechnology Inc., Newtown Square, PA.*

Background: Persistent reduction in Glomerular Filtration Rate (GFR) below 60 ml/min/1.73 m^2 BSA over 3 months are hall marks of Chronic Kidney Disease (CKD). Urea is still considered a major uremic toxin clinically despite the description of middle molecules as being toxic. Persistent elevation of BUN may accompany reductions in GFR in some patients. We were specifically interested in obtaining pilot data identifying metabolites that differentiated patients with CKD whose BUN decreased after 4 months of probiotics treatment and its possible mechanisms.

Methods: Broad spectrum ^{1}H-NMR metabolomics was used to analyze baseline and 6 month plasma samples frozen from a phenotypically characterized cohort of patients with CKD Stage 3 and below from a prior Probiotic Renadyl™ study. NMR spectral data of baseline and 6 month plasma samples were analyzed after identical treatment of all samples. A total of 24 baseline samples were differentiated by a change in their BUN. Principal components analysis and orthogonal partial least squares discriminant analysis was used to analyze the data and determine the metabolites that best differentiated the phenotypic groups.

Results: Characteristics of the cohort population were age 57.7 ± 14 yrs, mean BMI 31.3 ± 6.1 Kg/m^2, 10 males and 14 females, 20 with HTN, 8 with DM, 11 Caucasian and 9 AA, 3 other, 1 unknown. 16 patients who had a decrease in BUN after 4 months of probiotics treatment could be differentiated based on baseline samples from those whose BUN increased or did not change.The majority of the metabolites that differentiated the groups were microbiome related metabolites.

Conclusions: Metabolomics analysis revealed a signature of metabolites that were associated with a decrease in BUN, and holds promise for use in predicting individuals with CKD that would most benefit from use of probiotics. The majority of the metabolites important to the differentiation of groups map to pathways involved in microbial metabolism.

Potential Uremic Toxin Precursors in the Gut Identified by Metabonomics and Proteomics
Liwen Zhang,[1] Hongli Jiang.[2] *[1]School of Medicine, Xi'an Jiaotong Univ, Xi'an, Shaanxi, China; [2]Hemodialysis Center, First Affiliated Hospital of Medicine School, Xi'an Jiaotong Univ, Xi'an, Shaanxi, China.*

Background: Many factors, e.g., the intestinal bacterial disorder, result in the species and amounts of harmful substances in the gut increasing, which leads to the increase of uremic retention molecules (URMs) in blood. These URMs may be classified according to their site of origin, that is, endogenous metabolism, microbial metabolism, or exogenous intake. The latter two are known as gut-derived uremic toxins, i.e., gut is a significant origin of URMs; but, it is currently unclear of the profile of these uremic toxins.

Methods: Excluding special factors which affected the intestinal environment, the subjects were divided into two groups: hemodialysis patients with end-stage renal disease (HD group, n = 20) and healthy controls (CT group, n = 20). Fecal metabonomics based on the ultra-performance liquid chromatography-tandem mass spectrometry was undertaken to explore the low molecular weight metabolites, and fecal proteomics based on the two-dimensional gel electrophoresis was employed to investigate the high molecular weight proteins. The data was analyzed with statistic and bioinformatic methods.

Results: Thirty-three metabolites and 31 proteins were identified. Among them, 17 metabolites and 13 proteins were significant higher in HD group than those in CT group, including phenols, which are well-known uremic toxins originating from the gut; reactive carbonyl compounds (RCC), which are well-known URMs in serum but first identified in the gut; other harmful metabolites (e.g., fenthion, halosulfuron-methyl and diethylpropion), and two inflammation-associated proteins. However, the levels of 16 metabolites and 18 proteins were lower in HD group comparing to CT group, including ajoene, which has been shown to exhibit anti-microbial and anti-cancer functions, and three proteins, which have indicated anti-inflammatory and anti-cancer activities.

Conclusions: This study not only demonstrated RCC URMs originated from the gut, but also identified numerous potential uremic toxin precursors and deficient beneficial substances in the gut of uremic patients.

AST-120 Affects the Level of Circulating TNF-Alpha Receptors That Predict Both Renal and Cardiovascular Outcomes in Patients with Advanced Renal Dysfunction

Ran-hui Cha,[1] Dong Ki Kim,[2] Yon Su Kim.[2] *[1]Internal Medicine, National Medical Center, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea.*

Background: Tumor necrosis factor alpha and its two receptors have a critical role in kidney diseases. We aimed to establish the role of circulating TNF-alpha receptors (cTNFRs) as a new biomarker of renal disease and to identify the impact of AST-120 on the level.

Methods: 579 patients from 11 medical centers in Korea were prospectively recruited and followed up for 36 months after randomization into AST-120 and control arms. A total of 6 gram of AST-120 was given to participants in AST-120 arm as well as conventional treatment. cTNFRs were measured by ELISA method at the time of randomization and 1 year after. The renal outcome was composite of serum creatinine (SCr) doubling, 50% reduction of estimated glomerular filtration rate (eGFR), or initiation of renal replacement therapy.Major adverse cardiovascular events (MACE) were also evaluated.

Results: A total of 465 patients were analyzed. Mean SCr and eGFR level was 2.8 ± 0.67 mg/dl and 26.79 ± 7.263 ml/min/1.73m^2, respectively. The levels of cTNFRs throughout the study period were not different between two treatment arms. But the higher AST-120 compliance patients had, the lower cTNFRs they showed in the AST-120 arm. The highest tertile of cTNFRs showed the highest cumulative rate of composite renal outcomes followed by the intermediate tertile of cTNFRs after the adjustment for traditional risk factors. More change of cTNFRs was also independently associated to the more occurrence of composite renal outcomes. MACEs occurred more frequently in patients with higher baseline cTNFRs and more change of cTNFRs (log-rank P = 0.01, 0.002 and 0.021 for cTNFR1, cTNFR2, and change of cTNFR2, respectively) and the significance of cTNFR2 remained after adjustment for diabetes, CKD stage, and proteinuria.

Conclusions: Baseline and change of cTNFRs did not improve the predictability of composite renal outcomes in comparison with classic biomarkers. But cTNFRs predicted both renal and cardiovascular outcomes in patients with advanced renal dysfunction. And AST-120 was effective to lessen the increase of cTNFRs.

FR-PO534

Swimming Exercise Training (EXE) Normalize Blood Urea Nitrogen (BUN), Decrease Glomerulosclerosis, and Attenuates the Loss of Myokine IL6 in Rats with Chronic Kidney Disease (CKD) by 5/6 Nephrectomy (5/6Nx)

Rafael Luiz, Rodolfo Rosseto Rampaso, Kleiton Augusto Santos Silva, Luciana Jorge, Edson Andrade Pessoa, Maria A. Gloria, Mario Luis Ribeiro Cesaretti, Nestor Schor. *Nephrology, Federal Univ of São Paulo, São Paulo, Brazil.*

Background: The aim of this study was to evaluate the EXE effects on renal function, glomerulosclerosis and myokine IL6 (has been associated with stimulation of hypertrophic muscle growth and myogenesis through regulation of the proliferative capacity of muscle stem cells) in rats with 5/6Nx.

Methods: Adult Wistar rats were divided in groups (n=8): Control (CS), Control+EXE (CE), Sedentary 5/6Nx (NS) and 5/6Nx+EXE (NE). The protocol was employed in 5/6Nx rats after 7 days from the surgical procedures. EXE periods were 60min/day/5 days a week during 8 weeks. It was evaluated arterial pressure (AP), maximal exercise test (MEtest), creatinine clearance (CrCl), BUN, proteinuria (uProt), glomerulosclerosis, myokine IL6 (by Luminex) as well mortality rate.

Results: EXE did not modify the increment in MAP but prevent, at least in part, a lower decline in the MEtest caused by 5/6Nx (29±1 vs 16±2 m/min, $p<0.05$). A higher CrCl in NE was observed compared with NS, 2.27±0.33 vs 0.96±0.20 ml/min, respectively ($p<0.05$). BUN was normalized in NE (43.62±7.30 mg/dL). Proteinuria was not significantly different in NE vs NS group (36.87±3.53 vs 40.13±2.35 mg/24h). Glomerulosclerosis was 48% higher in NS vs NE. Myokine IL6 (pg/ml) was decreased in NS (286.40±14) and attenuated the loss in NE (384.00±20.82). A higher mortality rate was observed in NS (70%) vs NE group (39%, $p<0.05$).

Conclusions: Results suggested that the EXE minimize the impact of 5/6Nx, by decreasing glomerulosclerosis and reducing the impact on CrCl (42%). Finally, attenuating myokine IL6 in NE, the decreasing mortality rate in NE vs NS and by minimizing the impact of 5/6Nx on CrCl indicate that EXE in this protocol, induced protection on renal function. Thus, it is reasonable to suggest that EXE could be an additional strategy to be employed in CKD.

Does Autophagosome-Proteolysis Contribute to CKD-Induced Muscle Atrophy?

Zhen Su,[1] Haidong Wang,[3] Janet D. Klein,[3] William E. Mitch,[2] Xiaonan H. Wang.[3] *[1]Dept of Nephrology, The First Affiliated Hospital of Wenzhou Medical Univ, Wenzhou, Zhejiang, China; [2]Nephrology, Baylor College of Medicine, Houston, TX; [3]Renal Medicine, Emory Univ, Atlana, GA.*

Background: CKD-induced muscle wasting results from activation of the ubiquitin proteasome system (UPS). Since FoxO simulates the UPS but also activates autophagosomes, we hypothesized that autophagosome-induced proteolysis may contribute to CKD-induced muscle wasting.

Methods: CKD model in mice: subtotal nephrectomy for one month. Muscle overloading model: removal of gastrocnemius and soleus to overload the plantaris muscle (mimics resistant exercise) in normal and CKD mice. Acupuncture with low frequency electric stimulation (Acu/LFES) was applied 15 minutes daily for 2 weeks (Hu, JASN, 26:626 2015). Electrical stimulation used a consistent pulse, electric frequency 20HZ, current 1mA.

Results: Both exercise and Acu/LFES reduced CKD muscle loss. In muscles of CKD mice, mRNAs related to autophagy-lysosomal function, Bnip3, Atg12, Atg8, LC3II and Beclin-1, were upregulated and Bnip3, Beclin-1 and LC3II proteins were increased. Acu/LFES treatment reversed these changes. Exercise in control mice also increased autophagy-lysosomal related protein LC3-II, Beclin-1, P62 and Vps34. The levels of these mediators were not additive to changes observed in mice with CKD. We cultured C2C12 myotubes in uremic serum and found increased autophagy markers, indicating activation of autophagosomes. Acidification alone did not stimulate autophagy markers. Based on the C2C12 results, the UPS, but not autophagosomes, is responsible for degradation of structural proteins (myosin and actin).

Conclusions: 1) autophagosome-mediated proteolysis occurs in CKD-induced muscle atrophy. In mice with CKD, the UPS was principally involved in muscle proteolysis; the role of autophagosomes was convoluted. 2) Prevention of muscle atrophy by exercise is not due to inhibition of the autophagy-lysosomal proteolysis pathway in CKD. 3) Muscle atrophy cannot be equated with increased autophagy markers. 4) Acu/LFES and exercise promote different autophagy consequences.

Indoxyl Sulfate, a Uremic Toxin, Accelerates Skeletal Muscle Atrophy in CKD Condition

Yuki Enoki,[1] Hiroshi Watanabe,[1] Masafumi Fukagawa,[2] Toru Maruyama.[1] *[1]Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto-shi, Japan; [2]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara-shi, Japan.*

Background: Skeletal muscle atrophy is often observed in chronic kidney disease (CKD) patients, especially in patients underlying hemodialysis. Uremic toxins have been known to link to CKD complications. However there has been no report on the relationship between uremic toxins and skeletal muscle atrophy. The purpose of this study is to investigate the involvement of uremic toxins on skeletal muscle atrophy observed in CKD condition.

Methods: *In vitro* cytotoxicity of uremic toxins on cell proliferation and differentiation was evaluated by using a mouse myoblast cell line (C2C12). The effect of uremic toxin on proteolysis and protein synthesis system in C2C12 was also evaluated. In the animal study, we examined the contribution of uremic toxin on muscle atrophy using uremic toxin overloaded half- or 5/6-nephrectomized mice.

Results: We focused on six protein bound solutes including indoxyl sulfate (IS), indole acetic acid, *p*-cresyl sulfate, hippuric acid, kynurenic acid and 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid. Among these uremic toxins, IS significantly inhibited proliferation and differentiation of C2C12 myoblast cell, and decreased phosphorylation of Akt. Moreover, IS significantly increased atrophy-related genes expression but it did not affect differentiation-related genes expression. In the animal experiments, IS-overload reduced body weights and skeletal muscle weights of half- or 5/6-nephrectomized mice, and consequently weakened its muscular endurance. IS-overload mice showed increased skeletal muscle atrophy-related genes expression. In the same experimental condition, IS also induced the expression of inflammatory cytokine and transforming growth factor-β in skeletal muscle cells.

Conclusions: IS is the potent uremic toxin inducing skeletal muscle atrophy associated with CKD by increasing muscle atrophy-related genes.

FR-PO537

Myostatin Stimulates Progenitor Cells to Differentiate into Fibrocytes Leading to Muscle Fibrosis in Chronic Kidney Disease

Liping Zhang,[1] Jiangling Dong,[1,2] William E. Mitch.[1] *[1]Medicine/Nephrology, Baylor College of Medicine, Housron, TX; [2]Life Science& Engineering College, Northwest Univ for Nationalities, Lanzhou, Gansu, China.*

Background: In chronic kidney disease (CKD), fibrosis develops in damaged kidneys leading to loss of functions. Fibrosis in muscle also complicates CKD but the identity of cells developing into fibrocytes and mechanisms causing fibrosis are not defined. The potential precursors of muscle fibrosis are mesenchymal progenitor cells (fibrotic and adipogenic progenitors (FAPs)) while mechanisms causing fibrosis include myostatin as

CKD raises its expression and muscle injury can stimulate injured muscles to develop fibrocytes. Our hypothesis is that CKD stimulates myostatin expression causing FAPs to differentiate into fibrocytes.

Methods: 1). we isolated and cultured FAPs, adding recombinant myostatin to determine if it causes FAPs to proliferate and differentiate into fibrocytes. 2) We isolated GFP-labelled FAPs from transgenic, GFP-expressing mice and transplanted them into tibialis anterior (TA) muscles of CKD mice. We assessed conversion of FAPs into GFP-fibrocytes using α-SMA expression. 3) CKD mice were injected with an anti-myostatin peptibody to determine if myostatin stimulates muscle fibrosis. 4) Interactions between myostatin signaling and FAP conversion to fibrocytes were tested by knocking down Smad3 with a lentivirus expressing Smad3 SiRNA.

Results: In cultured FAPs, myostatin stimulated their proliferation and conversion into fibrocytes and there is proliferation of FAPs in injured muscles of CKD mice. GFP-labelled FAPs transplanted into TA muscles of CKD mice differentiate into fibrocytes identified as expressing the fibrosis marker, α-SMA. FAP proliferation and muscle fibrosis were prevented in CKD mice injected with the anti-myostatin peptibody. Finally, Smad3 knock-down blocked FAP differentiation into fibrocytes indicating that a myostatin to Smad3 pathway is responsible for the conversion of FAPs to fibrocytes.

Conclusions: CKD stimulates myostatin production to activate FAPs which differentiate into fibrocytes. The process is blocked by an anti-myostatin peptibody, providing a new target for preventing muscle fibrosis as a complication of CKD.

FR-PO538

Effect of Methoxy Polyethylene Glycol – Epoetin Beta on Plasma Levels of IL-1β, TNF-RI, TNF-RII, sFAS, sFASL, TGFβ, MMP-9 in Patients with CKD Piotr Bartnicki,[1] Ewa Majewska,[2] Zbigniew Baj,[2] Jacek Rysz.[1] *[1]Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Poland; [2]Dept of Pathophysiology and Immunology, Medical Univ of Lodz, Poland.*

Background: In patients with CKD are observed disturbances of immune cells function and endothelium dysfunction with high tissues fibrosis. ESAs using in these patients, beyond anemia correction seem to have renoprotective effect and slow progression of CKD. In this study we aimed to determine effect of methoxy polyethylene glycol – epoetin beta (Mircera) on plasma levels of selected parameters in predialysis patients with CKD.

Methods: 28 patients with CKD and anemia, treated with Mircera, were enrolled to the study. The healthy control group included 15 volunteers. Plasma levels of evaluated parameters were measured with available enzyme – linked immune-sorbent assay (ELISA) kits.

Results: The results of our study are shown in the table.

	CKD before treatment	CKD after treatment	Control group
Hb [g/dl]	9.6 (9.1 – 10.1) *	11.6 (11.1 – 12.1) *•	14.4 (13.3 – 14.9)
eGFR [ml/min]	16.4 (13.9 – 21.8) *	16.6 (14 .0 – 23.3) *	65 (63 – 74)
IL-1β [pg/ml]	2.72 (1.63 – 3.81) *	2.97 (2.24 – 3.7) *	1.29 (1.25 – 1.33)
TNF-RI [pg/ml]	5268 (3741 - 6795) *	5430 (3906 - 6954) *	1136 (912 -1360)
TNF-RII [pg/ml]	8092 (7183 - 9001) *	9308 (7912 - 10703) *•	2360 (1899 - 2821)
sFAS [pg/ml]	3325 (2444 - 4207) *	3174 (2666 - 3682) *	507 (333 - 580)
sFASL [pg/ml]	90.3 (61 – 119.6) *	87.5 (66.1 – 108.9) *	60.1 (20.4 – 100.8)
TGFβ [pg/ml]	25.2 (16.3 – 34.1) *	25.3 (12.1 – 38.5) *	12.3 (8.7 – 15.9)
MMP-9 [ng/ml]	1125 (659 – 1591) *	687 (330 – 1044) *•	273 (157 – 389)

*p < 0.05 to control group, •p < 0.05 to CKD before treatment

Conclusions: Plasma concentrations of evaluated parameters are significantly higher in CKD patients in comparison to control group. After ESA treatment plasma level of TNFII was significantly higher and MMP-9 was significantly lower in CKD patients. These data suggest that Mircera used in correction of anemia in CKD might influence on immune cells function, apoptosis and tissue fibrosis.

FR-PO539

Qualitative Changes in Erythrocytes in Chronic Kidney Disease Ken Aizawa, Ryohei Kawasaki, Yoshihito Tashiro, Michinori Hirata, Koichi Endo, Ken-ichi Serizawa, Yasushi Shimonaka. *Product Research Dept, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan.*

Background: Therapeutic control of anemia in chronic kidney disease (CKD) is assessed by monitoring hemoglobin (Hb) levels. However, monitoring Hb alone could potentially fail to reveal pathological changes in erythrocytes, because erythrocyte lifespans are shorter in CKD. Shortening of erythrocyte lifespans may attenuate erythropoietin responsiveness, resulting in poor prognosis of CKD. Erythrocyte lifespans are thought to be shortened by qualitative changes such as deterioration of deformability and stability, but it is not yet clear whether these aspects are changed in CKD.

Methods: To assess qualitative changes in erythrocytes were first confirmed in a rat model of iron-deficiency anemia. Deformability was quantified by laser diffraction ektacytometry and stability was quantified by hemolysis test. We next produced CKD model rats by anti-Thy1.1 antibody injection plus uninephrectomy. Epoetin beta pegol (C.E.R.A., 25 mg/kg) was intravenously injected the day after surgery. At 11 wks, Hb levels, erythrocyte deformability and stability, plasma urea nitrogen (UN) and creatinine (pCre) were assessed.

Results: Iron-deficiency rats showed significant anemia and had impaired erythrocyte deformability and stability. These changes in erythrocytes were almost normalized by administration of iron sucrose. In the CKD model, Hb level was significantly decreased and deformability and stability of erythrocytes were significantly impaired. Stability significantly recovered and deformability tended to recover in the C.E.R.A. group, although there was no significant difference in Hb levels between the disease group and C.E.R.A. group. Kidney function (UN and pCre) correlated significantly with stability, but not with deformability. Morphologic parameters (mean corpuscular volume and red cell distribution width - standard deviation) did not reflect changes in deformability and stability.

Conclusions: Deformability and stability of erythrocytes were impaired in CKD rats, and may be linked with kidney dysfunction. Focusing on qualitative aspects of erythrocytes may provide a better understanding of pathological conditions and therapeutic benefit in anemia.

FR-PO540

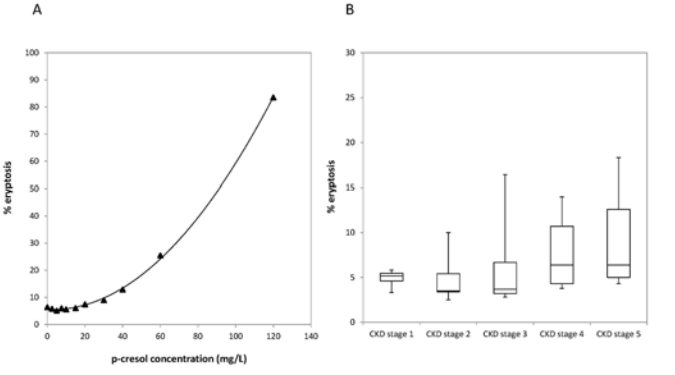
Eryptosis in Chronic Kidney Disease Grazia Maria Virzì, Anna Clementi, Alessandra Brocca, Massimo de Cal, Claudio Ronco. *Nephrology-IRRIV.*

Background: Even though anemia in CKD results mainly from the lack of erythropoietin, accelerated erythrocyte death(eryptosis) seems to be a contributor factor. Eryptosis is characterized by cell shrinkage and cell membrane scrambling with phosphatidylserine(PS)-exposure at the erythrocyte (RBC) surface. Eryptosis may be triggered by some uremic toxins. P-cresol is an uremic toxin which has negative cardiovascular and cytopathic effects. This study explored if eryptosis is triggered by p-cresol and if different stages of CKD may influence erythrocyte death.

Methods: RBCs from healthy subjects were incubated in vitro at a hematocrit of 0.4% in RPMI with different concentrations of p-cresol (0-2.5-5-10-20-40mg/l) and with plasma from CKD patients (5 for each stage) for 24hours. PS exposure was estimated from AnnexinV binding in flow cytometer.

Results: Increasing concentrations of p-cresol modified significantly the percentage of PS exposure on RBC surface, thus suggesting that increasing concentrations of p-cresol may stimulate eryptosis in vitro. Moreover, there was no significant difference in terms of median values of eryptosis between CKD stages, but a positive trend was evident: eryptosis increase with CKD progression.

	CKD1	CKD2	CKD3	CKD4	CKD5
ERYPTOSIS %	4.7 (4.2-5.0)	3.5 (3.4-5.4)	3.7 (3.2-6.7)	6.4 (4.3-10.3)	6.4 (5.0-12.6)



Conclusions: In addition to its known cardiovascular and cellular effects, p-cresol seems to stimulate eryptosis in vitro and increasing concentrations of this uremic toxin may be responsible for higher levels of eryptosis in vivo. Our data show that CKD plasma contains components able to trigger eryptosis and different stages of CKD may be responsible for different levels of RBC death, thus suggesting that progression of CKD may increase eryptosis in vivo. These results suggest a role of uremic toxicity in the genesis of eryptosis and renal anemia. It is necessary to increase the sample size to validate our hypothesis.

FR-PO541

Palmitate Exacerbates Renal Anemia: Suppression of Renal Erythropoietin Production via Endoplasmic Reticulum Stress Reiko Inagi,[1] Thitinun Anusornvongchai,[1] Yu Ishimoto,[2] Akira Okada,[2] Norio Suzuki,[3] Masayuki Yamamoto,[3] Masaomi Nangaku.[2] *[1]Div of CKD Pathophysiology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Divs of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; [3]Tohoku Univ School of Medicine, Sendai, Japan.*

Background: Derangement of erythropoietin (EPO) production in renal EPO-producing (REP) cells causes renal anemia. Palmitate induces endoplasmic reticulum (ER) stress that contributes to glomerular and tubular cell damages. Thus, we evaluated the effect of palmitate-ER stress axis on EPO production in REP cells.

Methods: C57/BL6 or the mice, in which the renal EPO gene was replaced with GFP or REP cells were lineage labeled with tdTomato, were daily injected with palmitate

(BSA-conjugated, PAL) or BSA for 11 days or fed with high palmitate (10%) diet for 4 months. The hypoxia-induced EPO production or ER stress status in kidney, especially in REP cells, were then assessed by real-time PCR, WB, and IF assay. In *in vitro* study, we used HepG2 (hepatic EPO producing cells) treated with PAL.

Results: PAL (injection and diet) suppressed EPO production *in vivo* and *in vitro* under hypoxia (HIF activation with $CoCl_2$). It was associated with activation of ER stress signal (ATF4 and XBP-1, $p<0.05$). ATF4 activated by PAL significantly bound to a novel ATF4 binding site (TGACCTCT) at the 3'-enhancer region of EPO gene and suppressed the enhancer activity and subsequent EPO mRNA expression. HepG2 overexpressing dominant negative ATF4 ameliorated the suppression of EPO production by PAL. Importantly, PAL did not change the REP cell number, while REP cells markedly declined EPO production by PAL. In contrast, the number of REP cells positive for ATF4 was increased by PAL, indicating that suppression of EPO production in REP cells by PAL was mediated by ATF4 activation, namely ER stress.

Conclusions: EPO production by REP cells was suppressed by palmitate, especially under hypoxic condition, via the ER stress pathway (ATF4 activation). The link between dyslipidemia (palmitate) and ER stress may contribute to development and progression of renal anemia, and subsequent CKD and highlight the impact of palmitate diet on CKD prevention.

FR-PO542

The Function of Integrinβ4 in Epithelial-to-Mesenchymal Transition of HK2 Cells Qi Wang, Yan Wang, Xiaoyan Huang, Zibo Xiong, Zuying Xiong. *Dept of Nephrology, Peking Univ Shenzhen Hospital, Shenzhen, Guangdong, China.*

Background: To explore the function of integrinβ4 in epithelial-to-mesenchymal transition (EMT)of HK2 cells, and further study the role of integrinβ4 in renal fibrosis.

Methods: (1) Cultered HK2 cells were divided into 4 groups: 0ng/ml TGFb1 treated group (negative control), 1ng/ml TGFb1 group , 3ng/ml TGFb1 group and 9ng/ml TGFb1 group .(2) We constructed a stable shRNA mediated repression of integrinβ4 in HK2 cells and divided into 4 groups: control-shRNA HK2 cells without TGFb1; control-shRNA HK2 cells with 5ng/ml TGFb1; β4-shRNA HK2 cells without TGFb1; β4-shRNA HK2 cells with 5ng/ml TGFb1 (3) The vivo experiment was performed in IgA nephropathy kidney tissues obtained from 45 patients that underwent a biopsy procedure during 2013-2014. According to the degree of tubulointerstitial lesion, kidney specimens were divided into 3 groups: mild lesion, moderate lesion, and severe lesion. We handle normal kidney portions as controls. The expressions of integrinβ4, E-cad, CTGF and α-SMA were assessed by qRT-PCR and westernblot; immunofluorescence was used in different degrees of tubulointerstitial lesions.

Results: (1) Compared with negative control, integrinβ4 and E-cad were significantly lower, however, CTGF and α-SMA were increased (2) Integrinβ4 and E-cad in β4-shRNA HK2 cells group were lower than control-shRNA HK2 cells, in contrast, CTGF and α-SMA were increased; integrinβ4 and E-cad with TGFb1 treatment were significantly lower than without TGFb1 groups, CTGF and α-SMA expressions were increased. (3) Compared with mild lesion group, E-cad staining in moderate lesion group and severe lesion group reduced, α-SMA staining and integrinβ4 staining increased. After being further analyzed, the most of integrinβ4 staining located in neonatal renal tubules.

Conclusions: Integrinβ4 was decreased in the process of EMT, and reduced integrinβ4 can exacerbate HK2 cells from epithelial cells transition to mesenchymal cells, therefore loss of integrinβ4 may be the marker of TIF. However, the results of vivo experiment appeared to contradict vitro experiments, the reason of this phenomenon may be that many neonatal renal tubules possess the ability of proliferation.

Signal Regulatory Protein-α Is Elevated in Uremic Cardiomyopathy and May Exacerbate Muscle Fibrosis Sandhya S. Thomas, Jiangling Dong, Liping Zhang, William E. Mitch. *Medicine, Baylor College of Medicine, Houston, TX.*

Background: Insulin resistance in chronic kidney disease (CKD) begins early in the disease, compromising anabolic responses to insulin/IGF-1 signaling. We have previously demonstrated that a novel protein, signal regulatory protein alpha (SIRPα) is involved in insulin signaling, exacerbating skeletal muscle metabolism. We now describe for the first time elevation of SIRPα in CKD cardiac muscle which not only adversely influences insulin signaling, but may exacerbate muscle fibrosis.

Methods: CKD was created via subtotal nephrectomy and mice with CKD greater than 2 months hearts were harvested and left ventricle muscle samples were examined for SIRPα, IRS-1, α-SMA, GAPDH. Additionally, C2C12 myoblasts were treated to overexpress SIRPa vs. GFP plasmid. Also, myoblasts were transfected with silencing RNA (SiRNA) SIRP-α or scrambled SiRNA (control). Western blots analysis was performed based on skeletal and cardiac muscle cell lysates.

Results: After ~2 months of CKD, the mice experience left ventricle hypertrophy with a heart weight to body weight that is significantly larger vs. control mice. SIRPa was significantly increased in cardiac muscles of mice with CKD, with reduction in tyrosine phosphorylation of IRS-1. This finding was previously reported in skeletal muscles of mice with CKD. Additionally, fibrosis marker α-SMA was increased in cardiac muscles of mice with CKD vs. control mice. In order to determine a cause and effect relationship, SIRPa was overexpressed utilizing a SIRPa plasmid vs. GFP plasmid for control. In myoblasts in which SIRPa was overexpressed, fibrosis marker α-SMA increased. Finally, when we silenced SIRPα in muscle cells treated with a cytokine mixture, containing cytokines present in CKD patients, fibrosis marker α-SMA was downregulated.

Conclusions: These results imply that SIRPα increases fibrosis, and suggesting that SIRPα may have influences on cardiac muscle fibrosis via a new pathway in chronic kidney disease. Ultimately blocking SIRPα in heart muscle may improve cardiac fibrosis associated with chronic kidney disease.

Retinal Microvascular Abnormalities and Incidence and Progression of Chronic Kidney Disease Charumathi Sabanayagam,[1,2] Peng Guan Ong,[1] Boon Wee Teo,[3] Carol Y. Cheung,[1,2] Ching-Yu Cheng,[1,2] Ecosse L. Lamoureux,[1,2] Tien yin Wong.[1,2] *[1]Singapore Eye Research Inst, Singapore; [2]Office of Clinical Sciences, Duke-NUS Graduate Medical School, Singapore; [3]National Univ of Singapore, Singapore.*

Background: To examine the longitudinal association of a panel of retinal vascular parameters, markers of microvascular damage, with the incidence and progression of chronic kidney disease (CKD) in middle-aged Asian adults.

Methods: The population consisted of a cohort of Malay adults aged 40-80 years examined from 2004-06 and again from 2010-2012 (n=1464; 1306 free of CKD and 158 with pre-existing CKD). The outcomes were incidence (estimated glomerular filtration rate [eGFR]<60 mL/min/1.73m^2+25% decrease in eGFR) and progression of CKD (drop in eGFR category [≥60, 30-59, 15-30, <15]+25% decrease in eGFR or an annualized eGFR rate>3 mL/min/1.73m^2/year). Retinal vascular parameters (arteriolar and venular caliber, tortuosity, branching angle, and fractal dimension were measured from baseline retinal photographs using a computer-assisted program (Singapore I Vessel Assessment, SIVA). Retinopathy was graded using a standard protocol. Associations were examined using Cox proportional hazards regression models adjusting for age, sex, blood glucose, systolic blood pressure and baseline eGFR.

Results: Over a median follow-up of 6.6 years, 6.4% (70% had diabetes) developed incident CKD and 26.6% (62% had diabetes) developed progressive CKD. In multivariable models, retinal arteriolar narrowing, retinal venular widening, and presence of retinopathy were significantly associated with incident CKD. The HR (95% CI) of incident CKD was 1.31 (1.01-1.72) per SD decrease in arteriolar caliber, 2.20 (1.10-4.41), for tertile 3 vs. tertile 1 of venular caliber; 2.06 (1.24-3.44) for retinopathy. Increased arteriolar tortuosity alone was associated with progressive CKD (1.57 [1.04-2.37] per SD decrease. All associations were consistently present among those with diabetes.

Conclusions: Retinal vascular abnormalities increased the risk of CKD by more than two times in Asian adults. Our findings provide evidence that retinal imaging may be a useful tool to improve risk stratification for CKD.

Relationship Between Serum Bilirubin and Hyalinization of Renal Arterioles Tsuyoshi Miyagi,[1] Kentaro Kohagura,[2] Yusuke Ohya,[1] Kunitoshi Iseki.[2] *[1]Dept of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nshihara-cho, Okinawa, Japan; [2]Dialysis Unit, Univ of the Ryukyus, Nishihara-cho, Okinawa, Japan.*

Background: It has been suggested that there is a relationship between serum bilirubin and microangiopathy. In the present study, we examined the relationship between serum bilirubin levels and the hyalinization of renal arterioles in patients with chronic kidney disease (CKD).

Methods: We reviewed the clinical records of 138 patients with CKD (mean age: 44 years) who underwent renal biopsy at our department during a 3-year period starting in 2010. Patients who were receiving calcineurin inhibitors were excluded. The subjects were divided into three groups based on their total serum bilirubin levels: tertile group 1 (0.2–0.4 mg/dl; 40 patients), tertile group 2 (0.5–0.7 mg/dl; 61 patients), and tertile group 3 (0.8–1.4 mg/dl; 37 patients). Using the pathological specimens obtained from renal biopsies, the hyalinization of renal arterioles was semiquantitatively evaluated, and the mean score of renal arteriolar hyalinization grade was used for analysis.

Results: Tertile group 1 had markedly higher urinary protein levels and markedly lower serum hemoglobin (Hb) levels than tertile group 3. We defined total serum bilirubin levels under 0.5 mg/dl (tertile group 1) as low levels and divided them into two groups of values under and above 0.5 mg/dl. These were set as explanatory factors, and a multiple regression analysis was performed, with the degree of hyalinization of renal arterioles as the objective variable. A low serum bilirubin level was a significant risk factor for the hyalinization of renal arterioles ($R^2 = 0.45$, $\beta = 0.26$, $p = 0.003$), even when adjustments were made for age, sex, HbA1c levels, mean blood pressure, history of smoking, and LDL cholesterol levels. Furthermore, even when the explanatory factor of serum Hb level was added, the results of the analysis remained the same.

Conclusions: Low serum bilirubin levels may be a risk factor for the hyalinization of renal arterioles independent of classical risk factors of cardiovascular disease.

FR-PO546

Autonomic Nervous Dysfunction in Predialytic Chronic Kidney Disease: 3 Years Observational Follow-Up Study Su Min Park, Sang Heon Song, Eun Young Seong, Ihm Soo Kwak, Harin Rhee, Il Young Kim, Woo Jin Jung, Jong Man Park, Dong Won Lee, Soo Bong Lee, Min Jung Kim, Joo Hui Kim. *Internal Medicine, Pusan National Univ School of Medicine, Busan, Republic of Korea.*

Background: Generally, sympathetic overactivity and impairment of the parasympathetic system are often seen in patients with dialytic CKD, COPD, RA as well as elderly. Also, arterial stiffness and edema have been related with mortality in patients with cardiovascular disease. However, to date, few data regarding autonomic nervous system, vascular stiffness, edema in pre-dialytic CKD was proposed. This study was designed to explore the interrelationship of those parameter in pre-dialytic CKD (G3, 4) and uncover the risk factor related with renal functional deterioration.

Methods: Thirty-three patients were enrolled. Hydration status (extracellular water [ECW]/total body water [TBW]) was determined by bioimpedance analysis. Brachial-ankle pulse wave velocity (baPWV) and neck ultrasonography for carotid plaque and intima-media thickness were conducted for checking up of vascular status. CAN was scored using Ewing's method and we also expressed the standard deviation of normal-to-normal interval (SDNN), low frequency/high frequency ratio (LF/HF ratio). Serial serum creatinine change over a median follow-up of 3 years was used for assessment of renal function.

Results: Of the 33 patients, 14 (42%) have suffered with CAN. Patients with CAN have higher progressive declining rate of renal function, baPWV, systolic BP compared with patients without CAN. The group having declining renal function has higher CAN score, baPWV and lower SDNN compared with preserved renal function group. CAN score correlated positively with ECW/TBW (r=0.405, p=0.019), mean PWV (r=0.623, p<0.001) and SBP(r=0.513, p=0.002). CAN score correlated negatively with declining rate of renal function(r=-0.471, p=0.006), Hb(r=-0.659, p<0.001) and albumin(r=-0.484, p=0.004).

Conclusions: Autonomic nervous dysfunction including lower SDNN and increased arterial stiffness including high baPWV may be important risk factors for deterioration of renal function in pre-dialytic CKD patients. Also, autonomic nervous dysfunction was related with arterial stiffness and edema.

FR-PO547

Inhibition of EGFR Alleviates the Development and Progression of Hyperuricemic Nephropathy in Rats Na Liu,[1] Li Wang,[1] Andong Qiu,[2] Shougang Zhuang.[3] *[1]Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China; [2]School of Life Science and Technology, Advanced Inst of Translational Medicine, Tongji Univ, Shanghai, China; [3]Dept of Medicine, Rhode Island Hospital and Brown Univ School of Medicine, Providence.*

Background: Hyperuricemia is an independent risk factor for chronic kidney disease and contributes to kidney fibrosis. In this study, we investigated the effect of epidermal growth factor receptor (EGFR) inhibition on the development of hyperuricemic nephropathy (HN) and the mechanisms involved.

Methods: In this experiment, we did Cell Culture and Treatments, processed the establishment of Hyperuricemic nephropathy (HN) model, assessment of serum uric acid, renal Function and other biochemistry index, performed Immunoblot Analysis, Immunohistochemical Staining, as well as ELISA analysis.

Results: In a rat model of HN induced by feeding a mixture of adenine and potassium oxonate, increased EGFR phosphorylation and severe glomerular sclerosis and renal interstitial fibrosis were evident, accompanied by renal dysfunctionandincreased urine microalbumin excretion. Administration of gefitinib, a highly selective EGFR inhibitor, prevented renal dysfunction, reduced urine microalbumin and inhibited activation of renal interstitial fibroblasts and expression of extracellular proteins. Gefitinib treatment also inhibited hyperuricemia-induced activation of the transforming growth factor-β1 (TGF-β1) and nuclear factor-κB (NF-κB) signaling pathways and expression of multiple profibrogenic cytokines/chemokines in the kidney. Furthermore, gefitinib treatment suppressed xanthine oxidase activity, which mediates uric acid production,andpreserved expression of organic anion transporters 1 and 3, which promotes uric acid excretion in the kidney of hyperuricemic rats.

Conclusions: Thus, blocking EGFR can attenuate development of HN via suppression of TGF-β1 signaling and inflammation, and promotion of the molecular processes that reduce uric acid accumulation in the body.

FR-PO548

Probiotic and Yogurt Consumption Is Associated with a Lower Prevalence of Albuminuria: A Cross-Sectional Analysis of NHANES Rabi Yacoub, Girish N. Nadkarni, Deepak Kaji, Shanti N. Patel, John C. He, Steven G. Coca, Jaime Uribarri. *Medicine/Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Animal data suggest that probiotic supplements may retard CKD progression. Yogurt is the most widely available probiotic food in the United States. However, the relationship between frequent yogurt consumption or probiotic use, and kidney parameters has not yet been evaluated. We aimed to study this association in the National Health and Nutrition Examination Survey (NHANES) database.

Methods: We utilized NHANES data with reported one year yogurt consumption frequency and probiotic use (2003-2005).The "consumers group" was defined as either yogurt consumption ≥ thrice weekly or regular use of probiotic, and we analyzed its association with albuminuria and eGFR after adjustment for demographic and clinical parameters.

Results: We had complete data on 6853 participants (mean age 48.3±20,45.2% male), of which,1559 (20.3%) were frequent consumers and 918 participants (12.2%) had detectable albuminuria (Median=67.1, IQR =41.6-157.1 mcg/mg). Frequent consumers had a trend towards lower mean UACR compared to non-consumers (mean difference [MD]: -12.3, 95% CI -29.8 to 5.2, P=0.17) that was attenuated after complete adjustment. On the other hand, frequent consumers had decreased odds of albuminuria (UACR > 30 mcg/mg) compared to non-consumers (adjusted Odds Ratio 0.79; 95% CI 0.63-0.97; P=0.03).

	Unadjusted			Adjusted ǂ		
	OR	95% CI	P	OR	95% CI	P
Albuminuria	0.69	0.58-0.84	<0.001	0.79	0.63-0.97	0.03
CKD	0.79	0.65-0.96	0.02	0.89	0.69-1.14	0.34
	MD	95% CI	P	MD	95% CI	P
UACR	-12.3	-29.8 to 5.2	0.17	-0.5	-16.9 to 15.9	0.95
eGFR	1.1	-0.3 to 2.6	0.14	0.6	-0.3 to 1.6	0.21

ǂ Gender, age, race, medical history of hypertension and diabetes, socioeconomic status (family income to poverty index), HgbA1c, BMI, insulin, statin, RAAS blockers use and probiotic use duration

Neither CKD III-V prevalence, nor continuous eGFR was significantly different between the consumers and non-consumers.

Conclusions: We observed an inverse association of probiotic/yogurt consumption and albuminuria in a large, nationally representative general population sample. Future studies evaluating the association between probiotic/yogurt use and kidney diseases are warranted.

FR-PO549

Assessment of Serum Levels of Heavy Metals in Patients with Chronic Kidney Disease of Unknown Etiology Om Prakash Kalra,[1] Akash Gupta,[1] Alpana Raizada,[1] Sunil Agarwal,[1] Basu Dev Banerjee.[2] *[1]Medicine, UCMS and GTB Hospital, Delhi, India; [2]Biochemistry, UCMS and GTB Hospital, Delhi, India.*

Background: Chronic kidney disease (CKD) encompasses a wide spectrum of different etiological processes associated with abnormal kidney function and gradual progressive decline in glomerular filtration rate. CKD of unknown etiology (CKDu) has emerged as an important entity accounting for approximately 10% of CKD patients worldwide. Of the environmental toxins implicated in causation of CKDu, heavy metals form an important group. In the present study, we estimated the serum levels of lead, cadmium, arsenic and chromium in patients with CKDu and evaluated their role in the etiopathogenesis of CKDu.

Methods: The study was conducted in the Departments of Medicine and Biochemistry at University College of Medical Sciences and GTB Hospital, Delhi from December 2013 - April 2015. It was a case control, cross sectional study. Ninety subjects in the age group 18 – 60 years of either sex were divided into 3 groups: Group I: Healthy controls (n=30), Group II: Individuals satisfying case definition of CKDu(n=30) and Group III: Individuals having CKD of known etiology (CKDk)(n=30). Detailed history, complete physical examination, routine investigations, urine albumin excretion (UAE) estimation was done. Estimation of serum level of heavy metals was done using Atomic Absorption Spectrophotometery.

Results: The median levels of lead, cadmium and chromium were significantly higher in patients of group II and this difference was statistically significant as compared to subjects of group I and III.The median levels of arsenic in patients of group II and III were similar but significantly higher than patients of group I. The levels of arsenic, cadmium and chromium detected in healthy controls (group I) were negligible. UAE in patients of group II and III were similar but significantly higher than patients of group I.

Conclusions: As compared to healthy controls, the serum levels of lead, cadmium, arsenic and chromium were found to be significantly higher in patients of CKDu. The study indicates a possible role of heavy metals in causation of CKDu.

FR-PO550

High Prevalence of Elevated Molybdenum Levels in CKD Patients Guido Filler,[1,2,3] Vladimir Belostotsky,[4] Marta Caroline Kobrzynski,[1] Shih-Han S. Huang,[1,2] Liju Yang.[3] *[1]Paediatrics, Univ of Western Ontario, London, ON, Canada; [2]Medicine, Univ of Western Ontario, London, ON, Canada; [3]Pathology and Laboratory Medicine, Univ of Western Ontario, London, ON, Canada; [4]Paediatrics, McMaster Univ, Hamilton, ON, Canada.*

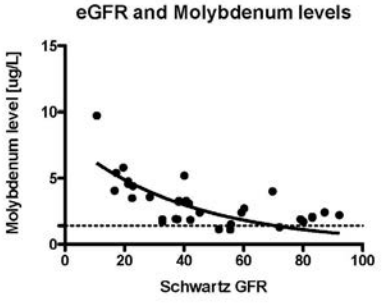
Background: Molybdenum (Mo, atomic number 42) is an essential trace element present in water and is crucial for human survival because four mammalian enzymes harbor a pterin-based Mo cofactor (Moco) at their active site and are Mo-dependent. Mo can be lethal in high doses, and chronic toxicity in animals leads to stunted growth, skeletal abnormalities, anemia, and histological changes in the kidney and liver. There is no information about Mo levels in patients with CKD.

Methods: After approval by the ethics board, and as part of a larger study on zinc supplementation in CKD, we studied 87 plasma Mo and copper (Cu) levels in 50 children with an eGFR < 90 and > 15 mL/min/1.73 m^2 using the Schwartz formula. Where available,

we also recorded the cystatin C eGFR using the Filler formula in 35 children. Mo and Cu levels were measured using High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry (HR-ICP-MS).

Results: The mean Schwartz eGFR was 46±23 and the Cystatin C eGFR was 48±20 mL/min/1.73 m^2. The median Mo level was 2.26 (interquartile range 1.7, 3.3 ug/L, mean 2.78±1.70 ug/L), significantly higher than the upper reference interval of 1.4 ug/L, and with an exponential increase with lower eGFR.

Figure: The relationship between Schwartz eGFR and plasma Mo levels in 39 patients (initial screening time point for zinc study).



The mean Cu level was 1124±378 ug/mL, not significantly different from the reference interval of 822 to 1201 ug/mL. eGFR was significantly negatively correlated with Mo levels (Spearman r = -0.57, p=0.0002).

Conclusions: With worsening kidney function, Mo levels accumulate, while Cu levels remain unaffected.

FR-PO551

High Prevalence of Elevated Vanadium Levels in CKD Patients

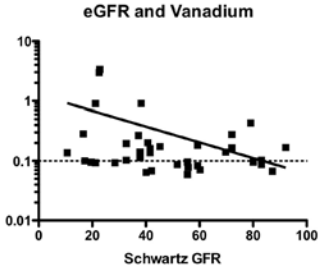
Guido Filler,[1,2,4] Vladimir Belostotsky,[3] Marta Caroline Kobrzynski,[1] Liju Yang.[4] *[1]Paediatrics, Univ of Western Ontario, London, ON, Canada; [2]Pathology and Laboratory Medicine, Univ of Western Ontario, London, ON, Canada; [3]Paediatrics, McMaster Univ, Hamilton, ON, Canada; [4]Medicine, Univ of Western Ontario, London, ON, Canada.*

Background: Vanadium (V, atomic number 23) is an essential trace element present in many industrial products, especially in steel, which can be very toxic if levels are too high.The excretion of vanadium by the kidneys is rapid with a biological half-life of 20-40 hours in the urine. Chronic poisoning is associated with respiratory symptoms, nervous disturbances, vegetative symptoms, tremors, palpitation of the heart, extrasystoles, anemia, leukopenia, and punctate basophilia of the erythrocytes. While adult data suggest that V is accumulating in dialysis patients, there is no information about V levels in patients with CKD.

Methods: After approval by the ethics board, and as part of a larger study on zinc supplementation in CKD, we studied 87 plasma V levels in 50 children with an eGFR < 90 and > 15 mL/min/1.73 m^2 using the Schwartz formula. Where available, we also recorded the cystatin C eGFR using the Filler formula in 35 children. V levels were measured using High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry (HR-ICP-MS).

Results: The mean Schwartz eGFR was 46±23 and the Cystatin C eGFR was 48±20 mL/min/1.73 m^2. The mean V level was 0.117 (interquartile range 0.082, 0.1840 ug/L, mean 0.1170±0.4899 ug/L), significantly higher than the upper reference interval of 0.1 ug/L (p=0.0057), and with a trend towards exponential increase with lower eGFR (r=-0.3075, p=0.0604.

Figure 1: The relationship between Schwartz eGFR and plasma V levels in 50 patients (initial screening time point for zinc study).



Conclusions: We observed a high prevalence of elevated V levels in the CKD patients. With worsening kidney function, V levels accumulate.

Funding: Clinical Revenue Support

FR-PO552

Chronic Nicotine (Ch-Nic) Exacerbates Subpressor Angiotensin II (SP-AngII) Induced Renal Dysfunction in Part via the Renal Sympathetic Nervous System

Kiran B. Chandrashekar,[1] Rodrigo Maranon,[2] Arnaldo F. Lopez-Ruiz,[1] Andrea P. Soljancic,[1] Istvan Arany,[1] Luis A. Juncos.[1] *[1]Nephrology, UMMC, Jackson, MS; [2]Physiology, UMMC, Jackson, MS.*

Background: Ch-Nic exacerbates SP-AngII-induced renal dysfunction and vascular remodeling while having minimal changes on blood pressure. However, the mechanisms are incompletely understood. Because Ch-Nic activates the renal sympathetic nervous system, we hypothesized that this activation contributes to nicotine's deleterious effects on SP-AngII-induced renal dysfunction and injury.

Methods: Sprague Dawley rats underwent either sham or renal denervation (RD) surgery and then subdivided to get nicotine (12 g/ml) or vehicle (saccharine 2%). These were randomized to get either SP-AngII (SQ, 200ng/kg/min) or vehicle (saline). Hemodynamics were measured in anesthetized animals and tissue collected for biochemical analysis.

Results:

	Systolic BP (mmHg)	RVR (ml/min/ mmHg)	Pl. Creatinine (mg/dl)	NGAL UI/mg creat	TGF (ng/µg protein)
Ct+Sham	107± 6	15± 0.7	0.7± 0.02	0.26± 0.03	10± 1
CT+ RD	107± 5	14± 1	0.7± 0.02	0.3± 0.4	9.5± 1
Ch-Nic+ Sham	108± 5	14± 0.2	0.9± 0.03	0.5± 0.06	20± 0.6
Ch-Nic+RD	101± 3	15± 0.7	0.7± 0.04	0.4± 0.02	16± 1.6
SP-AngII+Sham	162± 4*†	23± 1.3*†	2.4± 0.1*†	4.3± 0.4*†	29± 1.3*†
SP-AngII+RD	123± 3*#	17± 0.8#	2± 0.07#†	2.7± 0.2*#†	25± 1.3*†
Sp-AngII+Ch-Nic+Sham	172± 4*#	31± 1.2*#†	3± 0.1*#†	8.3± 0.4*#†	40± 1.4*#†
SP-AngII+CH-NIC+RD	134± 2*†λ	18± 0.2λ	2.4± 0.04*†λ	3.7± 0.3*#†	27± 1.2*#†λ

Conclusions: Renal denervation ameliorated SP-AngII-induced HTN, renal dysfunction, inflammation and injury. While RD did not appear to provide additional benefit to blood pressure control in Ch-Nic+SP-AngII group, it provided protection against the renal effects of Ch-Nic in the SP-AngII rats. These results support a role for the sympathetic nervous system in SP-AngII-induced renal dysfunction, as well as in the exacerbating effect of Ch-Nic on SP-AngII mediated renal dysfunction.

FR-PO553

Elevated Plasma Chymase Is Associated with Risk of Chronic Kidney Disease

Jing Chen,[1,2] L. Lee Hamm,[1] Damodar R. Kumbala,[3] Chung-shiuan Chen,[2] Kevin K. Wu,[2] Swapna G. Kallu,[1] Ravi Siriki,[1] Shilpa Gadde,[1] Arnold B. Alper,[1] Myra A. Kleinpeter,[1] Vecihi Batuman,[1] Eric E. Simon,[1] L. Gabriel Navar,[1] Jiang He.[2,1] *[1]Medicine, Tulane School of Medicine, New Orleans, LA; [2]Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [3]Nephrology, Ochsner Health System, New Orleans, LA.*

Background: Chymase is the primary enzyme that mediates angiotensin II formation independent of angiotensin-converting enzyme and also play a role in activating transforming growth factor-βeta and matrix metalloproteinase-9. Experimental studies suggest that it may cause renal and cardiac fibrosis. However, the association of circulating chymase with chronic kidney disease (CKD) is not well studied.

Methods: We investigated the association of chymase and the risk of CKD in 163 CKD patients and 186 controls without CKD. CKD was defined as estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2 or presence of albuminuria. Multivariable analyses were used to examine the relationship of plasma chymase and CKD.

Results: The multivariable-adjusted medians (interquartile ranges) were 1.6 (1.1, 2.2) in patients with CKD vs. 1.2 (0.7,1.9) pg /mL in controls without CKD (p=0.002 for group difference) after adjusting for age, gender, race, physical activity, smoking, drinking, systolic blood pressure, glucose, low-density lipoprotein cholesterol, body mass index, and history of cardiovascular disease. After adjustment for the above risk factors, the odds ratio for CKD comparing the highest to the lowest tertile of chymase was 2.85 (95% confidence interval, 1.41-5.76).

Conclusions: These data indicate that elevated circulating chymase is associated with risk of CKD.

Funding: Other NIH Support - the National Center for Research Resources, National Institutes of Health, Bethesda, MD.

FR-PO554

Methionine Sulfoxide Reductase A (MsrA) Protects Progression of Kidney Fibrosis After Unilateral Ureteral Obstruction Mi Ra Noh,[1] Jee in Kim,[2] Kwon Moo Park.[1] *[1]Dept of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea.*

Background: Methionine sulfoxide reductase A (MsrA) reduces oxidized methionine and protects cells against oxidative stress. Oxidative stress accelerates kidney fibrosis. Here, we investigated the role of MsrA in unilateral ureteral obstruction (UUO)-induced kidney fibrosis using MsrA gene-deleted mice.

Methods: *MsrA*$^{+/+}$ and *MsrA*$^{-/-}$ male mice were subjected to UUO. Kidneys were harvested 5 days after the UUO surgery.

Results: UUO reduced Msrs expression and activity in the kidney. UUO resulted in expansion of interstitial area with increased collagen deposition. In addition, UUO increased the levels of α-smooth muscle actin and collagen III expression. MsrA deficiency significantly enhanced collagen deposition and expression of those proteins. UUO resulted in the increase of hydrogen peroxide (H_2O_2) formation and lipid peroxide in both *MsrA*$^{+/+}$ mouse kidneys and *MsrA*$^{-/-}$ mouse kidneys, and these increases were significantly higher in *MsrA*$^{-/-}$ mouse kidneys than in *MsrA*$^{+/+}$ mouse kidneys. Furthermore, post-UUO increases in the oxidized glutathione ratio to total glutathione were significantly greater in *MsrA*$^{-/-}$ mouse kidneys than in *MsrA*$^{+/+}$ mouse kidneys. Number of F4/80 expressing cells increased in the kidney after UUO. These increase of F4/80 expressing cells were greater in *MsrA*$^{-/-}$ mouse kidneys than in *MsrA*$^{+/+}$ mouse kidneys. Levels of Ly6G, a marker of granulocyte, were also higher in *MsrA*$^{-/-}$ mouse kidneys than in *MsrA*$^{+/+}$ mouse kidneys.

Conclusions: In conclusion, MsrA protects kidney against UUO-induced fibrosis, suppressing oxidative stress and inflammatory responses.

Funding: Government Support - Non-U.S.

FR-PO555

The Soluble Urokinase-Type Plasminogen Activator Receptor Serum Levels in Adults with Nephrotic Syndrome Qiuling Fan. *Nephrology, The First Hospital of China Medical Univ.*

Background: The serum levels of soluble urokinase type fibrinolytic enzyme activators receptor (suPAR) in adults with nephrotic syndrome were analyzed.

Methods: The serum levels of soluble urokinase type fibrinolytic enzyme activators receptor (suPAR) in 70 nephrotic syndrome patients with membranous nephropathy, diabetic nephropathy group, lupus nephritis, minimal change kidney disease and focal segmental glomerular sclerosis group was detected by enzyme-linked immunosorbent assay. The relationship between the the clinical parameters and suPAR levels were analyzed.

Results: Serum soluble urokinase receptor levels of nephrotic syndrome patients are significantly higher than the normal control group ($P < 0.01$). The serum suPAR levels of FSGS and MN patients were significant higher than MCD patients($P < 0.05$). Serum suPAR level was positively correlated with age, serum creatinine, blood urea nitrogen (rs=0.401 p=0.001;rs=0.286 p=0.016;rs=0.249 p=0.037;rs=0.245 p=0.041;rs=0.247 p=0.039), and negatively correlated with eGFR (rs=-0.265 p=0.026;rs=-0.237 p=0.048;rs=-0.309 p=0.009).

Conclusions: Serum suPAR level was positively correlated with age, serum creatinine, blood urea nitrogen, and negatively correlated with eGFR. The serum suPAR levels of FSGS and MN patients were significant higher than MCD patients and may be a potential marker to distinguish FSGS and MCD.

FR-PO556

Urinary Sodium: Impact on Blood Pressure and Progression of Chronic Kidney Disease Adriano Luiz Ammirati, Maria Eugenia F. Canziani. *Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.*

Background: Chronic kidney disease (CKD) is characterized by chronicity and progression of renal damage. The presence of hypertension is relates to the progression of renal damage. Diets high in salt have been associated with an increased risk of hypertension. Sodium analysis in the urine of 24 h is considered the standard method to estimate the daily intake of this mineral. The aim of this study was to evaluate the impact of sodium intake estimated by urinary sodium in the urine of 24 hours (Nau24hs) on renal outcomes and their impact on hypertension.

Methods: Data were collected from medical records of 118 patients with CKD in conservative treatment, that had one Nau24hs dosage and a follow-up of at least five years. Information collected initially and after 5 years were: demographics, etiology of CKD; comorbidities, blood pressure; routine laboratory tests and estimated creatinine clearance (EPI-CKD). The Nau24hs values were classified into two groups by the median and also divided into tertiles and compared with the rate of progression of CKD (fall of the estimated clearance greater than 20% at 5 years) and the change in blood pressure.

Results: Patients had a mean of 186 ± 64 MEq /L of Nau24hs which represented a high sodium intake (10 grams; 96% of patients with sodium intake greater than 6 grams). Patients with Nau24hs> 170 mEq /L had higher systolic blood pressure and those with Nau24hs> 200 mEq / L had higher systolic and diastolic blood pressure when compared to other patients. In addition, patients with higher Nau24hs present significant decrease in systolic blood pressure over 5 years. The decrease in creatinine clearance over 5 years (29% of patients) were more frequent in diabetics and those who did not use converting enzyme inhibitors and are also associated with the presence of proteinuria. There was no association of Nau24hs with the progression of renal dysfunction.

Conclusions: In patients with stable and low rate of CKD progression urinary sodium was associated with high blood pressure, but was not associated with more pronounced worsening of long-term renal function, probably because these patients were treated more intensively over the pressure control.

FR-PO557

Risk of End-Stage Renal Disease with Longitudinal Change in Filtration Markers Casey Rebholz, Lesley Inker, Yuan Chen, Meredith C. Foster, John H. Eckfeldt, Paul L. Kimmel, Vasan S. Ramachandran, Harold I. Feldman, Chi-yuan Hsu, Andrew S. Levey, Josef Coresh. *Chronic Kidney Disease Biomarkers Consortium.*

Background: Change in estimated glomerular filtration rate (eGFR) based on creatinine has been proposed as a surrogate outcome in clinical trials of chronic kidney disease (CKD). Risk of end-stage renal disease (ESRD) associated with change in other kidney filtration markers has not been previously assessed in chronic kidney disease (CKD) populations.

Methods: We conducted prospective analyses of the Modification of Diet in Renal Disease (MDRD; N=840; mean age 52 years) and African-American Study of Kidney Disease and Hypertension (AASK; N=1,094; mean age 55 years) trials. Creatinine, cystatin C, b_2-microglobulin, and β-trace protein levels were measured in serum samples collected at baseline and at the 24-month follow-up visit and were expressed using CKD-EPI eGFR equations. Multivariable Poisson regression was used to estimate associations between continuous percent change in eGFR for each marker (alone and in combination) with subsequent risk of developing ESRD. Seemingly unrelated regression was used to compare the strength of risk estimates from different models.

Results: In MDRD and AASK, respectively, there were 310 and 161 incident ESRD cases during a median follow-up of 4.7 and 7.1 years. Percent change in eGFR from the four filtration markers was significantly associated with incident ESRD risk (**Table**). The average of percent change in eGFR based on all four filtration markers was more strongly associated with ESRD risk than percent change in eGFR-creatinine alone.

Table. Risk of Incident ESRD Associated with Percent Change in Filtration Markers in MDRD and AASK

Filtration Marker	MDRD		AASK	
	IRR† (95% CI) per 30% decline	P-value	IRR† (95% CI) per 30% decline	P-value
eGFR-Cr	2.09 (1.78, 2.45)	<0.001	3.40 (2.82, 4.10)	<0.001
eGFR-Cys	2.58** (2.11, 3.16)	<0.001	4.33* (3.40, 5.50)	<0.001
eGFR-βTP	3.59*** (2.83, 4.56)	<0.001	6.87*** (5.08, 9.28)	<0.001
eGFR-β_2M	2.55** (2.11, 3.08)	<0.001	3.96 (3.17, 4.94)	<0.001
Average of 4 Markers	2.89*** (2.35, 3.55)	<0.001	4.74*** (3.71, 6.05)	<0.001

AASK, African-American Study of Kidney Disease and Hypertension; β_2M, β_2-microglobin; βTP, β-trace protein; CI, confidence interval; Cr, creatinine; Cys, cystatin C; eGFR, estimated glomerular filtration rate; ESRD, end-stage renal disease; IRR, incidence rate ratio; MDRD, Modification of Diet in Renal Disease

†Adjusted for age, sex, race, body mass index, systolic blood pressure, diabetes, total cholesterol, first eGFR for the respective filtration marker

* p<0.05 from seemingly unrelated regression comparing IRR for the respective marker vs. IRR for eGFR-Cr
** p<0.01 from seemingly unrelated regression comparing IRR for the respective marker vs. IRR for eGFR-Cr
*** p<0.001 from seemingly unrelated regression comparing IRR for the respective marker vs. IRR for eGFR-Cr

Conclusions: Decline in kidney function over two years, assessed using eGFR-creatinine as well as multiple other filtration markers, is associated with ESRD. Novel filtration markers (cystatin C, b_2-microglobulin, β-trace protein) may provide additional information about CKD progression beyond creatinine.

FR-PO558

Validation and Clinical Associations of a Predictive Model for Progression to Renal Replacement Therapy: A Retrospective Cohort Study James Ritchie,[1] Afshan Ahmed,[1] Olivier J. Wouters,[2] Darren Green,[1] Smeeta Sinha,[1] Donal J. O'Donoghue,[1] Philip A. Kalra.[1] *[1]Salford Royal NHS Foundation Trust, United Kingdom; [2]London School of Economics and Political Science, United Kingdom.*

Background: Timely planning for initiation of renal replacement therapy (RRT) is vital. Despite existing, validated risk-prediction models, RRT preparation is often based upon clinical judgment. Here, we consider the benefits of applying an existing model (Tangri et al. JAMA, 2011) in a UK secondary care population.

Methods: Patients with ≥5 years of potential follow-up were identified from the Chronic Renal Insufficiency Standards Implementation Study (CRISIS). 5-year RRT risk was estimated using a logistic regression model incorporating age, gender, eGFR, albuminuria, PO_4, Ca^+, HCO_3 and albumin.

Results: 728 patients were included in this analysis (median follow-up 4.4 [IQR 2.4-5.6] years), with 118 patients (16%) progressing to RRT. Mean baseline age was 64±14 years and eGFR 34±14 ml/min/1.73m^2.

Risk was right skewed, with 328 (45%) of patients having a 5-year risk of <5%. 80 patients (11%) had a 5-year RRT risk of >50%. The overall area under the curve was 0.89. This did not vary by primary disease: glomerulonephritis (0.87); pyelonephritis (0.95); polycystic kidney disease (0.91); and diabetic nephropathy (0.88).

In higher-risk groups, a greater proportion of patients commenced RRT using peritoneal dialysis, and a smaller proportion commenced RRT as an in-patient. The proportion of patients transplant listed at the time of starting RRT was greater in the lower risk group than the higher risk group.

Risk group and number of patients	Number starting RRT	Months to RRT	In-patient start	Transplant eligable / listed	Peritoneal dialysis
LOW: <20% n=538 (73%)	23 (4%)	48(12)	14%	81% / 60%	18%
MEDIUM: 20 - 40% n=91 (13%)	32 (35%)	37(15)	9.5%	77% / 54%	22%
HIGH: >40% n=98 (14%)	64 (64%)	20(14)	5.7%	72% / 49%	30%

Time to RRT presented as mean (standard deviation). Percentages represent the proportion of patients within that risk group.

Conclusions: The risk model performed well in our patient population and was disease agnostic. Further work will consider potential causes of the differences in modality and in-patient starts between risk groups.

FR-PO559

Do Electronic Health Records Contain Enough Information to Calculate End-Stage Renal Disease Risk Scores?

C. Blake Cameron,[1] Benjamin Neely,[2] Mark Dakkak,[1] Uptal D. Patel,[1,2] L. Ebony Boulware.[1] *[1]Duke Univ School of Medicine; [2]Duke Clinical Research Inst, Durham, NC.*

Background: Physicians often can't predict which patients with CKD will progress to end-stage renal disease (ESRD) in the near future, contributing to poor outcomes and expensive care. It is unknown to what extent validated ESRD prediction models can be applied to real-world electronic health records (EHRs) for use by population health management programs to target those at greatest risk for renal progression.

Methods: We characterized EHR availability of laboratory results (urine albumin-to-creatinine ratio and serum albumin, bicarbonate, calcium, and phosphorous) required for use in a validated ESRD risk prediction model at Duke University. We identified outpatients with at least two eGFR results, and we defined CKD as the presence of at least two eGFR results <60 mL/min/1.73m^2 separated by ≥90 days.

Results: Among 151,097 eligible patients, the median age was 59.4 years, 85,533 (56.6%) were female, 45,425 (30.1%) were African-American, and 31,581 (20.9%) had evidence of CKD stages 3-5. Few CKD patients had results for urine albumin-to-creatinine ratio (n=3,487, 11.0%) or serum phosphorus (n=9,696, 30.7%), but more had serum albumin (n=28,192, 89.3%), bicarbonate (n=24,650, 78.1%), or calcium (n=31,463, 99.6%) results. Although more lab results were available among patients with worse CKD (p<0.001), the full set of results needed to calculate ESRD risk were available for only a few (n=1,407, 4.5%) patients.

Result Availability	GFR <15 (n=2,061)	GFR 15-29 (n=3,909)	GFR 30-44 (n=10,144)	GFR 45-59 (n=15,467)
Serum phosphorous	1,695 (82.2%)	2,048 (52.4%)	3,088 (30.4%)	2,865 (18.5%)
Urine ACR	157 (7.6%)	570 (14.6%)	1,302 (12.8%)	1,458 (9.4%)
All 5 results present	123 (6.0%)	393 (10.1%)	551 (5.4%)	340 (2.2%)

Conclusions: Few patients with CKD had the full set of laboratory results needed to employ a validated ESRD risk prediction model for population health management. Urine ACR and serum phosphorous results were often unavailable. To improve risk stratification, efforts are needed to more frequently obtain these laboratory tests during clinical care or to develop refined models that use more readily available information.

FR-PO560

Effect and Safety of Sofosbuvir (SOF) Containing Direct-Acting Antiviral (DAA) Hepatitis C Virus (HCV) Therapy in a Real-World Population with Chronic Kidney Disease (CKD)

Guillermo Ortiz,[1] Gregory L. Hundemer,[1] Elke Backman,[2] Ravi I. Thadhani,[1] Raymond T. Chung,[3] Meghan E. Sise.[1] *[1]Nephrology Div, MGH, Boston, MA; [2]Pharmacy, MGH, Boston, MA; [3]Gastrointestinal, MGH, Boston, MA.*

Background: Early trials of SOF-based regimens excluded patients with CKD, thus little is known about safety, efficacy, and effect on kidney function.

Methods: We retrospectively evaluated 72 patients with CKD starting DAA treatment (tx) between 11/2013-12/2014. CKD was defined by average eGFR <60mL/min or albuminuria >30mg/g 6 months prior to tx. Safety, tolerability and laboratory results were assessed by chart review. Models predicting sustained virological response (SVR) were performed.

Table 1: Logistic regression model predicting SVR (n=61)

	Univariate		Multivariable	
BL Predictors	**OR (95% CI)**	**P Value**	**OR (95% CI)**	**P Value**
Age, per 10 years	1.25 (0.58,2.67)	0.57	0.68 (0.16,2.85)	0.60
Female	3.10 (0.62,15.55)	0.17	4.20 (0.41,43.45)	0.23
Black	0.44 (0.11,1.79)	0.25	0.22 (0.03,1.62)	0.14
HCV Genotype 3	0.08 (0.01,0.84)	0.04*	0.07 (0.00,5.56)	0.23
Early discontinuation	0.11 (0.02,0.69)	0.02*	0.06 (0.00,0.90)	0.04*
Cirrhosis	1.85 (0.51,6.77)	0.35	1.00 (0.17,5.89)	1.00
Prior HCV tx	0.58 (0.17,1.99)	0.39	1.17 (0.20,6.88)	0.87
Liver or kidney transplant	1.02 (0.29,3.54)	0.98	0.34 (0.04,2.69)	0.31
Baseline eGFR, per 10 ml/min decrease	1.79 (1.27,,2.50)	<0.01*	2.10 (1.22,3.63)	0.01*

Results: Subjects were aged 61±8 years, 60% white, 22% black, 12% Hispanic, and 74% male. 50% were diabetic, 39% cirrhotic, 54% HCV tx naïve, 39% had prior liver or kidney transplant, and 7% were HIV/HCV coinfected. DAA regimens were: SOF/simeprevir 50%, SOF/ledipasvir 13%, SOF/ribavirin 28%, other SOF regimens 10%. 8% had a transient creatinine rise ^{3}0.5mg/dL during tx. Average eGFR on tx was similar to baseline [mean (95% CI): 57 (52-62) vs. 58 (53 – 63) mL/min, respectively P=0.26]. SVR was 77% (95% CI 66-88). 76% experienced at least 1 adverse effect (AE); only 5 (7%) discontinued tx due to an AE.

Conclusions: SOF-containing DAA regimens are effective and relatively safe in patients with CKD. Although AEs were common, serious AEs or significant nephrotoxicity were rare. Lower eGFR at baseline predicted an increase likelihood of HCV cure with SOF-based regimens.

FR-PO561

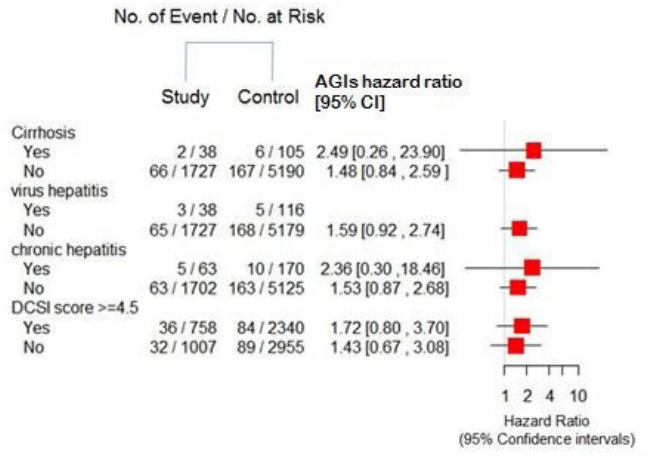
Risk of Liver Injury Afterα-Glucosidase Inhibitors Therapy in Advanced Chronic Kidney Disease Patients: A Population-Based Study

Vincent Wu,[1] Chih-chin Kao,[2] Taomin Huang.[1] *[1]Internal Medicine, National Taiwan Univ Hospital, Taipei; [2]Internal Medicine, Taipei Medical Univ Hospital.*

Background: α-glucosidase inhibitors (AGIs) are commonly used to control postprandial blood glucose. However, AGIs-related liver injury has been reported, but whether the relationship of AGIs and liver injury applies to advanced chronic kidney disease (CKD) patients remains uncertain.

Methods: In the nationwide case-control study, we recruited advanced diabetic CKD patients, who has taken AGIs from January 1, 2000 through December 31, 2010 as cases and matched 5295 matched controls. Recent and former AGIs users were defined as patients who received the AGIs prescription 30-60 days and 30-210 days before the event of liver injury. The risk of AGIs-related liver injury was examined via time-dependent cox proportional hazards model and stratified analysis.

Results: The age of enrollee is 63 ± 11 years and nearly 51% is men. Liver injury developed in 3.9% of cases and 3.3% of control patients. Patients who received insulin treatment (p=0.03), had chronic liver disease (p=0.01) were predictive to liver injury. AGIs use did not increase the risk of liver injury in advanced CKD patients (p= 0.22), both among recent users (*P=0.28*) or former users (*P=0.22*). The stratified analysis showed no increased risk of liver injury in virus hepatitis, liver cirrhosis, subsequent end stage renal disease or patients who has diabetic related comorbidities. (all p> 0.05) .



Conclusions: Available evidence supports expansion of AGIs use in patients with advanced CKD, without increased risk of liver injury. Neither accumulated dose- dependent effect of AGIs, or subsequent ESRD will aggravated AGIs-associated liver injury. Further randomized controlled trials are warranted to confirm our results.

Add-On Renoprotective Effect of Pentoxifylline in Pre-Dialysis Advanced Chronic Kidney Disease Treated with Renin-Angiotensin-Aldosterone System Blockade – A Nationwide Database Analysis

Ko-Lin Kuo,[1] Szu-Chun Hung,[1] Jia-sin Liu,[2] Der-Cherng Tarng.[3] *[1]Taipei Tzu Chi Hospital, Taiwan; [2]National Health Research Insts, Taiwan; [3]Taipei Veterans General Hospital, Taiwan.*

Background: Pentoxifylline decreases proteinuria in patients with glomerular disease due to its anti-inflammatory and anti-fibrotic properties. A combination therapy of pentoxifylline with an angiotensin converting enzyme inhibitor (ACEI) or an angiotensin II receptor blocker (ARB) decreased proteinuria and the glomerular filtration rate (GFR) decline in early chronic kidney disease (CKD). Whether adding pentoxifylline to ACEI/ARB provides additional benefits on renal outcome or survival is unclear in CKD stage 5 patients who have not yet received dialysis (CKD 5 ND).

Methods: A prospective cohort study was conducted based on the Taiwan National Health Insurance Research Database. From January 1, 2000 to June 30, 2009, we enrolled 14,117 CKD 5 ND patients with serum creatinine levels >6 mg/dL and hematocrit levels <28% and who have been treated with ACEI/ARB.All patients were further divided into two groups with or without pentoxifylline within 90 days after starting erythropoiesis-stimulating agent therapy (index date). Patient follow-up took place until dialysis, death before initiation of dialysis or December 31, 2009.

Results: With a mean follow-up of 12 months, 9,867 patients (69.9%) required long-term dialysis and 2,805 (19.9%) died before progression to end-stage renal disease requiring dialysis. After propensity score-matching, add-on use of pentoxifylline was associated with a lower risk for long-term dialysis or death in those treated with ACEI/ARB (HR, 0.94; 95% CI, 0.90-0.99) or ARB alone (HR, 0.91; 95% CI, 0.85-0.97).

Conclusions: Pentoxifylline exhibited an add-on renoprotective effect in reducing the risk for long-term dialysis in CKD 5 ND patients who received renin-angiotensin-aldosterone system blockade. Randomized studies are needed to validate this association.

FR-PO563

Novel Therapy Regimens Have Reduced the High Risks of Bladder and Haematological Malignancies in ANCA-Associated Vasculitis

Chinar Rahmattulla,[1] Annelies Evaline Berden,[1] Sophie-charlotte Wakker,[1] Marlies Reinders,[1] Ernst C. Hagen,[2] Ron Wolterbeek,[1] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Leiden Univ Medical Center; [2]Meander Medical Center Amersfoort.*

Background: The introduction of immunosuppressive therapy has dramatically improved the prognosis of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). As a result, attention has shifted to long-term complications in patients. In this study, we investigate the incidence of malignancies in AAV patients. Additionally, we investigate the effect of therapy on malignancy incidence.

Methods: We included patients with histopathologically-proven AAV diagnosed at a large university hospital. Malignancy incidence was assessed with the Dutch National Pathology Database, which covers all the histologically confirmed malignancies diagnosed in The Netherlands. We used the Netherlands Cancer Registry incidence rates for comparing the malignancy incidence in our AAV cohort to that of the general Dutch population.

Results: Thirty-six of 138 patients with AAV developed a total of 85 malignancies during a mean follow-up of 9.7 years. We observed 61 non-melanoma skin cancers (NMSCs), three colon carcinomas, three breast carcinomas, three prostate carcinomas, two lung carcinomas, two soft tissue sarcomas, two unknown primary malignancies, and a variety of malignancies that occurred only once. The gender-, age-, and calendar year-adjusted malignancy risk was 2.21-fold (95%CI: 1.64–2.92) higher than that of the general population. Only the incidence of NMSCs was significantly increased compared to the general population (standardized incidence ratio: 4.23, 95%CI: 2.76–6.19). Malignancy risk was associated with the duration of cyclophosphamide therapy, and was not increased in patients that received cyclophosphamide for less than 1 year.

Conclusions: AAV patients have a higher risk of malignancies than the general population, but this risk is accounted for solely by NMSCs. Throughout the years, the risk of other malignancies – specifically bladder and haematological malignancies – has decreased in patients with AAV. This finding reflects the beneficial results of ongoing efforts to reduce cyclophosphamide exposure by developing new therapy regimens.

FR-PO564

Effect of Lowering LDL-Cholesterol with Simvastatin plus Ezetimibe on Non-Vascular Outcomes in Patients with Chronic Kidney Disease (CKD): Results from the Study of Heart and Renal Protection (SHARP)

Christina A. Reith, Natalie Staplin, William G. Herrington. *On behalf of the SHARP Collaborative Group. CTSU, Univ of Oxford.*

Background: The Study of Heart and Renal Protection (SHARP) was a randomized placebo-controlled trial of LDL cholesterol (LDL-C)-lowering among 9270 patients with CKD which showed that combination therapy with ezetimibe 10mg/ simvastatin 20mg (E/S) reduced vascular events with no significant adverse effects on muscle, hepatobiliary outcomes or cancer. However, assessment of the effects of lowering LDL-C on other non-vascular outcomes has not been extensively explored in patients with CKD.

Methods: All post-randomization serious adverse events (SAEs) were routinely recorded. Post-hoc intention-to-treat analyses were performed of the effect of allocation to treatment on time to first non-vascular SAE by system of disease with sub-categories.

Results: During 4.9 years' median follow-up, similar numbers of participants in the two groups experienced non-vascular SAEs overall (3533 [76.0%] E/S vs 3505 [75.9%] placebo; risk ratio [RR] 1.00, 95% CI 0.95-1.05). After due allowance for multiplicity, there was no evidence of any significant hazard of E/S on non-vascular SAEs by system of disease. Within the class of endocrinology SAEs, there were no significant effects of E/S on any particular individual category of SAE: new-onset diabetes (172 [4.8%] E/S vs 162 [4.5%] placebo; RR 1.06, 95% CI 0.86-1.32 among 3596 vs 3580 participants without diabetes at baseline), diabetes-related complications (136 [2.9%] E/S vs 126 [2.7%] placebo; RR 1.08, 95% CI 0.84-1.37), and other endocrine disorders (58 [1.2%] E/S vs 39 [0.8%] placebo; RR 1.47, 95% CI 0.99-2.19).

Figure: Effect of ezetimibe/simvastatin on non-vascular serious adverse events

	Ezetimibe/simvastatin (n=4650)	Placebo (n=4620)	Risk ratio (95% CI)	p value
Cancer	466 (10.0%)	461 (10.0%)	1.01 (0.88-1.14)	0.94
Renal	2329 (50.1%)	2354 (51.0%)	0.97 (0.92-1.03)	0.34
Respiratory	730 (15.7%)	723 (15.6%)	1.01 (0.91-1.12)	0.91
Hepatobiliary	187 (4.0%)	184 (4.0%)	1.01 (0.83-1.24)	0.91

FR-PO565

Association of β-Blocker Therapy with Renal Outcomes in CKD Patients without prior Cardiovascular Disease

Naohiko Fujii,[1] Takayuki Hamano,[2] Yoshitsugu Obi,[3] Yoshitaka Isaka.[2] *[1]Univ of Pennsylvania, Philadelphia, PA; [2]Osaka Univ, Suita, Osaka, Japan; [3]Univ of California, Irvine, Irvine, CA; [4]Osaka General Hospital, Osaka, Japan.*

Background: Sympathetic overactivity due to impaired kidney function can deteriorate hypertension, renal failure, and cardiovascular disease (CVD) among CKD patients. Mortality benefit of its antagonist, β-blocker (BB), has been shown in patients with prior CVD; however, such evidences are scarce in CKD patients without CVD. Our aim is to evaluate the association between BB and renal outcomes in such patients.

Methods: We extracted 340 predialysis CKD patients without prior CVD but with drug information at baseline from a Japanese CKD cohort (OVIDS-CKD, N=738). The primary

endpoint was a composite of Cr doubling, initiation of RRT, and death. We performed Cox proportional hazards analyses to estimate the hazards ratio (HR) of BB use at baseline adjusting for other parameters, such as age, sex, eGFR, proteinuria, diabetes, BMI, blood pressure, the number of anti-hypertensive drugs, ACEI/ARB use, Hb, Alb, corrected Ca, iP, and FGF23. We also employed 1:k (k = 1-6) propensity-score full matching, where one BB user matched to at most k non-users.

Results: BB users showed significantly-lower eGFR, more proteinuria, higher BMI, more anti-hypertensive drugs, lower Alb, higher 1-84 PTH, higher FGF23, and lower 25OHD levels, most of which suggested a poor risk for CVD at baseline. During a median follow-up of 4.4 years, 109 patients reached the outcome. Of those, 12 patients died before RRT, 71 reached a doubling of Cr, and 26 started dialysis. A multivariable Cox model with covariates that were significantly-different between BB users and non-users at baseline showed non-significant HR of 1.58 (C.I. 0.86 – 2.90). We also evaluated a fully-adjusted model and a parsimonious model with a stepwise backward-elimination method; however, the results remained non-significant. The 1:k (k=1-6) full matching using propensity score did not show significant results, either. (0.93 (0.52 – 1.68)).

Conclusions: The BB therapy was not associated with renal outcomes in CKD patients without prior CVD. Confirmation in a larger study is required.

***Lactobacillus plantarum* 299v Reduces the Incidence of *Clostridium difficile* Infection in Patients Treated with Antibiotics in the Nephrological and Transplantation Department**

Marcin Adamczak, Agata Kujawa-Szewieczek, Katarzyna Kwiecien, Sylwia Malgorzata Dudzicz, Magdalena Gazda, Andrzej Wiecek. *Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland.*

Background: Lactobacillus plantarum 299v (LP299v) has been introduced into the clinical practice in order to reduce gastrointestinal symptoms during antibiotic exposure. However it remains controversial whether or not probiotics are also effective in the prevention of Clostridium difficile infections (CDI) among patients receiving antibiotics. The aim of this clinical, retrospective, single-centre study was to analyze the C.difficile infections among patients receiving antibiotics and hospitalized in the period before and after initiation of LP299v routine use, as a prevention of CDI, in the nephrology and transplantation ward.

Methods: Among 3533 patients hospitalized in Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia in Katowice during two years (October 2012 – October 2013 and December 2013 – December 2014) 23 patients with CDI were diagnosed and enrolled in this study. Since November 2013 prevention of C. difficile infection with the oral use of LP299v was performed in all patients treated with antibiotics and who were at a high risk of developing CDI (patients after organ transplantation and receiving immunosuppressive drugs for any other reasons). For the further analysis the observation period was divided into two twelve-months intervals before (October 2012 to October 2013) and after initiation of LP299v use as the prophylactic manoeuvre against CDI (December 2013 to December 2014).

Results: It was found a significant (p=0.0001) reduction of the number of cases of C. difficile infection after beginning of LP299v routinely used (n=2; 0.11% of all hospitalized patients) compared with the previous twelve-months period of observation (n=21; 1.21% of all hospitalized patients).

Conclusions: Routine use of Lactobacillus plantarum 299v during treatment with antibiotics may prevent C. difficile infection, particularly in patients at high risk of CDI in the nephrology and transplantation ward.

FR-PO567

In Patients with Chronic Kidney Disease, Comanagement by Nephrologists Is Associated with Lower Risk of Medication Errors

Justin XG Zhu, Danielle Marie Nash, Eric Mcarthur, Alexandra Farag, Amit X. Garg, Arsh Jain. *London Health Sciences Centre, London, ON, Canada.*

Background: Patients with chronic kidney disease (CKD) are commonly prescribed drug doses that are excessive for their kidney function. Many CKD patients are followed solely by a family physician. We wish to determine whether care by both a nephrologist and family physician (i.e. comanagement) versus family physician alone is associated with lower risks of inappropriate antibiotic dosing in patients with stage 4 or 5 CKD.

Methods: A retrospective case-control study was conducted, among individuals aged >66 years, with estimated glomerular filtration rate (eGFR) <30 mL/min/1.73 m^2 using linked healthcare databases from 2003-2014. Cases were antibiotic prescriptions dosed inappropriately, whereas controls were prescriptions dosed appropriately. Exposure was comanagement, defined as at least one outpatient visit with a nephrologist in the 1 year prior to antibiotic prescription. A multivariable logistic regression model was used to determine the independent association between comanagement and inappropriate dosing.

Results: Of 21,848 eligible prescriptions studied, 64% were inappropriately dosed. The patients were 82 (IQR 76-87) years of age with comorbidities including: hypertension (89%), diabetes (49%), coronary artery disease (49%), and congestive heart failure (38%). 77% of all prescriptions were prescribed by family physicians and 2% were prescribed by nephrologists. Multivariable analysis revealed that patients with appropriate prescriptions were more likely to have seen a nephrologist in the one year prior with an unadjusted odds ratio of 1.07 (95% CI 1.01-1.14, p=0.02), adjusted odds ratio 1.23 (95%CI 1.15-1.32, p<0.001).

Conclusions: In patients with stage 4 or 5 CKD prescribed an antibiotic, those with an appropriate dose were 23% more likely to have been cared for by a nephrologist in the previous year. Although we cannot conclude what caused the improved prescribing practice, this improvement may, in part, explain the improved patient outcomes associated with seeing a nephrologist in observational studies.

FR-PO568

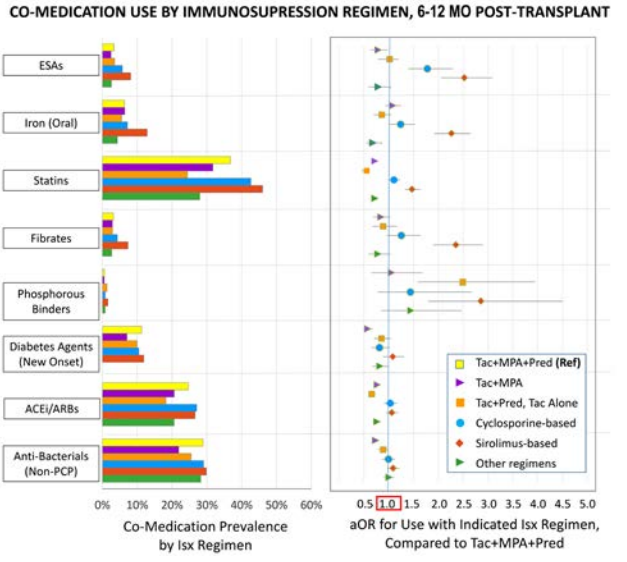
Variation in Co-Medication Use According to Kidney Transplant Immunosuppressive Regimen: Application of Integrated Registry and Pharmacy Claims Data

Krista L. Lentine,[1] Abhijit S. Naik,[2] Mark Schnitzler,[1] David A. Axelrod,[3] Jiajing Chen,[1] Daniel C. Brennan,[4] Dorry L. Segev,[5] Bertram L. Kasiske,[6] Vikas R. Dharnidharka.[4] *[1]Saint Louis Univ; [2]Univ Michigan; [3]Dartmouth; [4]Washington Univ; [5]Johns Hopkins; [6]Univ Minnesota.*

Background: While modern immunosuppressive therapies (ISx) have substantially reduced acute rejection, ISx medications have many side effects, and transplant recipients must take an array of "co-medications" to help mitigate complications. Co-medication utilization patterns are not well described in large, representative samples due to lack of available data.

Methods: We integrated national U.S. transplant registry data with pharmacy records (2005-2010) from a large pharmaceutical claims clearinghouse to examine treatments for anemia, metabolic disorders and infections according to ISx regimen in mo 6-12 post-transplant (N=22,453). Associations of ISx with co-medication use (adjusted odds ratio, aOR) were examined with multivariate logistic regression including adjustment for recipient, donor and transplant factors.

Results: Compared to a reference regimen of tacrolimus (Tac), mycophenolate (MPA) and prednisone, rapamycin-based ISx was associated with significantly (P<0.05) higher use of ESAs (aOR 2.52), iron (aOR 2.26), statins (aOR 1.47), fibrates (aOR 2.35), and phosphorous binders (aOR 2.85) (**Figure**). Cyclosporine-based ISx was associated with more common use of anemia treatments. Compared to those taking triple ISx, recipients of tacrolimus-based dual and mono-therapies had lower use of statins, ACEi/ARBs, and anti-bacterial agents. Recipients of steroid-free ISx were less commonly treated for new onset diabetes.



Conclusions: Alternate ISx regimens are associated with varying treatment requirements for hematologic, metabolic and infectious complications. Co-medication use should be considered in the cost-effectiveness and individualization of ISx regimens.

Association of Urinary Biomarkers of Injury and Repair with Incident Chronic Kidney Disease in Type 2 Diabetes: An Ancillary Study of the ACCORD Trial

Girish N. Nadkarni,[1] Veena Rao,[2] Faramarz Ismail-beigi,[3] Vivian A. Fonseca,[4] Sudhir V. Shah,[5] Michael S. Simonson,[3] Prasad Devarajan,[6] Chirag R. Parikh,[2] Steven G. Coca.[1] *[1]Mount Sinai; [2]Yale Univ; [3]Case Western Reserve Univ; [4]Tulane Univ; [5]UAMS; [6]Univ of Cinncinnati.*

Background: Urinary kidney injury molecule (KIM)-1, monocyte chemoattractant protein (MCP)-1, interleukin (IL)-18, & YKL-40 are biomarkers representing renal injury, inflammation and fibrosis. We evaluated their association with incident CKD3b in the ACCORD trial.

Methods: We designed a case-cohort study of 721 participants & measured KIM-1, MCP-1, IL-18, and YKL-40 on baseline urine samples with Mesoscale platform. Biomarker associations with CKD3b were modeled continuously & by tertiles using Cox proportional hazards models.

Results: Mean age was 62 , 51% were female & baseline eGFR was 88 ml/min. There were 159 incident CKD3b events over median(IQR) of 4.2(3.9-4.7) years. Top tertiles of all biomarkers had higher proportions of incident CKD3b. After adjusting for demographics,

clinical characteristics, baseline eGFR & UACR, highest tertiles of uMCP1 & uKIM1 had adjusted HRs of 1.82(95% CI 1.18-2.81) & 1.51(95% CI 1.01-2.27) respectively. Area under ROC improved from 0.70(with eGFR & UACR) to 0.72 with addition of uMCP1 & uKIM1($p<0.05$). No association was seen for urinary IL-18 & YKL-40.

	Events	Adjusted HR(95% CI)
MCP1		
<=116	36	Ref
117-253	62	1.85(1.23-2.81)
>=254	61	1.90(1.26-2.88)
Per log increase	NA	1.23(1.06-1.44)
IL18		
<=26	49	Ref
27-60	62	1.22(0.82-1.80)
>=60	48	1.07(0.70-1.64)
Per log increase	NA	1.09(0.92-1.28)
KIM-1		
<=586	42	Ref
587-1549	54	1.38(0.91-2.10)
>=1550	63	1.51(1.01-2.27)
Per log increase	NA	1.14(0.98-1.32)
YKL40		
<=197	54	Ref
198-682	61	1.38(0.94-2.02)
>=673	44	0.95(0.62-1.44)
Per log increase	NA	0.97(0.89-1.06)
Baseline Covariates:Age; Sex; Ethnicity; eGFR, UACR, MAP, BMI; cardiac history; ACEI/ARB use; smoking; HbA1C; intensive diabetes control and duration		

Conclusions: Urinary levels of MCP1 and KIM1 are independently associated with incident CKD3b & marginally added to risk prediction after accounting for clinical variables including eGFR/albuminuria.

Association of Tenofovir Disoproxil Fumarate Exposure with Urine α1-microglobulin, a Biomarker of Proximal Tubule Dysfunction

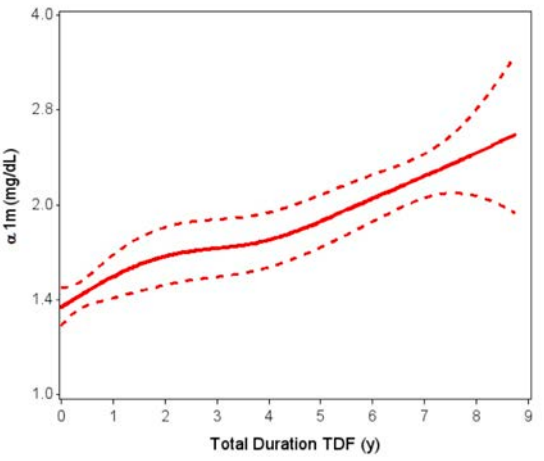
Vasantha Jotwani,[1] Rebecca Scherzer,[1] Michelle M. Estrella,[2] Chirag R. Parikh,[3] Joachim H. Ix,[4] Michael Shlipak.[1] *[1]UCSF; [2]Johns Hopkins; [3]Yale; [4]UCSD.*

Background: Tenofovir disoproxil fumarate (TDF) is a well-recognized contributor to HIV-related kidney disease, via proximal tubular injury. Urine α1-microglobulin (α1m), a low molecular weight protein indicative of proximal tubule dysfunction, may enable earlier detection of TDF-associated toxicity.

Methods: In this cross-sectional study of 883 HIV-infected men enrolled in the Multicenter AIDS Cohort Study, we evaluated associations of TDF exposure with urine α1m levels, using multivariable generalized gamma regression models to adjust for traditional and HIV-related risk factors.

Results: Mean age was 52 and mean eGFR was 90 ml/min/1.73m^2. Median TDF exposure duration was 4.2 years (IQR:2.3,6.1) among the 573 (65%) current and 112 (13%) former TDF users. Cumulative TDF duration was linearly associated with higher urine α1m levels ($p<0.0001$).

Figure: Association of cumulative TDF exposure with urine α1m levels



In adjusted analyses, each year of TDF exposure was associated with 8% higher urine α1m, a 4-fold effect size relative to age (2% per year). Compared with men who never received TDF, α1m levels were 43-50% higher in former and current TDF users. Time since last TDF exposure was only modestly associated with lower α1m.

Adjusted associations of TDF exposure with urine α1m levels

TDF Exposure	% Estimate[1] (95%CI)	P Value
Cumulative TDF exposure (per year)	8 (6,11)	<0.001
Current vs never TDF use	50 (25,80)	<0.001
Past vs never TDF use	43 (11,84)	0.006
Duration off TDF (per year)	-3 (-8,4)	0.41

[1]Estimated % difference in α1m attributable to each TDF exposure variable, adjusted for demographics, traditional kidney risk factors, and HIV-related factors

Conclusions: In HIV-infected men, TDF exposure was strongly associated with higher urine α1m levels. α1m is a promising biomarker for the detection and monitoring of TDF-associated tubular toxicity.

FR-PO571

Impact of Kidney Function and Urinary Protein Excretion on Pulmonary Function

Yusuke Nakade,[1,3] Tadashi Toyama,[2] Shinji Kitajima,[2] Yasuyuki Shinozaki,[2] Akinori Hara,[2] Miho Shimizu,[2] Yasunori Iwata,[2] Norihiko Sakai,[2] Kengo Furuichi,[2] Takashi Wada.[1,2,3] *[1]Clinical Laboratory, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; [2]Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; [3]Dept of Laboratory Medicine, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.*

Background: Although the cardiorenal relationship in patients with chronic kidney disease (CKD) has been investigated, information about the lung-kidney relation is limited. Here, we investigated the impacts of kidney function and urinary protein excretion on pulmonary dysfunction.

Methods: The data of pulmonary function tests (PFTs) and kidney function tests from 1 April 2005 to 30 June 2010 were selected from our laboratory database. Data were classified into 4 categories according to eGFR and proteinuria. Category 1: eGFR ≥ 60 ml/min/1.73 m^2 and urinary protein < 0.3 g/gCr; Category 2: eGFR < 60 ml/min/1.73 m^2 and urinary protein < 0.3 g/gCr; Category 3: eGFR ≥ 60 ml/min/1.73 m^2 and urinary protein ≥ 0.3 g/gCr; Category 4: eGFR < 60 ml/min/1.73 m^2 and urinary protein ≥ 0.3 g/gCr. Pulmonary function data were evaluated according to these 4 categories.

Results: A total of 133 participants without major respiratory disease, abnormal computed tomography and smoking history were enrolled. Hb-adjusted $\%DL_{CO}$ in category 4 (46.2 ± 7.5) and category 2 (63.6 ± 17.8) were significantly lower than that in category 1 (75.8 ± 18.9) ($P < 0.05$). Hb-adjusted $\%DL_{CO}$ was strongly correlated with eGFR in participants with urinary protein ≥ 0.3 g/gCr ($R = 0.81$, $P < 0.001$). In addition, eGFR was associated with Hb-adjusted $\%DL_{CO}$ ($P = 0.023$) and urinary protein tended to be associated with Hb-adjusted $\%DL_{CO}$ ($P = 0.095$) after adjusting for physical features and the presence or absence of DM and Hypertension.

Conclusions: This study suggests that eGFR and urinary protein excretion were associated with pulmonary function (Hb-adjusted $\%DL_{CO}$).

FR-PO572

Renal Biomarkers in Diabetes, Role Beyond Nephropathy, Relation to Retinopathy Mohamed E. Elraggal,[1] Ahmed Fathy Elkeraie,[2] Ahmed M. Abdelhadi,[3] Ashraf Nabiel Abdalla.[4] *[1]Nephrology, Kidney and Urology Center, Alexandria, Egypt; [2]Nephrology, Alexandria Univ, Alexandria, Egypt; [3]Ophthalmology, Alexandria Univ, Alexandria, Egypt; [4]Pharmacology, Umm Al-Qura Univ, Saudi Arabia.*

Background: Diabetic nephropathy and retinopathy remain two of the most frequent complications of diabetes and is the leading cause of end-stage renal disease (ESRD) and blindness worldwide. The concordance rate between both complications is often present in diabetic patients.

Methods: We tried to study the relation between renal biomarkers including serum creatinine (SCr), urinary albumin/creatinine ratio (ACR), serum cystatin-C (cysC) and urinary NGAL (uNGAL) with diabetic retinopathy (DR) in 100 diabetic patients. Patients were classified according to severity into 3 stages: no diabetic retinopathy (No DR), Non-Proliferative DR (NPDR) and proliferative DR (PDR).

Results: Urinary ACR, serum cysC and uNGAL were higher significantly among patients with DR (NPDR & PDR) than patients without, while SCr showed a non significant rise with progression of retinopathy. All markers were higher among PDR than NPDR group.

	No DR	NPDR	PDR	P
SCr (mg/dl)				
Mean ± SD	0.86 ± 0.14	0.96 ± 0.31	1.13 ± 0.49	0.175
Urinary ACR (mg/g)				
Mean ± SD	34.54 ± 55.59	87.43 ± 93.27	118.48 ± 122.75	<0.001*
P between each stage	p1<0.001*, p2= 0.003*, p3= 0.184			
Serum cysC (mg/L)				
Mean ± SD	0.73 ± 0.19	0.89 ± 0.31	1.0 ± 0.43	0.043*
P between each stage	p1= 0.041*, p2= 0.017*, p3=0.358			
uNGAL (ng/ml)				
Mean ± SD	11.14 ± 9.1	22.6 ± 23.79	26.07 ± 23.96	0.016*
P between each stage	p1= 0.033*, p2= 0.013*, p3=0.622			

p_1: p value for comparing between No DR and NPDR
p_2: p value for comparing between No DR and PDR
p_3: p value for comparing between NPDR and PDR
Statistically significant at $p \leq 0.05$

Conclusions: Renal biomarkers namely urinary ACR, serum cysC and uNGAL may point to a more advanced stage of diabetic retinopathy, which might be an aid to identify the degree of retinopathy beside the traditional fundus examination in diabetic patients.

FR-PO573

Prognostic Importance of Urea and Urea: Creatinine Ratio for Mortality as Compared to Creatinine Concentrations Alone in the General Population Ronan Cusack,[2] Austin G. Stack,[1,2,3] John P. Ferguson.[2] *[1]Nephrology, Univ Hospital Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland; [3]Health Research Inst, Univ of Limerick, Ireland.*

Background: High Creatinine (Cr) concentrations reflect poor kidney function and are associated with a higher risk of death. It is unclear whether other measures of kidney function such as blood urea nitrogen (BUN) concentration and BUN/creatinine ratio, are better predictors of mortality in the general population.

Methods: A cohort of 15,773 non-pregnant subjects age >20, representative of the U.S. population, were identified from the Third National Health and Nutrition Examination Survey (1988-1994). Vital status was obtained through linkage with the National Death Index through to 2006. Subjects were classified into categories of Cr, BUN and BUN/Creatinine Ratio (B/Cr). Weighted multivariable Cox regression models, compared hazard ratios [HR] and 95% CI for death among the decile groups and the prognostic capacity of differing models was compared using Akaike Information Criterion (AIC).

Results: In multivariable analysis, BUN was found to be the most important single predictor of mortality with Cr being second best. A strong interaction (P< 0.001) between BUN and Cr with mortality was identified and explored by fitting stratified models, as shown below.

			Creatinine (µmol/L)				
	< 70.7	**70.7-79.6**	**79.6-88.4**	**88.4-97.2**	**97.2-106.1**	**106.1-114.9**	**≥ 114.9**
Urea (mmol/L)							
< 2.86	1.55 (0.75-3.18)	1.00	0.60 (0.28-1.26)	0.51 (0.16-1.67)	0.21 (0.06-0.69)	0.20 (0.06-0.62)	0.09 (0.02-0.45)
2.86-7.5	1.04 (0.81-1.34)	1.00	0.99 (0.82-1.20)	1.04 (0.87-1.25)	1.04 (0.83-1.29)	0.97 (0.77-1.23)	1.28 (1.00-1.64)
> 7.5	0.84 (0.31-2.25)	1.00	1.78 (0.72-4.40)	1.13 (0.55-2.34)	1.49 (0.70-3.19)	1.98 (0.96-4.09)	2.31 (1.15-4.63)

Conclusions: Both BUN and Cr independently predict death in the general population. Among patients with malnourished states (Low BUN); higher SC were associated with lower mortality. In contrast, among patients with normal-high BUN concentrations, higher Cr was associated with elevated death risk. Risk Prediction models should take BUN levels into consideration when estimating future death risk.

FR-PO574

Serum Uric Acid and the Development of Chronic Kidney Disease in a General Japanese Population: The Hisayama Study Keita Takae,[1,2] Masaharu Nagata,[1,2] Kazuhiko Tsuruya,[2] Takanari Kitazono,[2,3] Yutaka Kiyohara,[1,3] Toshiharu Ninomiya.[2,3] *[1]Dept of Environmental Medicine, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [3]Center for Cohort Studies, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Growing evidence suggests that high serum uric acid (SUA) levels are causally related to an increased risk of kidney dysfunction. However, the association remains inconclusive in general Asian populations. Additionally, there are limited studies investigating the influence of SUA levels on the development of albuminuria.

Methods: A total of 2,059 community-dwelling Japanese subjects aged ≥40 years without chronic kidney disease (CKD) were followed for 5 years. CKD were defined as eGFR <60 mL/min/1.73m² or urine albumin/creatinine ratio (UACR) ³30 mg/g, The odds ratios (ORs) for the development of CKD and the rates of decline in eGFR were estimated according to quartile of SUA (≤4.0, 4.1-4.9, 5.0-5.8, and ≥5.9 mg/dL).

Results: During follow-up period, 396 subjects experienced CKD, of whom125 had eGFR <60 mL/min/1.73m² and 312 had UACR ³30 mg/g. The age- and sex-adjusted incidence rate of CKD increased significantly with higher SUA levels (p for trend <0.001). Compared with those with SUA of ≤4.0 mg/dL, the multivariable-adjusted ORs for the development of CKD were 1.21 (95% confidence intervals, 0.84-1.74), 1.47 (1.01-2.17), and 2.10 (1.37-3.23) in subjects with SUA of 4.1-4.9 mg/dL, 5.0-5.8 mg/dL, and ≥5.9 mg/dL, respectively. Likewise, there were positive associations of SUA levels with the adjusted risk of developing eGFR <60 mL/min/1.73m² (OR 1.00 [reference] in ≤4.0 mg/dL, 2.30 [1.10-4.82] in 4.1-4.9 mg/dL, 2.81 [1.34-5.88] in 5.0-5.8 mg/dL, and 3.73 [1.65-8.44], in ≥5.9 mg/dL) and UACR ³30 mg/g (1.00 [reference], 1.12 [0.76-1.65], 1.35 [0.90-2.03], and 1.81 [1.14-2.87], respectively). Additionally, higher SUA was significantly associated with a greater decline in eGFR (p for trend = 0.002).

Conclusions: Higher SUA level is a significant risk factor for the development of both kidney dysfunction and albuminuria in a general Japanese population.

FR-PO575

Do Protein-Energy Wasting Criteria Reflect Protein/Energy Wasting? Xiaorui Chen,[1] G. Wei,[1] Robert E. Boucher,[1] Dominique Ferranti,[3] Michel Chonchol,[1] Kalani L. Raphael,[1] Srini Beddhu.[1,2] *[1]U of Utah; [2]VA SLC; [3]UC Denver.*

Background: The term protein-energy wasting (PEW) implies a state of depleted protein and/ or energy stores. An International Society of Renal Nutrition and Metabolism (ISRNM) panel proposed objective criteria for the definition of PEW syndrome. However, the extent to which these variables used in PEW syndrome definition are indicative of low protein or energy stores is unknown. Muscle is the largest protein store and fat mass is the largest energy store in the body. Therefore, we examined the associations of these variables with lean body mass (LBM) and fat mass (FM) measured by DXA scans in 11,834 participants in the 1999-2004 National Health and Nutrition Examination Survey (NHANES).

Methods: Definitions of PEW variables are summarized in the table. The associations of each PEW variable with LBM and FM in the entire cohort and CKD (CKD-EPI eGFR < 60) sub-population were examined in linear regression models using svy suite in STATA 13.

Results: Mean age was 46.0 yrs, 50.3% were male, 9.5% were black. 6.7% had CKD. Unintentional weight loss and low levels of serum albumin, serum cholesterol, BMI and MAMC were associated with lower LBM and FM. On the other hand, low protein and energy intakes were associated with *higher* LBM and FM.

PEW variables	Lean body mass (kg)	Fat mass (kg)
	β (95% CI)	
Albumin<3.25 g/dl	-3.5 (-7.5, 0.4)	-3.6 (-7.2, -0.1)
Cholesterol<100 mg/dl	-2.5 (-6.8, 1.8)	-5.2 (-10.6, 0.1)
BMI<20 kg/m²	-9.7 (-10.3, -9.1)	-14.6 (-14.9,-14.2)
Unintentional wt loss> 10% over 1 yr	-2.2 (-3.3, -1.0)	-3.8 (-5.2, -2.4)
Body fat %<10%	NA	NA
Low MAMC*	-8.6 (-9.0, -8.3)	-8.4 (-8.9, -7.9)
Protein intake<0.6 g/kg/d	3.6 (3.0, 4.2)	6.4 (5.7, 7.0)
Energy intake<25 kcal/kg/day	4.3 (3.9, 4.7)	7.3 (6.9, 7.7)

* 10% or more lower than the 50th percentile of reference group

Results were similar in the CKD sub-population.

Conclusions: Serum chemistry, body weight and muscle mass PEW criteria appear to be indicative of both protein stores (as indicated by LBM) and energy stores (as indicated by FM). Dietary variables are not reflective of protein or energy wasting. A modified PEW syndrome definition without the dietary variables would be a better indicator of PEW syndrome.

Funding: NIDDK Support

FR-PO576

Low-Proteinuric CKD and Risk of ESRD in Nephrology Clinics: Emerging Role of Serum Phosphorus Luca De Nicola,[1] Michele Provenzano,[1] Paolo Chiodini,[2] Giuseppe Conte,[1] Roberto Minutolo.[1] *[1]Nephrology, Second Univ, Naples, Italy; [2]Med Stat, Second Univ, Naples, Italy.*

Background: In low-proteinuric (LP) CKD, factors other than proteinuria (Uprot) likely act as predictors of ESRD. However, comprehensive assessment of epidemiologic features of LP versus high-proteinuric (HP) patients is still lacking. This information is critical in renal clinics where LP patients are common.

Methods: We pooled three prospective cohorts that in 2000-2010 enrolled 2,488 CKD patients stage III-V under stable care from ≥6 months in 40 Italian renal clinics. Patients were followed for ESRD (chronic dialysis-transplant) up to 12/2014. Patients were classified in two groups, LP (56%) and HP (44%), by Uprot £0.5 and >0.5 g/24h, respectively.

Results: Besides lower Uprot (median, IQR: 0.15, 0.06-0.28 vs 1.20, 0.78-2.05 g/24h), LP differed from HP because male gender (55 vs 62%), diabetes (28 vs 35%) and use of anti-RAS (73 vs 78%) were less frequent. In LP, moreover, age (70±12 vs 65±14 y), GFR-EPI (35.2±13.3 vs 26.6±13.2 mL/min/1.73m^2) and Hb (12.7±1.7 vs 12.3±1.8 g/dL) were higher while systolic BP (137±18 vs 140±18 mmHg) was lower. Serum phosphorus (P) was lower in LP (3.68±0.73 vs 3.95±0.83 mg/dL, with P>4.5 mg/dL in 10 vs 20%) [P<0.001 for all comparisons]. History of cardiovascular disease (CVD), BMI and uric acid levels did not differ. Over a median follow-up of 38 months, ESRD occurred in 154 LP and 422 HP, (incidence rate 2.9 and 12.2/100 pts/y). At multivariable Cox analyses (HR, 95% CI), significant predictors of ESRD were male gender, younger age and lower eGFR in both LP and HP. Only in LP, however, higher P (1.28, 1.02-1.61) and lower BMI (0.96, 0.93-0.99) predicted renal risk while CVD (1.28, 1.03-1.60), Hb (0.90, 0.85-0.97) and anti-RAS (0.74, 0.60-0.91) had a prognostic role exclusively in HP. A negative interaction P*Uprot was detected in HP (beta= -0.046, P=0.004). Results were consistent across cohorts.

Conclusions: In renal clinics, LP patients are prevalent and characterized by nontrivial renal risk despite higher eGFR. Risk factors for ESRD are peculiar; in particular, results in LP and HP suggest that lower Uprot allows full expression of the negative role of P, the effect being evident for P levels mostly normal.

FR-PO577

Trends in CKD Awareness in the U.S. Population, 1999-2012, Overall and by KDIGO Risk Groups Yunnuo Zhu,[1] Tanushree Banerjee,[1] Delphine S. Tuot,[1] Jennifer L. Bragg-Gresham,[2] Mark Eberhardt,[3] Sharon Saydah,[3] Rajiv Saran,[2] Neil R. Powe.[1] *[1]UCSF; [2]UM; [3]CDC.*

Background: Despite medical knowledge of chronic kidney disease (CKD) as a risk factor of cardiovascular disease, hypertension, and progression to kidney failure, a majority of patients are not aware of their disease. Early identification and management of CKD can decrease its rate of progression.

Methods: We used cross-sectional National Health and Nutrition Examination Survey data (1999-2012) of non-pregnant adults aged ³20 years with CKD who had complete urinary albumin and creatinine data (N=8,480-10,296). CKD stages 1-4 were classified using KDIGO's prognosis of CKD risk levels based on GFR and albuminuria. The risk categories range from low to very high risk and predict the risk of CKD progression, ESRD, and mortality. eGFR was estimated using the MDRD equation. CKD awareness was defined by answering "yes" to the question "Have you ever been told that you had weak or failing kidneys?" amongst those with CKD. We used weighted, age-adjusted regression analyses via SAS SURVEYREG to analyze prevalence and trends.

Results: Overall prevalence of CKD awareness across all risk groups in 2009-2012 was 4.7% and had not significantly changed compared to 4.4% in1999-2004 or 4.7% in 2005-2008 (p trend=0.96). Awareness in the very high KDIGO risk group for progression was greatest and increased from 40.5% in 1999-2004 to 51.6% in 2009-2012 (p trend=0.007). The prevalence of self-report CKD awareness was 16.6% in the next highest risk group in 2009-2012 but did not exhibit a statistically significant trend (p trend=0.56). The moderately increased risk group showed a decrease in awareness from 6.3% in 1999-2004 to 4.1% in 2009-2012 that was not statistically significant (p trend=0.14). Awareness in the low-risk group was the lowest of all risk groups at 2.0% in 2009-2012 and showed no change over time (p trend=0.67).

Conclusions: Although overall awareness of CKD has not changed over time, awareness among those at highest risk for CKD progression has increased. Recent education efforts to increase awareness among providers and patients may be reaching those at greatest risk and acceleration might help mitigate CKD progression and associated comorbidities.

Funding: Other U.S. Government Support

FR-PO578

Intermittent Abnormal Kidney Function and Mortality in Community Dwelling Individuals Donal J. Sexton,[1] Scott Reule,[2] Robert N. Foley.[2] *[1]Medicine, HRB Clinical Research Facility, NUIGalway, Galway, Ireland; [2]Medicine, Univ of Minnesota, Minneapolis.*

Background: The health implications of persistently abnormal kidney function as measured by estimated glomerular filtration rate and spot urinary albumin excretion has been well characterized to date. However little data is available regarding the implications of intermittent abnormalities in these tests as defined by established thresholds.

Methods: We evaluated the frequency of intermittent abnormal kidney function and its association with all-cause mortality in the US general population using the National Health and Nutrition Examination Survey III, 1988-1994. Mortality linkage data were available through December 2006. Estimated glomerular filtration rate (eGFR) calculated using the CKD-EPI equation and urinary albumin-creatinine ratios (ACR) were measured twice, a mean of 17 days apart (N=1161).

Results: Proportions of abnormal tests included: for eGFR < 60ml/min/1.73m^2 either test 7.32 %, first test 5.94%, second test 5.68%, first test only 1.64%, second test only 1.38%, both tests 4.31%. Compared to participants with eGFR ≥ 60 ml/min/1.73m^2 on both testing occasions, adjusted hazard ratios were 1.8 (95%CI 1.3, 2.4) for intermittent and 1.7 (95%CI 1.1, 2.5) for persistent abnormal eGFR. Proportions with ACR ≥ 30 mg/g were as follows: either test 16.54%, first test 11.63%, second test 13.35%, first test only 3.19%, second test only 4.91%, both tests 8.44%. Compared to those with ACR < 30 mg/g on both occasions' mortality hazard ratios for intermittent abnormal function was 2.1 (95%CI 1.6, 2.7), and persistent abnormal 2.0 (95%CI 1.5, 2.8). Models were adjusted for age, sex, race, diabetes mellitus, cardiovascular disease (congestive heart failure, previous myocardial infarction or stroke), current smoking, self reported hypertension, systolic and diastolic blood pressure, total cholesterol and body mass index.

Conclusions: CKD as defined by established thresholds may be persistent or intermittent in community dwelling individuals. Participants with intermittently abnormal kidney function as defined by current thresholds were at similar mortality risk to those with persistently abnormal function on both occasions.

FR-PO579

Renal Outcome of APRT Deficiency Presenting in Childhood Hrafnhildur L. Runolfsdottir,[1] Runolfur Palsson,[1,2] Inger Maria Agustsdottir,[3] Olafur S. Indridason,[2] Vidar O. Edvardsson.[1,3] *[1]Faculty of Medicine, Univ of Iceland; [2]Div of Nephrology; [3]Children´s Medical Center, Landspitali – The National Univ Hospital of Iceland, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase (APRT) deficiency is an inherited disorder of purine metabolism that leads to nephrolithiasis and chronic kidney disease (CKD). Scarce data are available on APRT deficiency presenting in childhood.

Methods: All patients in the APRT Deficiency Registry of the Rare Kidney Stone Consortium who presented with clinical manifestations of the disorder and/or were diagnosed with the disease before age 18 years were included in the study. Presenting features, time to diagnosis and disease course were examined. Glomerular filtration rate (eGFR) was estimated with the modified Schwartz equation in children and the MDRD equation in adults. CKD was defined as eGFR <60 ml/min/1.73 m^2 and acute kidney injury (AKI) according to the KDIGO criteria. Data are presented as median (range).

Results: Nineteen children presented at the age of 1.6 (0.2-16.5) years. Presenting features included reddish-brown diaper spots in 11 patients (58%), kidney stones in 8 (42%), lower urinary tract symptoms in 8 (42%) and AKI in 2. The diagnosis was promptly made in 7 patients, while it was delayed in 12 (63%) patients for 15.2 (0.8-39.2) years. One patient, who did not receive drug treatment, developed ESRD at age 11 years. Twelve patients were placed on allopurinol at the age of 2.1 (0.6-16.5) years. During follow-up of 18.9 (1.7-31.5) years, 3 of these patients developed 4 kidney stone events and AKI occurred in 2 patients during episodes of volume depletion; none had developed CKD. Six patients did not begin pharmacotherapy until age 29.8 (20.5-42.4) years. At last follow-up, at 43.9 (32.5-56.9) years of age, 3 had experienced a total of 9 kidney stone events, 2 had suffered AKI, 3 had stage 3 CKD and one had progressed to ESRD at the age of 44 years.

Conclusions: A substantial proportion of patients with APRT deficiency present in childhood. The commonly observed delay in diagnosis and treatment may have grave consequences. APRT deficiency must be excluded in all children with kidney stones, renal dysfunction and reddish-brown diaper spots.

Funding: Other NIH Support - This study was supported by the Rare Kidney Stone Consortium (U54KD083908), a part of the National Center for Advancing Translational Sciences (NCATS) Rare Diseases Clinical Research Network (RDCRN). RDCRN is an initiative of the Office of Rare Diseases Research (ORDR). The Rare Kidney Stone Consortium is funded through collaboration between NCATS and National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK).

FR-PO580

Association of Chronic Kidney Disease with Increased Risk of Recurrence of Upper Urinary Tract Urothelium Cancer – A Population-Based Study

Shang-Jyh Hwang,[1,3] Ming-Yen Lin,[1] Huei-Lan Lee,[1] Wei-Ming Li,[1] Chun-Nung Huang,[1] Wen-Jeng Wu,[1] Li-Tzong Chen,[3] Sheng-wen Niu.[1] *[1]Medical Univ Hospital, Kaohsiung, Taiwan; [2]National Health Research Insts, Miaoli, Taiwan.*

Background: Taiwan has significantly high incidence of upper urinary tract urothelial cancer (UTUC) and end-stage renal disease (ESRD). UTUC coexisted with chronic kidney disease (CKD) may deteriorate cancer progression and increase mortality risk. The aim of study was to explore the association of CKD with the risk of UTUC recurrence.

Methods: We conducted a population-based cohort study through Taiwan National Health Insurance Research Dataset. Incident UTUC patient was extracted from Taiwan Cancer Registry Dataset and linked to claim data. Status of CKD including non-dialysis CKD, dialysis ESRD, and renal transplant were identified before the index date of UTUC. Recurrence was defined as either new tumor lesion in bladder, or at the other site of urinary tract, or occurrence of distant metastasis within 3 months after first surgery. Differences of characteristics between CKD and non-CKD group was described as mean ± standard deviation or percentage and tested by independent t test and chi-square test. Competing risk approach was used for estimating cause-specific hazard ratio (CSHR) and 95% confidence interval (CI).

Results: Totally, 4,002 UTUC patients from 2001 to 2005 were included and traced until disease recurrence or end of 5 years after the index date of UTUC. Near half patients accompanied with various stages and status of CKD at index date. UTUC patients with CKD were younger, more female, and had more co-morbidities than patients without CKD. After adjusting factors of age, tumor grade, and co-morbidities, CKD significantly increased risk of UTUC recurrence in female (CSHR: 1.72, 95%CI: 1.13-2.61, p=0.01), but not in male (CSHR: 0.91, 95%CI: 0.44-1.86, p=0.79).

Conclusions: CKD increases risk of recurrence in female UTUC patient and is an important prognostic indicator.(This study was granted by the Ministry of Science and Technology(NSC 102-2314-B-037-012-MY3) and by the Ministry of Health and Welfare (MOHW103-TD-B-111-05, MOHW104-TDU-B-212-124-003, budget from health and welfare surcharge of tobacco product).)

Single Centre Experience of Late Referral and Achievement of Useable Dialysis Access Over a 9-Year Period

Mohamed Salah Eldin Khogali. *Renal Dept, Dorset County Hospital, Dorchester, Dorset, United Kingdom; Renal Dept, Dorset County Hospital, Dorchester, Dorset, United Kingdom.*

Background: We describe a single centre, retrospective analysis of late (≤ 90 days) referral for dialysis over a 9 year period from April 2003 till March 2012. Factors that contributed to late referral and success in creating permanent dialysis access were determined.

Methods: Data on adult patients referred ≤ 90 days from dialysis were collected including patient demographics, source of referral, mortality, reason for late referral, creation of permanent dialysis access and use of permanent dialysis access at first dialysis.

Results: One hundred and twenty-seven patients were referred in ≤ 90 days over the 9 year period. Ninety-nine (78%) patients were referred within 30 days prior to dialysis and 28 (22%) patients within 30 – 90 days. Their median age was 63 years and 80 (63%) patients were male. Twenty- five (20%) patients were diabetic. Forty (33%) patients died within the first year after referral, 25 (21%) patients within the first 6 months and 15 (12%) patients between 6 months and 1 year.(figure1) Sixty-five patients (51 %) presented late due to acute renal failure (myeloma 24, vasculitis 14, irreversible acute kidney injury 10, renal cell carcinoma 5, glomerulonephritis 3 and others 9). Twenty-nine patients (23%) referred by physicians and surgeons, and 24 patients (19%) referred by GPs were late referrals of patients with known chronic renal failure. Nine patients (7%) presented late due to lack of understanding of their disease, denial, and fear of the unknown. One hundred and ten patients had permanent dialysis access created and 17 patients no permanent access procedures. The average time to create permanent dialysis access was 44 days post-dialysis commencement. Six permanent haemodialysis accesses were created pre-dialysis, 56 post-dialysis; 19 peritoneal dialysis accesses were created pre- dialysis, 29 post-dialysis.

Conclusions: Overall the number of patients presenting late for dialysis has decreased. Late referral has a poor 1 year survival and most patients require haemodialysis long-term. Only a minority of patients referred late have permanent dialysis access created and used at their first dialysis.

FR-PO582

Abnormal Global Glomerular Sclerosis Rate in Remnant Kidney of Ipsilateral Nephroureterectomy Is Associated with Higher Risk of End-Stage Renal Disease within Five Years in Patients of Upper Urinary Tract Urothelial Carcinoma

Sheng-wen Niu,[1] Peir-In Liang,[1] Shih-Mong Yeh,[1] Ming-Yen Lin,[1] Shang-Jyh Hwang,[1,2] Wen-Jeng Wu.[1] *[1]Kaohsiung Medical Univ, Taiwan; [2]National Health Research Insts.*

Background: Aristolochic acid in Chinese herbs induce renal tubuleinterstitial disease and increase the risk of upper urinary tract urothelial carcinoma(UTUC). However, we are still not sure if UTUC itself has impact on renal outcome. We studied the pathological changes of remnant kidney tissue from UTUC patients post ipsilateral nephroureterectomy to investigate the correlation between renal histopathology and outcome of end-stage renal disease.

Methods: This cohort study included 132 cases of non-dialysis UTUC patients post ipsilateral nephroureterectomy from 2002 to 2010. We collected clinical and laboratory data before surgery, tumor size, whether into dialysis after surgery, and followed up to dialysis or to December 31, 2014. Renal histopathology was read by 3 specialists: nephrologists or pathologist. We used logistic regression for studying tubuleinterstitial fibrosis score and global glomerular sclerosis (GGS) rates and Cox regression to investigate factors associated with renal survival.

Results: There was no significant factor associated with tubuleinterstitial fibrosis, but advanced CKD was significantly related to GGS rate adjusted with age and gender [OR(95%CI): 4.8(1.4-16.9), p=0.014]. Kaplan-Meier survival curve showed five-year renal survival rate was 86.3%. Factors affect five-year renal survival were hypertension [HR(95%CI): 4.0(1.1-15.2), p=0.043] and GGS rate [HR(95%CI): 17.4(2.4-124.1), p=0.004].

Conclusions: Our findings demonstrated that UTUC patients with hypertension before surgery or abnormal GGS rate in remnant kidney have higher risk of entering dialysis within five years post ipsilateral nephroureterectomy.(This study was granted by the Ministry of Science and Technology (NSC 102-2314-B-037-012-MY3) and by the Ministry of Health and Welfare (MOHW103-TD-B-111-05, MOHW104-TDU-B-212-124-003, budget from health and welfare surcharge of tobacco product)).

FR-PO583

Renal Outcomes following Transjugular Intrahepatic Portosystemic Shunt Placement for Refractory Ascites: A Large Case Series

Andrew S. Allegretti,[1] Guillermo Ortiz,[1] Jie Cui,[1] Ishir Bhan,[1] Raymond T. Chung,[2] Zubin Irani.[3] *[1]Div of Nephrology, MGH, Boston, MA; [2]Div of Hepatology, MGH, Boston, MA; [3]Dept of Radiology, MGH, Boston, MA.*

Background: Patients with cirrhosis and refractory ascites have decreased effective circulating volume that contributes to impaired renal perfusion and diminished estimated glomerular filtration rate (GFR). Reversing these hemodynamic alterations via transjugular intrahepatic portosystemic shunt (TIPS) procedure may improve GFR.

Methods: Multicenter, retrospective review of patients who underwent first-time TIPS placement for refractory ascites from 1995 to 2014. Patients were analyzed at 90 days prior to TIPS, immediately pre- and post-TIPS, and 90 days after TIPS. Change in renal function 90 days after TIPS was analyzed by GFR tertiles (T1: > 60 mL/min, T2: 37-60 mL/min, T3: <37 mL/min) at the time of TIPS procedure.

Results: 153 TIPS cases were analyzed. Mean GFR was 62 (95% CI 58, 69) mL/min at 90 days prior to TIPS, 53 (48, 58) mL/min immediately pre-TIPS, 64 (59, 69) mL/min post-TIPS, and 74 (CI 68, 80) mL/min 90 days after TIPS.

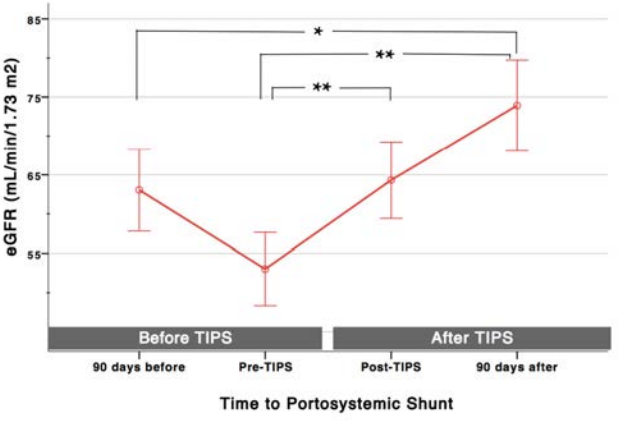

Figure. Longitudinal measures of mean eGFR around time of TIPS procedure. *p<0.001, **p<0.0001

GFR improved by 16 (11, 21) mL/min from pre-TIPS to 90 days after TIPS (p <0.0001). Comparison of Tertiles 1, 2, and 3 showed respectively: GFR increased by T1: 6 (-1, 14), T2: 22 (15, 30), and T3: 22 (12, 33) mL/min (p = 0.006); 90-day mortality was T1: 20%, T2: 17%, and T3: 49% (p = 0.0007); encephalopathy rate at 90 days was T1: 21%, T2: 42%, and T3: 65% (p = 0.0005).

Conclusions: There was a significant improvement in GFR from pre-TIPS to 90 days after TIPS. Those with the lowest GFRs at the time of TIPS had greater improvement in renal function but also had higher 90-day mortality and encephalopathy rates post-TIPS.

The Epidemic of Chronic Kidney Disease in Rural and Remote Canadian First Nations: Results from Manitoba's FINISHED Screening Program

Paul Komenda,[1,3] Barry Ad Lavallee,[1,2] Thomas W. Ferguson,[3] Navdeep Tangri,[1,3] Allison Dart,[1] Bing Hu,[4] Audrey Gordon,[4] Caroline D. Chartrand,[2] Lorraine L. Mcleod,[2] Claudio Rigatto.[1,3] *[1]Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [2]Diabetes Integration Project, Winnipeg, MB, Canada; [3]Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; [4]Seven Oaks General Hospital Research Centre, Winnipeg, MB, Canada.*

Background: Chronic Kidney Disease (CKD) is a global epidemic affecting 10-15% of the general population. Canadian First Nations children and young adults are known to suffer from a high rate of proximate risk factors for CKD, in particular elevated rates of diabetes. The rates of CKD are not well defined in this population. We used data from The First Nations Community Based Screening to Improve Kidney Health and Prevent Dialysis (FINISHED) project, a 3-year initiative completed in 2015 that accomplished community wide screening in 11 rural and remote First Nations communities in Manitoba, Canada.

Methods: Detailed methods of the FINISHED study have been previously published (Lavallee et al. CJKHD, 2015). An interdisciplinary team screened for CKD in adults and children aged 10 + using both urine albumin-to-creatinine ratio (ACR) and eGFR in 11 communities across 2 tribal councils. We present here the data on demographic variables, risk factors for CKD, and the prevalence and severity of CKD in the adult (age 18+) screening cohort.

Results: 1346 adults were screened. 26.7% of those screened had CKD defined as elevated urine ACR (micro- or macroalbuminuria) or eGFR < 60 ml/min/1.73m^2. Road access communities had a lower prevalence of CKD (18.4%) than remote air access communities (36.0%). Macroalbuminuria (urine ACR > 300 mg/g) was present in 5% of those screened (2.8% in road access and 7.5% in air access communities).

Conclusions: Rural and remote Canadian First Nations suffer up to a 3-fold higher prevalence of CKD than the general population and a nearly 5-fold higher prevalence of macroalbuminuria. This prevalence is comparable to high-risk populations such as those with diabetes and/or hypertension. Given these risks, screening and treatment interventions may be cost-effective, as they have been shown to be in other high-risk populations.

FR-PO585

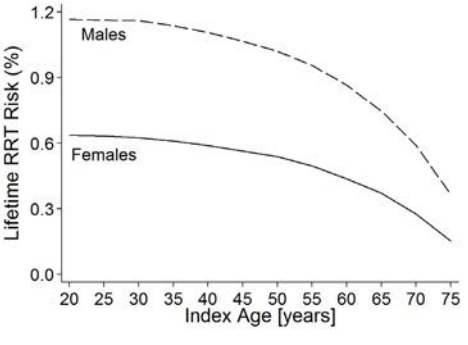
Age and Gender Specific Lifetime Risk of Renal Replacement Therapy

Jan A.J.G. van den Brand,[1] Maria Pippias,[2] Vianda S. Stel,[2] Jack F. Wetzels,[2] Kitty J. Jager.[2] *[1]Dept of Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]ERA-EDTA Registry, Academic Medical Centre Univ of Amsterdam, Amsterdam, Netherlands.*

Background: Kidney transplantation is the preferred treatment of end stage renal disease (ESRD). Graft and patient survival are highest after transplantation with a graft from a living donor. However, persons who donate a kidney are themselves at risk of ESRD. Personalized risk prediction requires age and gender specific risk estimates. Here, we report lifetime risk of renal replacement therapy (RRT) for ESRD by age and gender across Europe.

Methods: We defined ESRD as chronic RRT and age 80 as the lifetime horizon. Death was considered a competing event. We obtained RRT incidence rates by age and gender from the ERA-EDTA Registry. Mortality rates were calculated from census data provided by EuroStat. We used these rates to estimate cumulative incidence of RRT by age and gender for countries providing individual patient data to the ERA-EDTA Registry. We pooled lifetime RRT risks using inverse variance weighted means.

Results: At index age 20, lifetime RRT risk for females ranged between 0.40% and 0.87% across countries, and for males between 0.77% and 1.59%. At age 60, lifetime RRT risk ranged between 0.26% and 0.68% for females and 0.56% and 1.32% for males. Pooled lifetime RRT risk in Europe was 0.62%, 0.58% and 0.43% in 20, 40 and 60 year old females. In males the respective risks were 1.16%, 1.10% and 0.87% for index ages 20, 40 and 60. The figure shows pooled lifetime RRT risk estimates by index age.



Conclusions: Lifetime RRT risk differs across Europe. Women are at lower risk compared to men. These data offer a basis to provide personalized prediction of lifetime ESRD risk when evaluating a potential kidney donor. The estimates presented here are population averages. We expect that lifetime risk is lower in persons with normal eGFR and no albuminuria.

FR-PO586

Characterizing Risk Among Type 2 Diabetics with Preserved EGFR and Abnormal Urine Albumin Excretion

Robert M. Perkins,[1] Alex R. Chang,[2] H. Lester Kirchner.[2] *[1]Bayer HealthCare, Whippany, NJ; [2]Geisinger Medical Center, Danville, PA.*

Background: Updated CKD risk stratification guidelines promote earlier identification of higher-risk patients. Two conditions are required to improve outcomes among such patients: robust risk characterization, and the presence of modifiable factors.

Methods: We investigated a retrospective cohort of all adult type 2 diabetic patients receiving care in an integrated health care system in central Pennsylvania during the period 1/1/2004-12/31/2014. Patients were risk stratified using the 2002 NKF and, separately, the 2012 KDIGO CKD classification systems. We compared the predictive performance of the two classification systems for death and ESRD using Akaike Information Criterion (AIC) obtained from multivariate, Cox proportional hazards models. Using only the KDIGO 2012 classification system, we then investigated patients categorized as stage G1 or G2 (with 'high' or 'very high' albuminuria) for the presence of modifiable risk factors.

Results: 17,385 type 2 diabetics comprised the study population (median follow-up 6.8 years). Median age and eGFR were 60 years and 95 ml/min/1.73m^2, respectively. 53% were male, 44% had a smoking history, and 16% and 5% had a history of coronary disease and CHF, respectively. Although both classification systems discriminated risk reasonably well, the KDIGO 2012 system—incorporating uACR—had lower AIC scores and was more likely to minimize information loss. Across all risk factors examined, less than half the population was receiving recommended care.

Table 1. Multivariate Cox proportional hazard models for ESRD and Death, by CKD risk stratification system

Risk Classification System	Adjusted HR (95% CI)
ESRD[1]	
NKF 2002 (eGFR < 60 vs ≥ 60)	11.4 (9.2—14.0)
KDIGO 2012 (moderate vs. low risk)	2.2 (1.6—2.9)
KDIGO 2012 (high vs low risk)	10.1 (7.6—13.3)
Death[2]	
NKF 2002 (eGFR < 60 vs ≥ 60)	1.6 (1.5—1.8)
KDIGO 2012 (moderate vs. low risk)	1.5 (1.4—1.6)
KDIGO 2012 (high vs low risk)	2.3 (2.1-2.6)

[1]Adjusted for age, gender, hospital admission year prior to index, PVD, CHF, ACEI/ARB use, statin use, blood pressure, LDL, serum albumin, HbA1C
[2]Adjusted for age, gender, smoking status, hospital admission year prior to index, PVD, CHF, ASCAD, Stroke, statin use, blood pressure, BMI, LDL, serum albumin, HbA1C

Table 2. Modifiable risk factors among type 2 diabetics with eGFR ≥ 60 ml/min/1.73m^2 and 'high' or 'very high albuminuria'

KDIGO 2012 Risk Category	NSAID Prescription	Blood Pressure ≤ 130/80	LDL ordered (index +/- 12 months)	Statin Prescription	ACEI/ARB prescription
G1-A2	13%	39%	20%	6%	31%
G1-A3	9%	35%	15%	5%	35%
G2-A2	12%	37%	34%	8%	39%
G2-A3	9%	26%	23%	6%	41%

Conclusions: This investigation confirms the feasibility of early risk characterization among patients with preserved eGFR and abnormal urinary albumin excretion. Care gaps are highly prevalent among these individuals and may serve as targets to improve long term outcomes.

FR-PO587

Detecting Bowel Cancer in Chronic Kidney Disease (CKD): The Detect Study

Germaine Wong. *Univ of Sydney, Australia.*

Background: CKD confers a 20% higher risk of colorectal cancer (CRC) than the general population, and has a very poor prognosis, with less than 50% of kidney transplant recipients surviving one year after diagnosis. The benefits and harms of screening for advanced colorectal neoplasms in CKD are unknown. We aim to determine the prevalence and spectrum of advanced colorectal neoplasms in CKD, and to evaluate the test performance characteristics of immunochemical faecal occult blood testing (iFOBT) for screening advanced colorectal neoplasms in CKD.

Methods: Participants with CKD stages III-V, on dialysis and with a kidney transplant, aged between 35 and 74 years were recruited from 10 centres in Spain, Canada, Australia and New Zealand. All received two screening iFOBTs, and those with at least one or more positive screens underwent colonoscopy, with test negatives verified by clinical follow up and data linkage.

Results: Of the1602 patients recruited to the study, [CKD stages III-V: n= 734 (45.8%); dialysis: n=392 (24.7%) and transplant n=476 (29.7%)], 345 (21.5%) had one or more positive screens. The prevalence of advanced colorectal neoplasms (7 colorectal cancers and 101 advanced colorectal adenomas) among those with CKD stages III-V, on dialysis and with kidney transplants was 5.7% (95%CI: 4.3%-7.6%), 7.9% (95%Cl: 5.6%-11.0%) and 5.9% (4.1%-8.4%) (p=0.10), respectively. The majority of the polyps were located in the sigmoid and transverse colon (n=63, 58%). The risk of serious complications including peritonitis and perforation was minimal (less than 1%). Overall, the positive predictive value (PPV) of iFOBT was 35.4% (95%CI: 29.9% - 41.3%).

Conclusions: Overall, the screening program appears acceptable to patients, appears safe, has reasonable predictive values and has detected a higher prevalence of advanced CRC neoplasms than in the general population.

FR-PO588

Subclinical Pulmonary Congestion Is Pervasive in Nephrotic Syndrome

Francesca Mallamaci,[1,2] Francesco Marino,[2] Carmela Martorano,[2] Rocco Tripepi,[1] Marianna Bellantoni,[1] Giovanni Tripepi,[1] Carmine Zoccali.[1] *[1]National Research Council of Italy, Inst of Clinical Physiology, Reggio Cal Unit, CNR-IFC, Reggio Calabria, Italy; [2]Nephrology, Transplantation and Hypertension Unit United Hospitals, Reggio Calabria, Italy.*

Background: In patients with Nephrotic Syndrome (NS) the lung is considered as an organ protected from the risk of edema. However information on objectively measured lung water in NS patients is lacking.

Methods: We measured lung water with an ultrasound technique (US) and with standard transthoracic impedance in an incident series of 42 asymptomatic patients with active NS. Eleven of these patients were re-studied during NS remission. Twenty-one healthy subjects formed the control group. US lung studies were performed after 5 and 60 minutes of supine resting and after 5 minutes of standing. Transthoracic impedance was measured after 30 min of supine resting only.

Results: In patients with active NS the median number of US-B lines (a metric of lung water) after 5 min in supine position was markedly higher [12; Interquartile range :7-25; p<0.001] than in healthy subjects [4; 2-9]. The difference between patients [16, 11-35] and controls [4; 2-9] amplified (p<0.001) after 60 min of supine resting and attenuated after 5 min of standing [9; 7-25 vs 4; 3-5, p=0.001]. After NS remission, the number of US B lines reduced to 5 (4-18) at 5 min and to 6 (5-22) at 60 min (P<0.001) approaching the normal range. Lung congestion in patients with active disease was fully confirmed by transthoracic impedance measurements (p<0.001 vs healthy controls).

Conclusions: Asymptomatic pulmonary congestion is pervasive in patients with NS. A clinical trial is needed to assess the usefulness of the application of this technique for the management of patients with NS.

FR-PO589

The Incidence of Malignancies prior to the Diagnosis of ANCA-Associated Vasculitis (AAV) Is Not Increased in Comparison to the Incidence in the General Population

Emma Elisabeth Van Daalen,[1] Chinar Rahmattulla,[1] Ron Wolterbeek,[2] Jan A. Bruijn,[1] Ingeborg M. Bajema.[1] *[1]Pathology, Leiden Univ Medical Center, Leiden, Netherlands; [2]Medical Statistics and Bioinformatics, Leiden Univ Medical Center, Leiden, Netherlands.*

Background: Several studies have found an increased malignancy risk before the diagnosis of AAV, especially in granulomatosis with polyangiitis (GPA), whereas data on microscopic polyangiitis (MPA) are scarce. It has been hypothesized that malignancies and AAV have common pathways in their pathogenesis (Ann Rheum Dis 2004, Rheumatology 2009). We studied the malignancy risks in patients before their AAV diagnosis to further elucidate this hypothesis.

Methods: We retrospectively retrieved data on 138 patients with biopsy-proven AAV diagnosed in the Netherlands. Malignancies prior to AAV diagnosis were identified using the Dutch National Pathology Database. The malignancy incidence was compared to the incidence in the general population, as reported by the Netherlands Cancer Registry. The Standardized Incidence Ratios (SIRs) were calculated, matching for gender, age and calendar time period. Separate analyses were performed for GPA and MPA.

Results: Twelve patients were diagnosed with cancer before the AAV diagnosis (mean follow-up: 11.8 years). Overall malignancy risk was not increased (SIR: 0.92, 95%CI: 0.48-1.61). Malignancy risks were also not increased for malignancies of the skin, bladder, kidney, lung, stomach, rectum and uterus (SIRs ranging from 1.71 to 4.77, not significantly increased). There was no difference in malignancy risk between GPA (SIR: 1.23, 95%CI: 0.49-2.53) and MPA (SIR: 0.98, 95%CI: 0.27-2.50) patients (relative risk: 1.26, 95%CI: 0.32-5.86).

Conclusions: We did not find an increased incidence of malignancies prior to AAV diagnosis compared to the general population. This is in contrast with previous studies, in which GPA was associated with preceding renal cell carcinoma, bladder cancer and non-melanoma skin cancer. Most other studies have not included microscopic polyangiitis patients, for which malignancy risk was not increased in our study. Our findings do not support the hypothesis that malignancies and AAV have a shared pathogenic pathway.

FR-PO590

Gastrointestinal Symptoms and Hypoalbuminemia in Chronic Kidney Disease Patients

Xuehan Zhang,[1,2] Nisha Bansal,[3] Alan S. Go,[4] Chi-yuan Hsu.[2,4] *[1]Peking Union Medical College Hospital; [2]Univ of California-San Francisco; [3]Univ of Washington; [4]Kaiser Permanente Northern California.*

Background: Hypoalbuminemia is an important risk factor for adverse outcomes in patients with CKD. Little is known about the relationship between gastrointestinal (GI) symptoms and serum albumin level in CKD.

Methods: This is a cross-sectional study of participants (N=3599) in the Chronic Renal Insufficiency Cohort (CRIC) study which collected information regarding potential uremic symptoms. For each of the 4 following symptoms: "bad taste in mouth," "loss of appetite," "nausea," "vomiting," we created a severity score by multiplying the number of symptomatic days in the past month by a severity scale of 1 to 3 (mild, moderate and severe). We then summed up the individual severity scores for an overall "GI symptom score." Dietary protein intake was measured via 24-hour urine. The main outcome was serum albumin level.

Results: Mean eGFR was 42.9±13.4ml/min/1.73m^2, and serum albumin level was 3.95±0.46 g/dL. 1702 subjects had one or more symptoms. Patients with lower eGFR were more likely to have GI symptoms.

	Odds Ratio (95% CI)			
Symptom	eGFR≥60ml/min/1.73m^2 (n = 370)	eGFR 45-60ml/min/1.73m^2 (n = 1166)	eGFR 30-45ml/min/1.73m^2 (n = 1375)	eGFR<30ml/min/1.73m^2 (n = 688)
A bad taste in your mouth?	1.0 (reference)	0.99 (0.75-1.32) P=0.9	1.22 (0.92-1.62) P=0.2	1.34 (0.99-1.82) P=0.06
Loss of appetite?	1.0 (reference)	1.21 (0.88-1.68) P=0.2	1.83 (1.34-2.52) P<0.001	2.01 (1.43-2.82) P<0.001
Nausea or being sick to your stomach?	1.0 (reference)	0.95 (0.72-1.25) P=0.7	1.24 (0.95-1.63) P=0.1	1.32 (0.98-1.78) P=0.06
Vomiting?	1.0 (reference)	1.08 (0.70-1.67) P=0.7	1.67 (1.11-2.54) P=0.02	1.76 (1.13-2.75) P=0.01

Compare with those without symptoms, CKD patients with progressively higher tertiles of GI symptom score were more likely to have lower serum albumin levels (-0.07, -0.09 and -0.13 g/dL, respectively)(all p<0.01). Patients with more GI symptom also had lower dietary protein intake (r=-0.141, P<0.01).

Conclusions: Increased prevalence of GI symptoms become apparent among CKD patients at relatively high eGFR levels (45 ml/min/1.73m^2). These symptoms correlated with important nutritional parameters.

FR-PO591

Obstructive Lung Function in CKD: NHANES 2007-2012

Sankar D. Navaneethan,[1] Susana Arrigain,[1] Mahboob Rahman,[1] Jesse D. Schold.[2] *[1]Cleveland Clinic; [2]CWRU.*

Background: Lung diseases are one of the leading causes of death in the general population. We aimed to study the prevalence of obstructive lung function in those with CKD. In addition, factors associated with obstructive lung function were examined.

Methods: Participants aged 20-79 years from the National Health and Nutrition Examination Survey (NHANES) 2007-2012 who underwent spirometry testing using similar protocols were included in this analysis. Global Initiative for Chronic Obstructive Lung Disease classification of COPD (FEV1/FVC <0.7) based on post-bronchodilator spirometric results was used to establish the prevalence of obstructive lung function with weights adjusted for non-response to spirometry. CKD was defined as presence of eGFR <60 ml/min/1.73 m^2 and/or UACR >30 mg/g. Factors associated with obstructive lung function were identified using logistic regression model for the entire cohort, CKD and non-CKD groups separately (using baseline spirometry).

Results: Out of 11,995 participants (CKD=1563; Non-CKD=10,432) who completed the baseline spirometry testing, 1,986 participants were eligible for but only 1049 complete post-bronchodilator spirometry. Prevalence of obstructive lung function using baseline spirometry data were 25% in CKD and 13% in non-CKD and GOLD criteria were 17% in CKD and 8% in non-CKD. Each 5 ml/min lower eGFR and proteinuria were associated with higher odds of having obstructive lung function in the entire cohort.

Table. Factors associated with obstructive lung function in the study cohort

Variable	Multivariable adjusted OR[a] (95% CI) for obstructive lung function N=10,876
Age per 1 yr increase	1.06(1.06,1.07)
Gender (Female vs. Male)	0.53(0.44,0.64)
Race	
White	Ref
Black	0.64(0.54,0.76)
Mexican American	0.37(0.31,0.45)
Other Hispanic	0.42(0.31,0.57)
Other race	0.88(0.55,1.41)
Smoking status	
Former	2.17(1.77,2.67)
Current	4.83(3.94,5.91)
Never	Ref
BMI, kg/m^2 (per 1 unit increase)	0.96(0.95,0.98)
Diabetes	0.94(0.73,1.21)
Hypertension	1.07(0.92,1.24)
Self-reported COPD	2.49(1.92,3.24)
EGFR (each 5 ml/min decline)	1.03(1.01,1.05)
Proteinuria (yes/no)	1.31(1.02,1.68)

a-model adjusted for demographics, smoking, comorbidities and kidney function

Old age, white race, smoking and self-reported COPD were associated with obstructive lung function in both CKD and non-CKD groups.

Conclusions: In this representative cohort of US population, prevalence of obstructive lung function is higher in those CKD. Lower eGFR and proteinuria are associated with obstructive lung function. Further studies examining the impact of lung diseases in CKD are warranted.

FR-PO592

Association of Serum Osteoprotegerin with Bone Loss in Chronic Kidney Disease: From the KNOW-CKD Study Chang Seong Kim,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Soo Wan Kim.[1] *[1]Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Republic of Korea; [2]Dept of Internal Medicine, Seoul National Univ, Seoul, Republic of Korea.*

Background: Osteoprotegrin (OPG), a potent inhibitor of oesteoclast activation, decreases bone resorption and has protective effects on bone mineral density (BMD). This study examined the association between serum OPG and bone loss in patients with chronic kidney disease (CKD), a condition associated with increased risk of bone fracture and mineral and bone disorder.

Methods: BMD at the lumbar spine, total hip and femur neck was assessed by dual energy X-ray absorptiometry; and serum OPG was measured at baseline in 1,423 CKD patients in the prospective KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease. Osteoporosis was defined to T score ≤ –2.5 in patients aged over 50.

Results: Increasing quartiles of serum OPG were significantly associated with lower BMD (lumbar spine, total hip and femur neck) compared with the lowest quartile of serum OPG. Multivariable linear regression model indicated that serum OPG was independently associated with decreased lumbar spine and total hip BMD (B, –0.489; 95% confidence interval [CI], –0.883,–0.095; P = 0.015, B, –0.349; 95% CI, –0.672,–0.027; P = 0.027, respectively); but femur neck BMD was not associated with serum OPG in women. No independent association was found between serum OPG and BMD in men after adjustments. In multivariable logistic regression analysis, serum OPG was associated with increased risk of osteoporosis in women, but was not in man (odds ratio [OR], 4.01; 95% CI, 1.27–12.67, P = 0.018; OR, 0.31; 95% CI, 0.06–1.52, P = 0.311, respectively).

Conclusions: Serum OPG was independently associated with lumbar spine and total hip BMD and increased risk of osteoporosis in female CKD patients. However, these associations were not found in male CKD patients.

FR-PO593

Growth in Children with Chronic Kidney Disease: A Report from the KNOW-Ped CKD (Korean Cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease) Eujin Park,[1] Yo Han Ahn,[1] Kyoung Hee Han,[2] Seong heon Kim,[3] Joo Hoon Lee,[4] Young seo Park,[4] Hee Gyung Kang,[1] Hae Il Cheong,[1] Curie Ahn,[5] IL-Soo Ha.[1] *[1]Dept of Pediatrics, Seoul National Univ Children's Hospital, Seoul, Korea; [2]Dept of Pediatrics, Jeju National Univ School of Medicine, Jeju, Korea; [3]Dept of Pediatrics, Pusan National Univ Children's Hospital, Yangsan, Korea; [4]Dept of Pediatrics, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Korea; [5]Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.*

Background: Growth impairment is common in children with chronic kidney disease (CKD) with profound and lifelong psychosocial impact. We investigated the characteristics of growth in Korean children with CKD.

Methods: Clinical characteristics along with anthropometric measurements were examined in subjects of KNOW-Ped CKD, Korean Cohort Study for Outcome in Patients With Pediatric Chronic Kidney Disease. Findings of 322 children (M:F 218:104), who were enrolled to the study from July 2010 to December 2013 in seven major pediatric nephrology centers of Korea, were analyzed to investigate the characteristics of growth in Korean pediatric CKD.

Results: Mean height- and weight- z scores of Korean pediatric CKD patients were -0.88±1.43 and -0.91±1.65. Mean BMI- z score was -0.36±1.25. Height defect was observed from early stage of CKD with mean height z-score 0.42 in CKD stage I. Short stature (z score < - 1.88, 20% of the subjects) and underweight (z score < - 1.65, 28% of the subjects) were associated with female sex, age younger than 2-year-old at enrollment, co-morbidity, and advanced CKD stage. Low BMI was associated with high blood pressure, co-morbidity and younger age. The final height-z score was -0.86±1.19, which is shorter than predicted adult height-z score (-0.33±0.7) calculated from their parental height.

Conclusions: Growth failure is one of the most important complications in pediatric CKD patient. More profound height, weight and BMI impairment were associated with younger age and co-morbidity. Children with these findings need close attention on their growth and may require earlier intervention to avoid severe growth impairment.

FR-PO594

Risk of Early Preterm Delivery in Pregnant CKD Patients – A Model for Counseling – The TOCOS Cohort (Torino Cagliari Observational Study) Giorgina B. Piccoli,[1] Rossella Attini,[2] Gianfranca Cabiddu,[3] Antonello Pani,[3] Tullia Todros.[2] *[1]ss Nefrologia Dept of Clinical and Biological Sciences, Univ of Torino, Italy; [2]Dept of Surgery, Univ of Torino, Italy; [3]Nephrology, Brotzu Hospital, Cagliari, Italy.*

Background: Chronic kidney disease (CKD), whose prevalence almost equals preeclampsia in pregnancy, increases the risks of adverse pregnancy outcomes; the degree is only partially known.

Methods: Objective: Development and internal validation of a prediction model to quantify the risks of early preterm delivery (<34 gestational weeks) selected as most relevant pregnancy outcome, in pregnant women with CKD. We developed the model in CKD women. A homogeneously followed-up, low-risk pregnant population served as controls. Setting: The two largest Italian Outpatient Units dedicated to the multidisciplinary follow-up of CKD in pregnancy. Patients: Pregnant women with CKD: 503 live-born singletons in CKD; 835 low-risk controls (2000-2013). Measurements: Outcome: early pre-term delivery. The candidate variables were readily measurable, available, inexpensive (hypertension, proteinuria, kidney disease and function). Bootstrapping was used for internal validation.

Results: Early preterm delivery was more frequent in CKD (12.5%) versus controls (1%) ($p<0.0001$). The most parsimonious model (Likelihood ratio test $p<0.0001$; McFadden's pseudo R^2=0.2290) summarized various combinations of CKD stages, hypertension and proteinuria and defined a scale of risk. First step included CKD stage1, normotension and proteinuria<1g/24h (OR:2.8); second step included CKD stages 2-5 without hypertension and proteinuria, and CKD stage1 with either hypertension or proteinuria (OR:19.5 and 20.9); third step included CKD stages 2-5 with either hypertension or proteinuria (OR:44.7); the combination of hypertension and proteinuria was associated with the highest risk, but the low number of cases prevented precise quantification. Limitations: the study was performed in two Centers only. The number of cases with severe CKD is small.

Conclusions: The model may support counselling and clinical management by grading the risk for adverse pregnancy outcomes. Further studies are needed to externally validate the model.

FR-PO595

Solitary Kidney Is Associated with a Higher Risk of Adverse Outcomes in Pregnancy Jessica B. Kendrick,[1,2] John R. Holmen,[3] Gerard John Smits,[1] Michel Chonchol.[1] *[1]Univ of Colorado Denver, Aurora, CO; [2]Denver Health Medical Center, Denver, CO; [3]Intermountain Health Care, Salt Lake City, UT.*

Background: Chronic kidney disease is associated with adverse outcomes in pregnancy. Data regarding the effect of decreased glomerular filtration rate on pregnancy in women with a single kidney primarily has come from studies of kidney transplant recipients and living kidney donors. We set out to determine the risk of adverse outcomes in women with a single kidney from etiologies other than donation.

Methods: Using data from an integrated health care delivery system from 2000 through 2014, we conducted a study of 1,556 pregnant women hospitalized for childbirth. A total of 333 women had a single kidney with normal kidney function and were matched 1:3 by age and race to women with two kidneys. Adverse pregnancy outcomes included preterm delivery, delivery via cesarean section, preeclampsia/eclampsia, length of stay at hospital and low birth weight (<2,500 g). Multivariate logistic regression analysis was used to examine the association between a single kidney and adverse pregnancy outcomes.

Results: Of the women with a solitary kidney, the mean (SD) age and mean (SD) gestational age at delivery was 28±6 years and 38±2 weeks, respectively. Compared to women with two kidneys, those with a single kidney had an increased risk of preterm delivery (OR 2.33, 95% CI 1.61-3.38), delivery via cesarean section (OR 1.85, 95% CI 1.33-2.56), and preeclampsia/eclampsia (OR 1.87, 95% CI 1.23-2.85). Women with a single kidney also had an increased risk of a length of stay > 3 days in the hospital (OR 1.50, 95% CI 1.01-2.20) and low infant birth weight (OR 2.99, 95% CI 1.95-4.59).

Conclusions: Women with a solitary kidney from causes other than kidney donation have a higher risk of adverse outcomes in pregnancy.

FR-PO596

Thiamine Deficiency in Non-Dialysis CKD Patients Yukako Ohyama, Toshikazu Ozeki, Shun Minatoguchi, Hideaki Shimizu, Yoshiro Fujita. *Nephrology and Rheumatology, Chubu Rosai Hospital, Nagoya, Japan.*

Background: Thiamine deficiency is associated with malnutrition, alcoholism and chronic diseases such as cancer. Long use of diuretics also induces thiamine deficiency, which is due to an increased urinary loss of thiamine. Some papers report that thiamine tend to accumulate because of decreased urinary flow in chronic kidney disease (CKD) patients. Others report that a protein restricted diet causes thiamine deficiency in CKD patients. This study aimed to examine the prevalence and factors associated with thiamine deficiency in CKD patients.

Methods: This is a single center cross-sectional study in patients with non-dialysis CKD under regular follw-up in nephrology center of Chubu Rosai Hospital from July 1, 2014 to January 31, 2015. The patients who meet the CKD criteria of Japanese Society of Nephrology were selected. We use the deta from medical records, questionnaires and nutrition surveys.

Results: The study population consisted of 149 patients aged 71.2 ± 10.9 years with estimated GFR of 33.2 ± 18.2 ml/min per 1.73m^2 . They were divided to low thiamine group (serum thiamine level<30ng/ml) and high thiamine group (serum thiamine level³30ng/ml). In univariate comparisons, patients with low thiamine group had significantly lower protein intake which is estimated by the nutrition survey. The use of loop diuretics was not associated with thiamine deficiency. In multivariate analyses, high age, low eGFR and low protein intake, especially less than 0.8g/kg, were independently associated with thiamine deficiency.

	Odds Ratio(95% CI)	P Value
Age (years)	1.12(1.00-1.26)	0.047*
Sex (men)	0.89(0.12-6.45)	0.91
Malignancy (yes)	0.59(0.05-6.49)	0.67
Alcoholism (yes)	0.00(0.00-)	1.00
frosemide (yes)	0.04(0.00-1.22)	0.07
eGFR	0.86(0.75-0.98)	0.02*
protein intake <0.6 g/kg	46.21(1.77-1208.48)	0.02*
protein intake ≥0.6 and <0.8 g/kg	30.93(1.47-649.92)	0.03*
protein intake ≥0.8 and <1.0 g/kg	12.57(0.84-187.20)	0.07
protein intake ≥1.0 g/kg	1.00(reference)	

Conclusions: Protein intake is an important factor for thiamine levels of CKD patients. Protein restriction for CKD patients especially with high age and low eGFR have a high risk of thiamine deficiency.

FR-PO597

Controlled Attenuation Parameter Measured by FibroScan Is Closely Associated with Metabolic Syndrome in Patients with Chronic Kidney Disease Meiyan Wu,[1] Sul A Lee,[2] Chang-Yun Yoon,[2] Tae ik Chang,[3] Shin-Wook Kang,[1,2] Tae-Hyun Yoo.[1,2] *[1]Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [3]Dept of Internal Medicine, NHIC Ilsan Hospital, Gyeonggi-do, Korea.*

Background: Hepatic steatosis can be determined by the measurement of liver controlled attenuation parameter (CAP) using FibroScan. Although the practical methods predicting the risk of metabolic syndrome (MS) development are lacking, recent studies represent that this parameter is closely correlated with the presence of MS in the general population. Therefore, we investigated whether CAP measured by FibroScan could predict the presence of MS in chronic kidney disease (CKD) patients.

Methods: A total of 468 CKD patients were evaluated. MS was defined by using the Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria. Multivariate logistic regression analysis was used to identify the independent association between CAP and MS.

Results: The mean age of the patients was 57.5 years and 225 patients (48.1%) were male. The mean value of CAP was 241.7 dB/m. CAP was independently associated with body mass index (β=7.818, P<0.001), triglyceride (β=0.246, P=0.002) and estimated glomerular filtration rate (eGFR) (β=0.581, P=0.005). MS was diagnosed in 142 (30.3%) patients. In patients with MS, diabetes was more prevalent (59.9 vs. 25.8%, P<0.001), hemoglobin (13.1±2.4 vs. 12.6±2.1 g/dL, P=0.026) and CAP (262.0±60.6 vs. 232.9±49.0 dB/m, P<0.001) levels were significantly higher, while eGFR (82.9±27.5 vs. 91.6±26.0 mL/min/1.73m^2, P=0.001) was lower compared with patients without MS. Multivariate logistic regression analysis revealed that high CAP levels were independently correlated with the increased risk of MS (per 1 dB/m increase, odds ratio=1.010, 95% confidence interval=1.002-1.018, P=0.014) after adjustment for confounding factors.

Conclusions: High CAP levels measured by FibroScan were significantly associated with an increased risk of MS in CKD patients. These data suggests liver FibroScan could be a practical method for evaluating he risk of MS development in CKD patients.

FR-PO598

Outcomes in Women Switched from Mycophenolate to Azathioprine in Advance of Pregnancy Kate S. Wiles,[1] Adam D. Jakes,[2] Asra Alwandi,[1] Kate Bramham,[1] Paramit Chowdhury,[1] Lucy C. Chappell,[1] Catherine Nelson-piercy,[1] Liz Lightstone.[2] *[1]Guy's and St. Thomas' NHS Foundation Trust; [2]Imperial College London.*

Background: Mycophenolate is teratogenic and should be replaced in advance of pregnancy. There is concern that this change may have adverse consequences including transplant rejection and disease flare. The aim of this study was to determine the risk of adverse outcome in women switched from mycophenolate to azathioprine.

Methods: Records of women attending regional renal pre-pregnancy counselling clinics 2011-2014 were examined. Women taking mycophenolate were included and the decision to switch to azathioprine reviewed. Outcomes were a decline in eGFR within a year, renal biopsy, disease flare or rejection, and conversion back to mycophenolate. Pregnancy outcomes were analysed.

Results: Data were available for 60 women (31 kidney transplant, 4 kidney-pancreas transplant and 25 glomerulonephitis, predominantly lupus). Most women were considered eligible for a switch to azathioprine and one woman chose to switch against advice.

Decision to switch	**n**	**%**
Yes	44	73
No: Unstable graft function	7	12
No: No immediate plans for pregnancy	5	8
No: Active lupus	2	3
No: Advanced renal dysfunction as a barrier to pregnancy	2	3

There was a mean fall in eGFR of 4.8ml/min/1.73m^2/year in the women who did not conceive within 12 months of the switch (n=26). This decline included two flares of biopsy-confirmed lupus nephritis and one case of progressive antibody mediated rejection in the woman advised not to switch. 3/45 (7%) of women had a renal biopsy. There were no cases of acute rejection. 10/45 (22%) of women were converted back to mycophenolate, 3 empirically and 7 with a clinical indication. There were 14 pregnancies. 63% were complicated by pre-existing hypertension or pre-eclampsia. 67% of women had a Caesarean delivery and 33% of babies were preterm (<37 weeks).

Conclusions: Most women taking mycophenolate can be converted to azathioprine. Drug switch was not associated with acute rejection, but lupus flare did occur. Most women did not require conversion back to mycophenolate. Pre-eclampsia and pre-term delivery are associated with chronic kidney disease and are not thought to be due to medication use.

FR-PO599

Chronic Kidney Disease Linearly Predicts Outcomes After Elective Total Joint Arthroplasty Edward J. Filippone,[1] Timothy L. Tan,[1] Dean D. Tan,[1] Michael M. Kheir,[1] Antonia F. Chen.[1] *[1]Medicine, Thomas Jefferson Univ, Philadelphia, PA; [2]Orthopedics, Thomas Jefferson Univ.*

Background: Kidney disease has been widely associated with increased complications in total joint arthroplasty (TJA). The purpose of this study is to determine the association of kidney disease severity as measured by the chronic kidney disease (CKD) staging system with complications and outcomes after TJA.

Methods: A retrospective review of an institutional database of 12,308 primary TJAs (6,361 hips and 5,947 knees) from 2008 to 2013 was performed. The following preoperative variables were obtained from medical records: chemistry 7 panel, Elixhauser comorbidities, and demographic factors. CKD stages were defined based on estimated glomerular filtration rate in ml/min/1.73m^2 (eGFR): (1) 90+, (2) 60-89, (3A) 45-59, (3B) 30-44, (4) 15-29, and (5) <15. Multivariate analysis was performed to assess the independent influence of CKD stage on the aforementioned endpoints.

Results: Patients with CKD stage greater than 2 demonstrated an increased risk of transfusions (CKD 3A odds ratio [OR]: 1.67, CKD 3B OR: 2.80, CKD 4 OR: 2.24), length of stay greater than 3 days (CKD 3A OR: 1.34, CKD 3B OR: 1.39, CKD 4 OR: 3.57), and in-hospital complications (CKD 3A OR: 1.21, CKD 3B OR: 1.80, CKD 4 OR: 3.36) compared to all patients with eGFR > 60. Additionally, the relationship between eGFR and the above complications were found to increase linearly rather than exponentially at a certain threshold. In contrast, CKD stage was not associated with septic or aseptic revisions.

Conclusions: Severe CKD is associated with an increased risk of transfusion, length of stay, and in hospital complications. Rather than finding a clear threshold, complications increased linearly with disease severity. Surgeons should be cognizant of this increase when evaluating TJA patients with renal disease.

FR-PO600

The Assessment of Incidental Risk for Microalbuminuria According to the Level of Depression Scale Dong-Young Lee,[1] Younjoo Jung,[1] Beom Kim,[1] Kyoung Hyoub Moon,[1] Sung Keun Park.[2] *[1]Internal Medicine, VHS Medical Center, Seoul, Korea; [2]Total Health Care, Kangbuk Samsung Hospital, Seoul, Korea.*

Background: Depression is one of the most common psychiatric disorders. The burden of disease for depression goes beyond function and extends to somatic health. A growing body of evidence shows that depression is significantly associated with chronic kidney disease. Nonetheless, the incidental relationship between microalbuminuria and depression was not identified yet. Therefore, we conducted this study to investigate incidental relationship of microalbuminura with depression scale.

Methods: This study was conducted for 45,293 Korean men and their spouses without microalbuminuria who got medical health check up in Kangbuk Samsung Total healthcare center in 2010. To assess the degree of their depression, Center for Epidemiologi Studies-Depression Scale (CES-D) was used (CES-D ≤ 15: normal, CES-D 16-20: moderate risk group, CES-D > 21: high risk group). On the basis of CES-D score in 2010, they were classified into 3 groups (normal, moderate, high risk group) and monitored for the development of microalbuminuria from January, 2011 to April, 2015.

Results: While the general incidence was 1.7%, the incidence of microalbuminuria increased in proportion to the risk score of depression evaluated by CES-D (CES-D ≤ 15: 0.4%, CES-D 16-20: 1.8%, CES-D > 21: 3.6%). When the hazzard ratio (HR) of normal group (CES-D ≤ 15) was set to reference value (HR: 1.00), the HRs for microalbuminuria also increased according to the score of CES-D scale. In addition, these associations were preserved even after adjusting for the various metabolic covariates such as age, physical activity, total cholesterol , LDL-cholesterol, triglyceride, body mass index, and obesity [CES-D 16-20: 1.98, CES-D > 21: 3.37).

Conclusions: Our study showed that the risks of microalbuminuria in proportion to the severity of depression. These findings imply the clinical role of the depression for

development of the microalbuminuria. Especially, considering the clinical significance of microalbuminuria as an early predictor of health outcomes related to chronic kidney disease, our study implications can be expanded to other diseases entity.

FR-PO601

Outcomes in CKD Patients with Hospital Acquired Complications Babak Bohlouli,[1] Terri Jurgens Jackson,[2] Marcello Tonelli,[3] Scott Klarenbach.[1] *[1]Medicine, Univ of Alberta, Edmonton, AB, Canada; [2]Northern Clinical Research Centre, Univ of Melbourne, Epping, Vic, Australia; [3]Medicine, Univ of Calgary, Calgary, AB, Canada.*

Background: Patients with CKD are at increased risk of hospital acquired complications (HACs) including those considered preventable. The impact of HACs on patient and health system outcomes has not been well described.

Methods: Subjects hospitalized from April 1, 2003 to March 31, 2008 from a population based cohort (Alberta Kidney Disease Network) were studied. Outpatient eGFR and proteinuria (protein/creatinine ratio or dipstick) in the year prior to index hospitalization were used to define CKD status. Co-morbid conditions were identified using validated algorithms applied to administrative data. ICD 10 CA was used to classify reason for admission. A specific diagnostic indicator (type II) was used to identify hospital acquired complications (HACs) that were sub-classified as "potentially" and "always" preventable. We studied the following outcomes: re-admission within 90 days of discharge, all cause mortality at 90 days, and index hospitalization costs. Multivariable regression models examined the association of HACs with re-admission, mortality, and incremental health care costs, accounting for confounders.

Results: Of 536,549 subjects, 45,377 (8.5%) with CKD were hospitalized. In patients with HACs, the OR of re-admission and death at 90 days was 1.37 (95% CI: 1.32 – 1.43), and 3.31 (95% CI: 3.06 – 3.58) respectively compared with those without HAC. Hospitalizations with any HAC were associated with median incremental health costs of $4028 (95% CI: $3898 – $4158). A graded association was observed for those outcomes with increasing number of HACs and severity of CKD. Similar results were noted when only potentially preventable HACs were considered.

Conclusions: Complications occurring during hospitalization in patients with CKD is independently associated with an increased risk of hospital re-admission, health care costs, and mortality. Targeted strategies to reduce HACs in this patient population may have a significant benefit.

FR-PO602

Plasma Proteins Associated with Declining Renal Function in Patients with Type 1 Diabetes: Results of a Global Proteomic Analysis Using SOMAscan Platform Andrew L. Schlafly, Monika A. Niewczas, Marcus G. Pezzolesi, Andrzej S. Krolewski. *Joslin Diabetes Center, Boston, MA.*

Background: Increases in serum creatinine and cystatin C are considered measures of declining renal function in patients with diabetes.

Methods: To search for other proteins correlated with declining renal function, we conducted a follow-up study, following 30 patients with T1D and proteinuria for 1-3 years. Mean eGFR was 67 ml/min at baseline, and was 59 ml/min at the end of follow-up. Plasma concentrations of circulating proteins were measured on the SOMAscan platform at baseline and at the end of follow-up. The platform measured 954 proteins for each of the 30 patients, with median limit of detection (LOD) of 1.6pg/mL,dynamic range of 8 logs, and median coefficient of variation (CV) of 5% for individual proteins measured repeatedly in replicate runs of plasma samples.

Results: Renal function change during follow-up in each patient was expressed as the difference between eGFRcre at baseline and at follow-up and was referred to as ΔGFR (mean: -7.7 ml/min, range: -44 ml/min to 11 ml/min). For each protein, the Spearman rank correlation coefficient between ΔGFR and the percent change in the protein's level (RFU) was used to measure the protein's association with renal function decline. In 27 proteins, concentrations increased with decreasing renal function (r: -0.67 to -0.46, p<0.01). In 16 proteins, concentrations decreased with decreasing renal function (r: 0.46 to 0.57, p<0.01). The top 5 proteins in each category are shown below.

Negatively correlated proteins:			Positively correlated proteins:		
Name	$r_{Spearman}$	P	Name	$r_{Spearman}$	P
IL-17F	-0.67	5.5E-05	ATS1	0.57	1.0E-03
ARMEL	-0.62	2.2E-04	CDC2	0.54	2.2E-03
TNFRSF19L	-0.62	2.4E-04	FGF6	0.53	2.6E-03
TNFRSF1A	-0.57	1.1E-03	CA1	0.50	4.7E-03
Cystatin C	-0.56	1.1E-03	CDH12	0.50	4.8E-03

Conclusions: In conclusion, increasing or decreasing concentrations of plasma proteins with eGFR loss may reflect worsening renal function, as is the case with cystatin C. However, changes in plasma concentration of these proteins may represent the extent and intensity of the disease process underlying progressive renal decline, which is most likely the case with IL-17F and the TNFR's.

Mass Spectrometry Imaging Reveals Disease Specific Alterations in Protein Abundance in Human Diabetic Nephropathy Haichun Yang,[1] Audra M. Judd,[2] Michelle Reyzer,[2] Jeremy L. Norris,[2] Richard M. Caprioli,[2] Raymond C. Harris,[3] Agnes B. Fogo.[1] *[1]Pathology, Microbiology and Immunology, Vanderbilt Univ; [2]Mass Spectrometry Research Center, Vanderbilt Univ; [3]Nephrology, Vanderbilt Univ, Nashville, TN.*

Background: Diabetic nephropathy (DN) is a major complication in diabetic patients. However, progression and albuminuria are variable among patients with DN. Matrix-assisted laser desorption/ionization imaging mass spectrometry (MALDI) is a technology that acquires molecular information from thin tissue sections in a spatially-defined manner. We examined MALDI mass spectra to discover alterations in protein expression in human DN glomeruli, and compared to the morphology and clinical features.

Methods: DN biopsies (n=36) and normal kidney (n=9) were assessed. DN cases were divided into mild, moderate and severe, based on biopsy findings. Follow-up was available in 23 patients, and patients were sub-grouped into stable DN (decreased eGFR ≤50%, n=13) vs. progressive DN (decreased eGFR >50%, n=10). Peptide mass spectra were acquired over the mass-to-charge range 600-4500 from at least 12 glomerular areas per case.

Results: DN patients had reduced eGFR and increased proteinuria, compared to normal. Mass spectrometry showed 168 peptide peaks, with 8 peaks increased and 21 peaks decreased in DN compared to Normal. Moderate and severe DN showed more nodular glomerulosclerosis than mild DN by study design (moderate 2.13±0.10, severe 2.17±0.22 vs. mild 0.43±0.30, 0-4+ scale, p<0.05) and mesangial expansion (moderate 1.97±0.09, severe 2.28±0.15 vs. mild DN 1.21±0.15, p<0.05). Peptide maps were more similar in moderate vs severe DN groups, compared to mild DN. Thirteen of 168 peptide peaks were significantly different among three groups. In progressive DN, 10 peptide peaks were decreased and 1 was increased, compared to stable DN. Of note, these peaks differed from those associated with the morphologic phenotype.

Conclusions: We conclude that different peptide maps correlate with DN onset, severity and prognosis, and that clinical and morphological phenotypes have differing proteomic correlates. These peptides will now be further validated and identified by MS/MS fragmentation and database searching.

Urine Metabolomic Profiling Reveals a Unique Signature for Type 2 Diabetes Jane J. Kim, Rintaro Saito, Satoshi Miyamoto, Minya Pu, Loki Natarajan, Kumar Sharma. *Univ of California, San Diego.*

Background: Increased circulating branched chain amino acids (BCAAs) are associated with type 2 diabetes (T2D) and insulin resistance. However, it is not clear whether increased plasma BCAA concentrations result from increased synthesis, or impaired degradation or excretion. Here, we employ a targeted metabolomics approach to evaluate diabetic patients without overt kidney disease to identify urine metabolites associated with T2D, presenting potential urine biomarkers for clinical prediction and further insight into disease pathogenesis.

Methods: We measured 105 urine metabolites by GC/MS in a screening T2D cohort (n=27), validation T2D cohort (n=14), and healthy control group (n=23). We also examined kidney cortex of *db/db* and control *db/m* mice to measure gene expression by Illumina microarray and protein expression by western blot.

Results: Following FDR correction, 57 metabolites were found to be different in the screening cohort compared to controls. When these 57 metabolites were carried forward for analysis in a validation T2D cohort, 24 of these urine metabolites were confirmed to be different from controls using Bonferroni adjustment for multiple comparisons. 16 of the 24 significant metabolites were amino acids, and 8 of these represented BCAA degradation products. To further investigate BCAA metabolism, we examined kidney tissue from *db/db* mice and found that the gene expression of key enzymes related to BCAA catabolism was decreased. Western blot studies confirmed that renal expression of branched-chain ketoacid dehydrogenase, a mitochondrial enzyme complex that catalyzes an irreversible step in BCAA catabolism, was reduced in *db/db* mice compared with controls.

Conclusions: Prior studies have reported impaired mitochondrial BCAA metabolism in adipose, muscle and liver. However, our results show a robust pattern of increased BCAA metabolites, likely reflecting increased BCAA catabolism and/or increased metabolic flux. The reduced renal expression of BCAA enzymes supports a role for dysregulated BCAA metabolism by the kidney. The elevated BCAA metabolites may have an affect on regulating insulin resistance and the development of kidney disease with T2D.

Urinary Matrix Metalloproteinase Activities Are Associated with Renal Hyperfiltration in Adolescents With Type 2 Diabetes Petter Bjornstad,[1] Laura Pyle,[3] Janet Snell-bergeon,[1] Karen S. Moulton,[2] Kristen Nadeau.[3] *[1]Barbara Davis Center for Diabetes; [2]Univ of Colorado Denver; [3]Children's Hospital Colorado.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease. Matrix metalloproteinases (MMP) modify extracellular matrix during vascular remodeling and are known to be elevated in diabetes, and associated with DN in type 1 diabetes. We hypothesized that activities of latent MMP and neutrophil gelatinase-associated lipocalin (NGAL) proteins in urine would be associated with microalbuminuria and hyperfiltration in adolescents with type 2 diabetes (T2D).

Methods: 295 adolescents with T2D (14.0±1.8 years, <2 years duration, BMI ≥85%, and HbA1c ≤8%) in the Treatment Options for Type 2 Diabetes in Adolescents and Youth (TODAY) study had urine and blood evaluated at baseline and annually for 5-years. MMP2, MMP9 and NGAL activities were measured by gelatin zymography and normalized to urine creatinine. Microalbuminuria was defined as albumin-to-creatinine ratio (ACR) ^{3}30mg/g. Estimated GFR was calculated by Schwartz (eGFR=36.5*height/creatinine) and hyperfiltration defined as ^{3}135mL/min/1.73m^2. Mixed models evaluated the longitudinal relationships between MMP-2, MMP9 and NGAL with eGFR, ACR, hyperfiltration and microalbuminuria respectively. MMP2, MMP9 and NGAL-MMP9 activities were natural log-transformed (ln) due to skewed distribution.

Results: MMP2, MMP9 and NGAL-MMP9 were associated with eGFR, but not ACR over time after adjusting for age, sex, HbA1c, SBP and treatment group. One standard deviation increase in ln MMP2, ln MMP9 and ln NGAL-MMP9 were each associated with a greater odds of having microalbuminuria and hyperfiltration over time, respectively.

Table Mixed-logistic regression models

	Hyperfiltration		Microalbuminuria	
	OR*, 95% CI, P-value			
MMP2	**1.3** (1.1-1.5)	0.001	**1.6** (1.3-1.9)	<0.0001
MMP9	**1.2** (1.0-1.4)	0.046	**1.4** (1.2-1.7)	0.001
NGAL-MMP9	**1.2** (1.0-1.5)	0.03	**1.4** (1.1-1.7)	0.004

*Odds ratio of hyperfiltration or microalbuminuria per 1 SD increase in natural log transformed variable adjusted for age, sex, SBP, HbA1c and treatment group

Conclusions: In conclusion, urinary MMP and NGAL activities were associated with early DN in adolescents with T2D over time.

A Serum Metabolite Classifier Predicts Response to ARBs in Diabetes Michelle Pena,[1] Bernd Mayer,[2] Andreas Heinzel,[2] Peter Rossing,[3] Hiddo Jan Lambers Heerspink.[1] *[1]UMC Groningen; [2]Emergentec Biodevelopment; [3]Steno Diabetes Center.*

Background: Individual patients show a large variability in albuminuria response to Angiotensin Receptor Blockers (ARB). Identifying novel biomarkers that predict ARB response may help optimize treatment. We aimed to discover and validate a novel serum metabolite classifier that predicts response in urinary albumin excretion (UAE) to ARBs in diabetes.

Methods: Flow injection analysis/liquid chromatography-tandem mass spectrometry based targeted metabolomics was performed on serum samples from type 2 diabetes patients (n=49) enrolled in a clinical study assessing the effect of irbesartan 300mg/day. Individual serum metabolites were selected with LASSO regression to predict UAE response to irbesartan. The classifier was developed with ridge regression. Improvement in risk prediction was tested on top of a control model (age, sex, HbA1c, SBP, GFR, UAE) by assessing differences in explained variation (R^2) between the control model and the classifier model. The classifier was externally validated in a clinical study in type 1 diabetes patients (n=50) testing the effect of losartan 100mg/day. Metabolite mapping was performed on a molecular model of diabetic kidney disease to identify underlying molecular processes contributing to ARB response.

Results: The classifier included 21 metabolites. Median reduction in UAE was -42% [-69,-8] in type 2 diabetes. The classifier was significantly associated with UAE response to irbesartan (p<.001) and significantly improved prediction of UAE response on top of the control model (R^2 increase from 0.10 to 0.69; p<.001). In the external validation cohort, median reduction in UAE was -43% [-62,-23]. The classifier significantly improved prediction of UAE response to losartan (R^2 increase from 0.17 to 0.52; p<.001). Metabolites included in the classifier were assigned to stress/inflammation pathways and downstream consequences of fibrosis and extra cellular matrix remodeling. Moreover, ADMA, impacting eNOS activity, appears to be a specific factor relevant in ARB response.

Conclusions: A classifier of 21 serum metabolites was identified and externally validated to significantly improve prediction of albuminuria response to ARBs in diabetes.

Is Urinary Proteomics Useful to Predict Retinopathy in Type 2 Diabetic Patients in the DIRECT 2 Study Mie K. Eickhoff,[1] Marie Frimodt-Moller,[1] Morten Lindhardt,[1] Mohammed Dakna,[2] Harald Mischak,[2,3] Direct Steering Group,[5] Peter Rossing.[1,4] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Mosaiques Diagnostics GmbH, Hannover, Germany; [3]BHF Glasgow Cardiovascular Research Centre, Univ of Glasgow, Glasgow, United Kingdom; [4]HEALTH, Univ of Aahus, Denmark; [5]Univ College London, London, United Kingdom.*

Background: Diabetic microvascular complications affect the kidney and the eyes, being a leading cause of renal failure and blindness. Urinary proteomics has shown promise as an early indicator of future development of diabetic nephropathy. Here we investigate if this could also predict progression of diabetic retinopathy.

Methods: In a post-hoc study of the DIRECT 2 study, a randomized, controlled clinical trial of candesartan for prevention of retinopathy, we studied patients with type 2 diabetes and normoalbuminuria (n=792), followed for a mean of 4.7 years. We address the predictive ability of a previously defined CKD risk score based on proteomic measurement of 273 urinary peptides (CE-MS). We also assessed the possibility of a new EYEscore based on discriminative features choosen out of 1161 peptides in a training set of 528 patients. Progression were either 2 step (E2) (primary) or 3 step (E3) change in retinopathy on the concatenated Early Treatment Diabetic Retinopathy Study severity scale.

Results: Progression of retinopathy was seen in 37% of E2 and 19% of E3 patients. None of the peptides were significantly differentially expressed in cases vs control. In Cox models five peptides were associated with E3 but not E2 in the training set but were not validated. The CKD risk score was able to predict E3 (HR 1.54 95% CI 1.02 to 21.34, p=0.042) but not E2 (HR 1.14 p=0.34) during follow-up, independent of treatment (candesartan/placebo), age, gender, systolic BP, baseline UAER, baseline eGFR, HbA_{1c} and diabetes duration.

Conclusions: In this cohort of patients with type 2 diabetes and normoalbuminuria from a large intervention study, the CKD classifier was an independent predictor of severe but not mild progression in retinopathy. It was not possible to develop a retinopathy specific marker panel with clinically relevant accuracy.

Funding: Pharmaceutical Company Support - The DIRECT study was jointly funded by AstraZeneca and Takeda.

Urine Exosomal Analysis Reflects Underlying Kidney Pathology Better Than Whole Urine Analysis Krishnamurthy P. Gudehithlu,[1] Ignacio Garcia-Gomez,[4] Jane Vernik,[1,2] Carolyn S. Brecklin,[1,3] Mark A. Kraus,[1,2] David J. Cimbaluk,[2] Peter D. Hart,[1,2] George Dunea,[1,3,4] Jose A.L. Arruda,[1,3,4] Ashok K. Singh.[1,3,4] *[1]Div of Nephrology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL; [2]Dept of Internal Medicine, Rush Univ Medical College, Chicago, IL; [3]Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL; [4]The Hektoen Inst of Medicine, Chicago, IL.*

Background: Predicting or diagnosing underlying kidney pathology by analyzing whole urine has remained unrealized. This is because whole urine mostly represents proteins from the plasma and little from the kidney. Urinary exosomes, on the other hand, being kidney-derived, contain proteins of the kidney. We experimentally tested the hypothesis, **'urine exosomal proteome more truly represents the underlying pathology of kidney disease than a whole urine based analysis.'** Comparison between whole urine and urine exosomal gelatinase and ceruloplasmin, two kidney disease markers, was performed on normal and diabetic kidney disease patients.

Methods: Urinary exosomes were separated from urine by ultra-centrifugation. Gelatinase, an enzyme which measures matrix degrading activity collectively from several matrix metalloproteinases (mainly MMP-2, 9), was measured by an activity assay using fluorosceinated gelatin as the substrate, and ceruloplasmin, an oxido-reductase enzyme involved in iron metabolism, was measured by sandwich ELISA. Biopsies were immunostained for MMP-9 and ceruloplasmin.

Results: We found that changes in both, gelatinase (decreased activity; 20-50%; p<0.05) and ceruloplasmin (increased levels; 300%; p<0.05), in the urinary exosomes of diabetic kidney patients were in agreement with the alterations of these two proteins in the kidney tissue as judged by immune-staining. In contrast, the levels of these two proteins in the whole urine were highly variable (p=NS) and in disagreement with the results of immune-staining.

Conclusions: In conclusion, our findings support our hypothesis that protein markers found in urinary exosomes better reflect the changes in the kidney than protein measurements carried out in whole urine samples.

FR-PO609

Neutrophil Gelatinase Associated Lipocalcin as an Early Biomarkers of Nephropathy in Diabetic Patients and Effect of RAAS Blockade on NGAL as Marker of Tubular Damage in Diabetic Nephropathy Anupama Kaul, Dharmendra Bhadauria, Narayan Prasad, Amit Gupta, Raj K. Sharma. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, India.*

Background: T2DM is the primary cause leading to kidney disease . Novel, more sensitive biomarkers that may be used to detect diabetic nephropathy at an early stage, and possibly also detect disease progression or regression after drug therapy.

Methods: • -150 Diabetic patients were enrolled in the study from nephrology and endocrinology OPD at Sanjay Gandhi Post Graduate Institute Of Medical Sciences ,lucknow India from 2012-14, 50 each of normo-,micro- and macroalbuminuric with 50 normal healthy control. Serum NGAL and cystatin C were measured at enrollment and after 12-15 months. ACEI as intervention was given in all normo hypertensive ,microalbuminuric and macroalbuminuric Diabetics and after follow up period 1 year repeat NGAL levels assessment. Normoalbuminuric ,normotensive individuals with raised NGAL at the baseline and follow up after 1 year were assessed.

Results: • As compared to control population the normoalbuminuric Diabetics had higher serum as well as urinary NGAL levels but lesser than microalbuminuria.Mean NGAL levels were not significantly different between Normoalbuminuric diabetes and controls. At re-evaluation, mean NGAL value and mean eGFR value in patients with diabetes had increased (p=0.078 and p=0.006 respectively). At both baseline and reevaluation, NGAL positively correlated with cystatin C (p<0.001) and creatinine (p=0.010). NGAL correlated negatively with eGFR(r=-0.26, p=0.049) .Among micro,macroalbuminuric diabetics the baseline urine albumin excretion rate was significantly correlated with the rate of eGFR

decline ($P<.0.004$). The baseline serum NGAL levels were also correlated with the rate of eGFR decline ($P = 0.066$). During ACE inhibitor treatment ie Ramipril 5mg daily , urine-NGAL was reduced (95% CI) 11% (not significant).

Conclusions: Urine-NGAL are elevated in Type 2 diabetic patients, with or without albuminuria, indicating tubular damage at an early stage. ACE inhibitor Ramipril reduced urine-NGAL predominantely in Micro/macroalbuminuric diabetic patients .

FR-PO610

Mechanism of Increased Urinary Full-Length Megalin Excretion in Type 2 Diabetes Mellitus Patients with Nephropathy Shankhajit De,[1] Shoji Kuwahara,[2] Michihiro Hosojima,[3] Tomomi Ishikawa,[1] Ryohei Kaseda,[3] Yusuke Yoshioka,[4] Yoshiki Suzuki,[5] Ichiei Narita,[1] Takahiro Ochiya,[4] Akihiko Saito.[2] *[1]Clin Nephrol & Rheumatol, Niigata Univ, Niigata, Japan; [2]Applied Mol Med, Niigata Univ, Niigata, Japan; [3]Clin Nutr Sci, Niigata Univ, Niigata, Japan; [4]Mol & Cell Med, NCCRI, Tokyo, Japan; [5]Health Admn Center, Niigata Univ, Niigata, Japan.*

Background: Megalin, an endocytic receptor of proximal tubule cells (PTCs), is excreted into urine in both of the extracellular domain and the full-length forms. Previously we developed urinary ELISA systems to measure the two forms of megalin and found that the excretion of the full-length form, mainly present in the insoluble urinary fraction, may be a candidate biomarker for the progression of diabetic nephropathy (DN). We thus aimed to investigate the molecular mechanism of urinary excretion of the full-length form of megalin.

Methods: Megalin content of urinary extracellular vesicles (EVs) from normal control and type 2 diabetes mellitus (T2DM) patients with different albuminuria stages were measured by western blotting. By immunoelectron microscopy and Nanoparticle Tracking Analysis using NanoSight®, we characterized the size and number of the EVs. To study increased EVs excretion *in vitro*, we cultured immortalized rat proximal tubule cells (IRPTCs) and treated with advanced glycation end products-modified bovine serum albumin (AGEs).

Results: The number of urinary EVs excretion is increased in T2DM patients in comparison with the normal control subjects in a correlation with the progression of DN. The megalin content of the EVs are also increased in those patients, indicating increased excretion of PTC-derived EVs in DN condition. However, other tubular segment markers in EVs are not well correlated with the disease progression. By immunoelectron microscopy we found that megalin is excreted through the smaller vesicles which are likely to be exosomes in nature. Treatment on IRPTCs with AGEs for 24h causes lysosomal dysfunction which subsequently increases multivesicular body formation as well as release of megalin-containing exosomes.

Conclusions: Exocytosis-mediated urinary excretion of full-length megalin via exosomes might be a useful biomarker for early detection and progression of DN.

FR-PO611

Urinary Excretion of Kidney Aquaporins as Possible Biomarker of Diabetic Nephropathy Luigi Rossi,[1] Maria Celeste Nicoletti,[2] Monica Carmosino,[2] Antonella Di Franco,[1] Francesca Indrio,[1] Rosa Lella,[1] Luigi Laviola,[1] Maria Svelto,[2] Loreto Gesualdo,[1] Giuseppe Procino.[2] *[1]DETO, Univ of Bari, Bari, Italy; [2]Dept of Biosciences, Biotechnologies and Biopharmaceutic, Univ of Bari, Bari, Italy.*

Background: Diabetic nephropathy (DN) is is classified into four hierarchical glomerular lesions on the basis of histological analysis of kidney biopsies. This is clearly a highly invasive diagnostic approach numerous studies have been conducted to identify a non-invasive biomarker of the disease, but none of these is considered to be sufficiently specific and sensitive Experimental evidences showed that the water channel aquaporins (AQP), expressed at the plasma membrane of epithelial cells lining in the kidney tubule, are often dysregulated during DN. Interestingly, apical membrane protein are excreted in the urinary space as nano-scale exosome vesicles, to an extent proportional to their amount expressed at the plasma membrane, thus allowing their quantitation in urine samples.

Methods: In this work we compared excretion of AQP5 and AQP2 (uAQP5 and uAQP2) in the urine of 35 diabetic patients: 12 with histological diagnosis of DN, 12 with with normal renal function and normoalbuminuric DM (D) and 11 with non-diabetic nephropathy (NDN). Both proteins were quantified by ELISA method on urine samples and the results were validated by Western blotting analysis on the exosome fraction isolated by ultracentrifugation.

Results: BothELISA and Western blotting analysis independently showed that uAQP5 was three- to fourfold higher in DN patients (7458 ± 2576, p <0.05) compared to the other two groups (D 847,2 ± 70,51; NDRD1882 ± 215). uAQP5 was not statistically different between D and NDN patients. Strikingly, uAQP5 dramatically increased in parallel with the clinical severity of DN. The same analysis showed comparable results for uAQP2.

Conclusions: Our data showed, for the first time, that uAQP5 and uAQP2 dramatically and specifically increase in patients with DN and positively correlate with the histological class of DN. Taken together these data suggest a possible role of AQP5 and AQP2 as novel non-invasive biomarkers to help diagnosing DN and classifying its histological stage.

FR-PO612

Urinary Neutrophil Gelatinase-Associated Lipocalin as Complementary to Albuminuria Biomarker of Early Stage Diabetic Kidney Disease in Type 2 Diabetes Agnieszka Gala-Bladzinska,[1] Paulina Dumnicka,[2] Agnieszka Zylka,[1] Beata Kusnierz-cabala,[3] Marek Kuzniewski.[4] *[1]St' Queen Jadwiga District Hospital No 2, Rzeszów, Poland; [2]Dept of Medical Diagnostics, Jagiellonian Univ Medical College, Kraków, Poland; [3]Dept of Diagnostics, Chair of Clinical Biochemistry, Jagiellonian Univ Medical College, Kraków, Poland; [4]Dept of Nephrology, Jagiellonian Univ Medical College, Kraków, Poland.*

Background: Two clinical phenotypes of diabetic kidney disease (DKD) have been reported, i.e. with or without increased albuminuria. The aim of this study was to assess the usefulness of uNGAL for the preclinical diagnosis of DKD in the course of diabetes mellitus type 2 (DMt2).

Methods: The study group consisted of 115 DMt2 patients (63F, 58M) aged 18 and over (62±14), with normal to moderately increased albuminuria (i.e. urine albumin/creatinine ratio (UACR) <300 mg/g) and eGFR (CKD-EPI) ≥60ml/min/1.73m². Control group included 22 non-diabetic persons with comparable age (57±14; p=0.1) and sex (9F, 13M; p=0.5), and with similar comorbidities. Urine concentrations of NGAL, albumin and creatinine (uCr) were measured in the first morning urine sample. Urine albumin/creatinine ratio (UACR), and analogically, uNGAL/uCr were calculated.

Results: In control group, maximum uNGAL/uCr was 39.64 µg/g. In DMt2 group, 24 patients (21%) had higher results, with the maximum value of 378.6 µg/g. Twenty three (20%) of DMt2 patients had UACR >30 mg/g; of those, 11 had uNGAL/uCr >39.64 µg/g. Among patients with uNGAL/uCr >39.64 µg/g, 13 did not have markedly increased albuminuria (UACR in those patients ranged from 2.35 to 16.10 mg/g). Women with DMt2 had significantly higher uNGAL/uCr than men (median 28.06; IQR 9.05-65.60 versus 11.40; 3.36-18.02 µg/g; p<0.001), without significant difference in UACR (p=0.09). uNGAL/uCr in DMt2 patients correlated significantly with HbA1c (R=0.28; p=0.013), however, it did not correlate with eGFR (R=-0.54; p=0.1), age (R=0.14; p=0.1), or time from DMt2 diagnosis (R=0.13; p=0.1).

Conclusions: Increase in urine NGAL and uNGAL/uCr may indicate early tubular damage particularly worse diabetes control patients, especially female with DMt2.

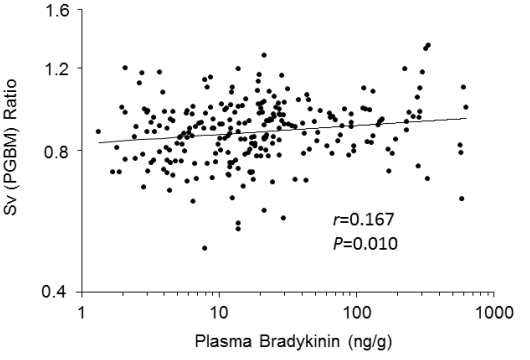
Plasma Bradykinin and Early Diabetic Nephropathy in Type 1 Diabetes Mellitus E. Jennifer Weil,[1] Gudeta D. Fufaa,[1] Robert G. Nelson,[1,6] Michael Merchant,[4,6] Brad H. Rovin,[2,6] Michael Mauer,[3,6] Jon B. Klein.[4,5,6] *[1]NIDDK; [2]Ohio State Univ; [3]Univ of Minnesota; [4]Univ of Louisville; [5]Robley Rex VAMC; [6]for the CKD Biomarkers Consortium.*

Background: Bradykinin (BK) and its modified forms are potential biomarkers of diabetic nephropathy (DN). We examined their association with development of DN lesions in normoalbuminuric normotensive subjects with normal or increased glomerular filtration rate (GFR) and type 1 diabetes (T1D) from the Renin-Angiotensin System Study (N Engl J Med 2009;361:40-50).

Methods: Plasma concentrations of BK and modified BKs were measured at baseline by a quantitative mass spectrometry-based multiple reaction monitoring assay in samples from 246 subjects who underwent kidney biopsies at baseline and after 5 years. Relationships of BK and modified BKs with morphometric variables were assessed using multiple linear regression after adjustment for age, sex, T1D duration, HbA1c, mean arterial pressure, albumin excretion rate (AER) and GFR (iohexol).

Results: Baseline mean age was 29.8 years, mean duration of T1D 11.3 years, median AER 5.1 mg/min, and mean GFR 128 mL/min/1.73 m². After multivariable adjustment, higher BK concentration was associated with the peripheral glomerular basement membrane surface density 5-year/baseline ratio (partial r=0.167, P=0.010; figure) and with the 5-year measurement alone (partial r=0.179, P=0.006). BK was not associated with other morphometric variables and modified BKs were not associated with any of these variables.



Conclusions: Elevated plasma BK concentration measured before clinical findings of DN in people with T1D was associated with increased peripheral glomerular basement membrane surface density, suggesting that it may reflect an adaptive response to early glomerular changes in DN.

FR-PO614

Serum Omentin and Progression of Diabetic Nephropathy Tetsuharu Oku, Fumihiko Furuya, Takeyuki Takamura, Kenichiro Kitamura. *Third Dept of Internal Medicine, Univ of Yamanashi, Chuo, Yamanashi, Japan.*

Background: A novel adipokine, omentin, preferentially produced by visceral adipose tissue compared with subcutaneous adipose tissue. Animal experiments indicated that treatment with recombinant omentin enhanced insulin-stimulated glucose uptake in subcutaneous and omental adipocytes. Furthermore, serum omentin levels are decreased in obesity and diabetics. The purpose of this study was to elucidate whether serum omentin is associated with progression of diabetic nephropathy in diabetic patients.

Methods: The prospective follow-up study; 114 diabetes patients were followed for 5.0 ± 1.1 years. Patients were divided at baseline into three groups according to their urinary albumin-to-creatinine ratio (UACR): 68 patients with normoalbuminuria (UACR <30 mg/gCr), 31 patients with microalbuminuria (30 mg/gCr ≤ UACR < 300 mg/gCr), and 17 patients with macroalbuminuria (UACR ³300 mg/gCr). Progression of albuminuria was the main outcome. Omentin was measured by ELISA, and the values were adjusted for age, BMI, and sex before analysis.

Results: Progression either to the next albuminuria level in 16 patients or to end-stage renal disease (ESRD) occurred in 5 patients. No difference in adiponectin concentrations was observed between progressors and nonprogressors in patients with normoalbuminuria. In the patients with microalbuminuria and macroalbuminuria, progression of albuminuria was associated with higher omentin. Progression to ESRD was also associated with estimated glomerular filtration rate (eGFR). When these covariates were inserted in a Cox regression analysis, eGFR and omentin were significantly associated with progression of albuminuria.

Conclusions: Increased serum omentin levels predict the progression from microalbuminuria to macroalbuminuria and macroalbuminuria to ESRD in diabetic patients.

FR-PO615

The Expressions of Vitamin D and Its Receptor in Patients with Diabetes Associated with Proteinuria and Diabetic Nephropathy Yang Yang, Jia Guo, Zhangsuo Liu. *The Firts Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.*

Background: Vitamin D receptor (VDR) is a member of the nuclear receptor superfamily, and there was no report about the expression of Vitamin D and its receptor in patients with diabetes associated with proteinuria and diabetic nephropathy. So, this study aimed to test the expression trends of VDR in blood, urine specimens and renal tissues of diabetic nephropathy, and the relationship with urinary protein, to explore the role of VDR in diabetic nephropathy.

Methods: 1. 65 patients who had been diagnosed with T2DM (with or without albuminuria) were enrolled in this study and 25 healthy control subjects were enrolled (NC group).The patients were classified according to the ratio of urinary excretion of albumin/creatinine (ACR). Diabetic patients without proteinuria (DM group, ACR: less than 30 mg/g, n = 25), with microalbuminuria (DN1 group, ACR: 30 to 300 mg/g, n = 24) and clinical proteinuria (DN2 group, ACR: more than 300 mg/g, n = 18). 25 diabetic nephropathy patients who were diagnosed by renal biopsy (DN3 group). 2. The expressions of VD and VDR in the plasma and urine supernatant were measured by ELISA, and the VDR in blood cells was measured by qRT-PCR, The expressions of VDR in kidney tissue were measured by immunohistochemical staining.

Results: Plasma VD and VDR levels were significantly lower in DN2 and DN3 groups as compared with NC group (plasma VD 0.78±0.24 and 0.88±0.29 vs. 2.32±1.33ng/ml, P<0.05, VDR 157.52±98.36 and 164.20±64.50 vs. 325.33±194.68ng/ml, P<0.05). [circ2] Urinary VD and VDR levels were significantly elevated in DN2 and DN3 groups as compared with NC group (urinary VD 1.34±0.58 and 1.42±0.44 vs. 1.18±0.65ng/ml, P<0.05, VDR 83.60±31.78 and 88.40±28.10 vs. 60.93±12.03ng/ml, P<0.05). The expressions of VDR in kidney tissue in DN groups were obviously lower than those in control groups, differences were statistically significant(P<0.05).

Conclusions: These results verify that VDR declined with the increase of the amount of urine protein . Based on these results, VDR may play a role of renal protection in diabetic nephropathy.

Mitochondrial DNA in the Plasma and Urine: A Potential Biomarker to Predict the Progression of Nephropathy in Type 2 Diabetes Mellitus Li Fang, Junwei Yang. *Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.*

Background: Mitochondrial dysfunction and chronic sterile inflammation are the most common features of type 2 diabetes mellitus. Thus, our objective was to investigate whether extracellular mitochondrial DNA (mtDNA) in the plasma and urine could be used as a biomarker predicating the progression of type 2 diabetes and nephropathy.

Methods: A total of 42 people with type 2 diabetes and 35 ages-, sex- matched people without diabetes were enrolled in this study. The absolute quantification of mtDNA content was measured by real-time polymerase chain reaction. Relationships among different variables were analyzed by general linear model correlation.

Results: The plasma mtDNA contents were significantly lower in the people with type 2 diabetes, particularly in those participants with clinically significant proteinuria. The plasma mtDNA content was negatively correlated with diastolic blood pressure, urine microalbumin and 24-hour urine protein; while positively correlated with platelets count, serum albumin and alkaline phosphatase. The urinary mtDNA contents did not change obviously; however, the creatinine-adjusted values were significantly higher in the group with diabetes. Besides, the urinary mtDNA-to-creatinine ratio was negatively correlated with the duration of diabetes, fasting glucose and glycosylated hemoglobin.

Conclusions: Our results indicated that lower plasma mtDNA content and higher urinary mtDNA-to-creatinine ratio might be the potential biomarkers predicting the progression of nephropathy in type 2 diabetes.

Involvement of Fractalkine and Its Receptor CX3CR1 in Disease Progression of Patients with Diabetic Nephropathy Takahiro Uchida,[1] Takashi Oda,[2] Hidehito Matsubara,[1] Atsushi Watanabe,[1] Hanako Takechi,[1] Toshihiko Imakiire,[1] Naoki Oshima,[1] Hiroo Kumagai.[1] *[1]Dept of Nephrology and Endocrinology, National Defense Medical College, Tokorozawa, Japan; [2]Dept of Nephrology, Tokyo Medical Univ Hachioji Medical Center, Hachioji, Japan.*

Background: Upregulated expression of fractalkine (CX3CL1) and its receptor CX3CR1 has been reported in some renal diseases. However, whether they are involved in human diabetic nephropathy (DN) is unclear. We therefore examined expression of these molecules in human DN.

Methods: Twelve patients with DN who were diagnosed by renal biopsy were studied. Expression of CX3CL1 and CX3CR1$^+$ cells and degree of inflammatory cells were evaluated. Glomerular endothelial cell (GEC) was assessed by measuring the immunofluorescence (IF) intensity of CD34 staining.

Results: Expression of CX3CL1 or CX3CR1 was not observed in normal control tissues. CX3CL1 was expressed on GECs, tubular epithelial cells, and endothelial cells of peritubular capillaries in renal tissues with DN. Expression of CX3CL1 on GECs was found in 9 patients, and its expression was seen with an increase tendency in patients with early stage of DN; CX3CL1 expression was found in all patients with the early stage of DN, whereas its expression was found only in 5 out of 8 patients with the advanced stage. CX3CR1 expression was also upregulated in renal tissues with DN. The majority of the CX3CR1$^+$ cells in glomeruli were GECs; CX3CR1$^+$ inflammatory (CD45$^+$) cells composed only a small number of CX3CR1$^+$ cells in glomeruli, most of which were CD68$^+$ macrophages. Double stainings for CX3CL1 and CD34, and for CX3CR1 and CD34 revealed that both CX3CL1 and CX3CR1 were expressed on GECs with decreased expression for CD34.

Conclusions: These data demonstrate that CX3CL1 and CX3CR1 were upregulated in human DN from early stage. Interestingly, not only CX3CL1 but also CX3CR1 were expressed on GECs, and their expression on GECs may be involved in GEC injury. Targeting CX3CL1 and CX3CR1 may be promising therapeutic approaches for DN.

FR-PO618

Klotho Association with Markers of Mineral Metabolism and Insulin Resistance in Diabetic Patients with Chronic Kidney Disease Ana Paula Silva, Filipa Brito Mendes, Pedro L. Neves. *Nephrology, Centro Hospitalar do Algarve, Faro, Portugal.*

Background: Klotho is a protein implicated in multiple organic processes, being able to regulate growth factors signaling pathways, ion channels and transporters. Several animal and clinical demonstrated that Chronic Kidney Disease (CKD) is associated with Klotho deficiency. Moreover, Klotho seems to play a renoprotective role through its anti-oxidation properties, protection of vasculature, and promotion of vascularization and inhibition of fibrinogenesis. In this study we investigated potential associations between serum Klotho levels and known markers of mineral metabolism and insulin resistance, in order to better understand how Klotho affects/is affected by these variables in diabetic patients with CKD.

Methods: In this study we included 107 type 2 diabetic patients (67 males, 62,6%) with CKD stage 2-3, a mean age of 66.6 ±9.7 years. Several laboratory parameters were assessed: eGFR, phosphorus, vitamin D, PTH, urine albumin/creatinine ratio (UACR), IL-6, FGF-23, OxLDL and the homeostasis model assessment (HOMA). Simple linear and multiple regressions model were used to investigate possible correlations between these variables and Klotho.

Results: In the simple linear model, Klotho levels were correlated with age (r=-0.232,p= 0.016), phosphorus (r=-0.381,p< 0.001), PTH (r=-0.606,p< 0.001), UACR (r= -0.336,p< 0.001), HOMA (r= -0.482, p< 0.001), IL-6 (r= -0.571, p < 0.001), FGF-23 (r=-0.695, p < 0.001), OxLDL (r=-0.598,p < 0.001), eGFR (r=0.228, p = 0.018) and vitamin D (r= 0.661, p < 0.001) levels. Applying the multivariate linear regression, only the UACR (r=-0.636 p= 0.036), HOMA (r=-0.322,p=0.018), FGF-23 (r=-0.668,p < 0.001) and Vitamin D (r=8.465 p=0.010) independently influenced the Klotho levels.

Conclusions: In our study,Klotho levels are influenced by FGF-23, vitamin D and insulin resistance, variables that are affected by the renal function. However, in the multiple regression model the eGFR lost its relationship with Klotho, and Klotho was associated mainly with the UACR and insulin resistance. More studies are needed to clarify of the relationship with UACR and confirm if proteinuria is more critical in the definition of the Klotho levels.

FR-PO619

Macrophage Accumulation and Phenotype in Human Diabetic Nephropathy
Ying Yang, Yinfeng Guo, Zhixia Song, Min Zhou, Xiaoliang Zhang. *Southeast Univ.*

Background: Macrophage, especially its distinct phenotype is involved in the progress of DN. M1 is characterized with pathogenic function, while M2 displays anti-inflammatory. This study tries to examine the macrophage phenotype and its relationship to the renal function and histological changes in human DN.

Methods: We studied retrospectively 46 patients with DN who were confirmed by diagnosis of renal biopsy. Biopsies were divided into I IIa IIb III IV classes according to the pathologic classification of DN. Patients with renal trauma or renal tumor were considered as control group. Serum creatinine, proteinuria were calculated. Kidney tissues were used to assess histological changes and the presence of macrophage marker CD68, M1 marker iNOS, M2 marker CD206, Arg-1, TREM1 and TREM2.

Results: In biopsy renal tissue of human DN, Expression of CD68, M1 were significantly increased in the glomeruli (2.835±1.045/gcs VS 1.203±0.547/gcs for normals P=0.031; 2.330±1.343/gcs VS 0.896±0.548/gcs for normals P=0.046) and interstitium (0.037±0.142%area VS 0.019±0.002%area P= 0.016; 0.018±0.008%area VS 0.009±0.005%area P=0.023). While M2 were mainly observed in the interstitium (0.019±0.008%area VS 0.010±0.004%area P=0.038). Interstitium M2 correlated strongly with interstitium M1 infiltration. Additionally there was a positive correlation between the glomerular CD68, M1 numbers and serum creatinine (r=0.619, p=0.001; r=0.463, p=0.017), proteinuria (r=0.641, P=0.000; r=0.508, P=0.008), mesangical matrix, interstitial collagen deposition. Likewise, the expression of interstitial CD68, M1, M2 also correlated strongly with serum creatinine (r=0.638, P=0.000; r=0.606, P=0.001; r=0.520, P=0.006), proteinuria (r=0.749, P=0.000; r=0.651, P=0.000; r=0.694, P=0.000), mesangical matrix, interstitial collagen deposition. Besides TREM1,2-positive cells were apparent in the interstitium and the expression levels significantly correlated with interstitium M1,M2 expression respectively.

Conclusions: Macrophage infiltration and polarization participate in the development of diabetic nephropathy.

FR-PO620

Risk of Diabetes Increased According to the Level of Urinary Albumin Excretion Even Within Normal Range
Dong-Young Lee,[1] Beom Kim,[1] Kyoung Hyoub Moon,[1] Sung Keun Park,[2] Younjoo Jung.[1] *[1]Internal Medicine, VHS Medical Center, Seoul, Republic of Korea; [2]Total Heath Care Center, Kangbuk Samsung Hospital, Sungkyunkwan Univ, School of Medicine, Seoul, Republic of Korea.*

Background: Urine albumin creatinine ratio (UACR) as a reliable index of urinary albumin excretion is getting great attention on its predictive role for various diseases related with diabetes. Nevertheless, predictive value of UACR within normal range was not clarified for diabets yet. Therefore, this study was aimed at examining the clinical association between normal range of UACR and development of diabetes.

Methods: We identified 1,274 non-diabetic Korean men within normal range of UACR in 2005, and followed them up until 2010. All subjects were classified into three categories with respect to baseline UACR, from the lowest to the highest. The incidence rates of diabetes were compared according to the tertile groups of UACR, and the independent hazard ratios (HRs) of UACR levels for diabetes was measured by Cox proportional hazards analysis.

Results: During follow-up, diabetes developed in 97 out of 1,274 subjects (7.6%). Incidence rate of diabetes increased in proportion to the levels of UACR (tertile 1; 4.9%, tertile 2; 7.3%, tertile 3; 10.6%, p<0.001).

	UACR		
	Tertile 1(<3.17)	Tertile 2 (3.17≤, <4.95)	Tertile 3 (≥4.95)
Age (year)	49.5	52.6	53.9
SBP (mmHg)	113.9	114.6	119.9
DBP (mmHg)	77.0	78.3	81.4
FBS (mg/dL)	96.5	98.5	99.8
HOMA-IR	1.83	1.91	2.07
HbA1C (%)	5.3	5.4	5.4
sCr (mg/dL)	1.16	1.11	1.12
Hypertension (%)	19,8	23.7	37.5
Development of diabetes (%)	4.9	7.3	10.6

table1. Baseline characteristics of participants according to tertile groups of UACR levels (N=1,274)
All variable are shown by mean value. P-value were ≤0.001 except development of diabetes (P=0.002)

The subjects with incident diabetes had the higher normal range of UACR than those without incident diabetes (5.3±4.2 μg/mg and 6.7±4.2 μg/mg, p=0.013). When tertile 1 was considered as reference, HRs for diabetes was higher in tertile 3 (2.06; 1.16-3.37), even after adjusting for age, BMI, total cholesterol, log(HOMA-IR) and eGFR.

Conclusions: Elevated UACR, even within normal range, was significantly associated with the future development of diabetes.

FR-PO621

Albuminuria Is Positively Associated with Elevated Numbers of Circulating Endothelial Pre- and Mature Cells, but Inversely Associated with Circulating Fibrocytes
Tine Hansen,[1] Bernt Johan Illum von Scholten,[1] Alexander Rosendahl,[2] Regine Bergholdt,[2] Peter Rossing.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Novo Nordisk A/S, Måløv, Denmark.*

Background: Diabetic nephropathy is characterized as a microvascular disease with enhanced vascular leakiness in the kidney and aberrant tissue remodelling. Abnormal number and function of endothelial cells, stem cells and activation of leukocytes is considered as contributing mechanisms to the "kidney-micro"-vascular leaky syndrome. We determined if circulating endothelial pre- and mature cells, fibrocytes or monocyte sub-populations were abnormally regulated in type 2 diabetic patients with albuminuria.

Methods: Cross-sectional study of 37 type 2 diabetic patients; 18 with normoalbuminuria (<30mg/24h) and 19 with albuminuria (³30mg/24h). 8-color flow cytometry analysis of peripheral blood was performed. ANCOVA compared expression of cell markers and absolute number of specific cell populations in patients with normoalbuminuria *vs*. albuminuria.

Results: Expression of VEGFR2 was significantly enhanced in patients with albuminuria (p=0.009). Also, the total number of circulating mature endothelial cells (CEC) was significantly enhanced in albuminuria (p<0.001). Circulating fibrocyte number and collagen-1 expression was inversely associated with albuminuria (p£0.037) and TGFbeta stabilizing and M2-associated galectin-3 expression on M1-like and M0-like monocytes was positively associated with albuminuria (p£0.029). In contrast, expression of the M1-associated marker CD11c (p=0.042) was inversely associated with albuminuria on all monocytes, particularly on M0-like macrophages (p=0.014).

Conclusions: The enhanced number of CEC together with elevated expression of VEGFR2 may indicate an aberrant function of the CEC with reduced capacity to heal the kidney microvascular disease. The imbalanced M2-polarization of monocytes and aberrant fibrocyte count may favour improper repair leading to excessive tissue fibrosis. Hence therapeutic approaches addressing migratory pattern of CEC, providing adjuvant activating signals or restoring the immune balance might provide novel individualized treatment regimes.

FR-PO622

Prognostic Value of Tubulointerstitial Lesions and Urinary N-Acetyl-β-D-Glucosaminidase in Patients with Type 2 Diabetes and Biopsy-Proven Diabetic Nephropathy
Koki Mise,[1] Junichi Hoshino,[1] Toshiharu Ueno,[1] Masayuki Yamanouchi,[1] Noriko Hayami,[1] Tatsuya Suwabe,[1] Kenmei Takaichi,[2] Yoshifumi Ubara.[1] *[1]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Kanagawa, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: Recently, it has been reported that some biomarkers of renal tubular injury are useful to predict the renal prognosis in the early stage of diabetic nephropathy (DN). However, how closely such biomarkers reflect actual tubulointerstitial damage remains unknown.

Methods: Among 210 patients with type 2 diabetes and biopsy-proven DN, 152 patients were enrolled, 89% of whom had overt proteinuria. The endpoint was defined as a 50% or more decrease of the estimated glomerular filtration rate (eGFR) from baseline or commencement of dialysis due to end-stage renal disease. The Cox proportional hazard model was used to calculate the hazard ratio (HR) and 95% confidence interval (CI) for the death-censored endpoint.

Results: A significant correlation was found between baseline urinary N-acetyl-β-D-glucosaminidase (NAG) excretion and the score for interstitial fibrosis and tubular atrophy (IFTA score) (r=0.39, P<0.001). The influence of urinary NAG on the renal prognosis was attenuated after adjustment for known promoters of progression (+1SD for log NAG, HR: 0.87 [95% CI: 0.66-1.13]). On the other hand, the IFTA score was significantly related to the outcome even after adjustment for those covariates (+1 for IFTA score, HR: 2.20 [1.50-3.21]).

Conclusions: The assessment of urinary NAG excretion did not improve the prognostic power of known indicators of progression, whereas the IFTA score did. The IFTA score may be more useful for predicting the renal prognosis than current tubulointerstitial markers, especially in patients with advanced DN.

FR-PO623

Is There Any Benefit of Performing Renal Biopsies in Patients with Diabetic Nephropathy when No Other Diagnosis Than Diabetic Nephropathy Is Found? Rosa M. Montero,[1] Dimitrios Anestis Moutzouris,[1] Ranmith Perera,[2] David Goldsmith.[1] *[1]Nephrology & Transplantation, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom; [2]Histopathology, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom.*

Background: The risk of renal biopsy has long been thought to outweigh the benefit of performing these on patients with diabetes mellitus (DM) leading to small numbers of renal biopsies in this population. Those biopsied have a propensity to more proteinuria or haematuria precipitating biospy. Glomerular lesions alone have long been the hallmark of diabetic nephropathy (DN) however looking back at the biopsy can there be more to see?

Methods: All native renal biopsies diagnosed with DN from 2009-2014 were retrieved from archive at Guy's & St Thomas' NHS foundation trust. Renal biopsies were performed in patients with DM who had heavy proteinuria or haematuria on presentation. Biopsies with a DN diagnosis alone were identified and Tervaert's new DN classification was applied. Clinical outcome data was collected from electronic patient records. Cox regression models were used to perform statistical analysis.

Results: 3000 native kidney biopsies were performed from 2009-2014. 34 DM patients had DN alone on renal biopsy, 12 T1DM and 22 T2DM. 20 male, 14 females.Ethnicity:35% white, 35% black, 3% asian, 27% other. Age range:24-86 years (median 55). UPCR 13-1492 mg protein/mmol creatinine (median 392) eGFR 7-74.9 (median 23). 8.8% 5 year mortality. Glomerular IV and Interstitial fibrosis III lesions were significant predictors of renal survival (p=0.013 HR 27.5, p=0.006 HR 21.3, respectively). Renal survival ranged from 1-60 months post renal biopsy (median 3).

Conclusions: Interstitial fibrotic lesions are as important as glomerular lesions in predicting renal survival. Determining the significance of the compartments in predicting outcome may be more sensitive; however few biopsies are undertaken in this population. The role of an earlier renal biopsy showing less well established features in the DN population that could be reversed may need us to review our practice unless sensitive and specific biomarkers are found to correlate with the underlying histopathology.

FR-PO624

Understanding the Relationship Between Histopathology and Renal Function in Hypertension and Diabetes Matthew Palmer,[1] Jordana B. Cohen,[2] Mendy Liang,[2] Steven S. Pullen,[3] Katalin Susztak.[2] *[1]Pathology, Univ of Pennsylvania, Philadelphia, PA; [2]Nephrology, Univ of Pennsylvania, Philadelphia, PA; [3]CardioMetabolic Research, Boehringer Ingelheim, Ridgefield, CT.*

Background: Much of the literature relating clinical and pathologic variables in patients with diabetes mellitus (DM) and hypertension (HTN) has relied on biopsy series. To gain unbiased insight into the degree of interstitial fibrosis (IF) and glomerular sclerosis (GS) associated with decline of renal function in DM and HTN, we have correlated histopathology with renal function, DM and HTN status in patients undergoing tumor nephrectomies.

Methods: Data and renal tissue were collected on nephrectomy patients from 7 centers. We used Spearman correlation coefficients to compare eGFR with pathologic assessment of IF (estimate) and GS (manual count). Bivariate linear regression was used to assess the association between log-transformed percent IF or GS and eGFR, stratifying by presence of DM or HTN.

Results: Of 251 patients, there were 60 without DM or HTN, 89 with HTN alone, and 102 with DM (+/- HTN). Median age was 62, 42% were female, 60% were Caucasian, median systolic blood pressure was 134 mmHg, and median eGFR was 66.5. There was a significant association between decline in eGFR and both IF (rho=-0.50, p<0.01) and GS (rho=-0.53, p<0.01). eGFR of 60 was associated with a geometric mean (95% CI) IF and GS of 7.3% (5.1-10.3) and 8.3% (5.7-12.1) for patients without DM or HTN, 9.2% (7.5-11.2) and 8.7% (7.0-10.8) for patients with HTN, and 10.9% (8.8-13.5) and 9.6% (8.0-11.6) for patients with DM. Stage 3 CKD was associated with a median IF and GS of 10% (IQR 5-15) and 11.3% (IQR 5.7-18.8) overall, and with median IF and GS of 10% (IQR 5-20) and 11.9% (IQR 5.7-20.8) in DM.

Conclusions: While IF and GS are similar at a given eGFR, patients with DM have a trend toward a greater degree of IF and GS at the same level of eGFR compared to those with isolated HTN. Stage 3 CKD is associated with median IF of 10% though there is high individual variation. This highly variable histopathology should be considered when patients with DM are included into clinical studies, and kidney biopsies might be useful to include in categorization.

FR-PO625

Efferent Arterioles Are Special Target for Obesity Noriko Uesugi, Michio Nagata. *Kidney and Vascular Pathology, Faculty of Medicine, Tsukuba Univ, Tsukuba, Ibaraki, Japan.*

Background: The link between obesity and renal disease is unclear. Hyperfiltration is suspected to induce arteriolar hyalinosis and glomerular hypertrophy in moderate to severe obesity. To assess morphological changes in mild obesity, we investigate human non-tumor renal tissue from 7 mild obese cases (Ob)(BMI 27)(Age 61y.o, S-Cre 0.8md/dl. 4 with hypertension) and compared with 7 hypertensive case (HT) and 4 control(Con).

Methods: Total 150 of serially cut paraffin sections were double immunostained with CD34 as endothelial marker, and smooth muscle actin as medial marker, followed by PAS stain. Incidence of hyalinosis in afferent and efferent arterioles, intraglomerular cystic dilatation connecting to efferent arterioles, segmental sclerosis, sclerotic glomeruli(GS) and average size of glomeruli were assessed using 30-40 glomeruli per case.

Results: The morphological data were as follows; average glomerular diameter 203±26*, 181±19, 156±4 um, incidence of afferent arteriolar hyalinosis 43±13*,47±29*, 20±16 % and that of efferent arterioles, 30±10**, 13±14, 5±4% for Ob, HT and Con, respectively (*P<0.05 vs Con, **P<0.05 vs Con and HT). Higher incidence of cystic dilatation near efferent arterioles was noticed in Ob (21±15%) than HT and Con (2±15, 0%, respectively)(P<0.05).Obese cases revealed neither significant intimal thickening nor distortion in the interlobular arteries, no segmental sclerosis, low incidence of GS (11±7%) and minimal interstitial damage(<10%.).

Conclusions: Efferent arterioles are targets for obesity, which suggest that specific mechanism of glomerular hyperfiltration involves obese cases, even in mild form.

FR-PO626

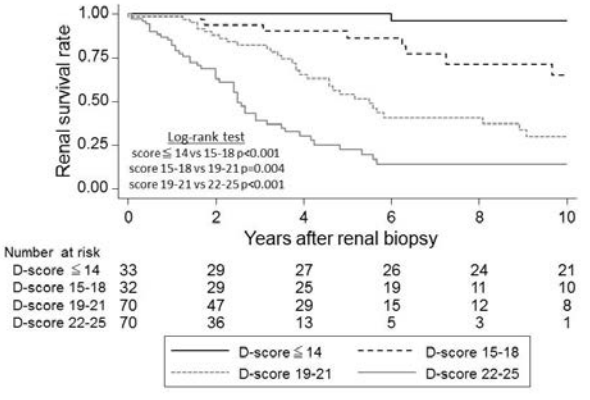
A Pathological Scoring System to Predict Renal Outcome in Diabetic Nephropathy Junichi Hoshino, Koki Mise, Toshiharu Ueno, Keiichi Sumida, Masayuki Yamanouchi, Noriko Hayami, Tatsuya Suwabe, Shigeko Hara, Yoshifumi Ubara, Kenmei Takaichi. *Nephrology Center, Toranomon Hospital, Tokyo, Japan.*

Background: With association between diabetic nephropathy (DN) and renal outcome increasingly clear, we aimed to create a new DN pathological scoring system that could predict renal outcome.

Methods: We studied 205 patients with DN confirmed by renal biopsy between March 1985 and January 2010 who met inclusion criteria. Renal biopsy included clinical parameters and Tervaert classifications. Hazard ratios (HRs) for end-stage renal disease (ESRD) were estimated by adjusted Cox regression. Overall pathological risk score (D-score) was calculated by summing the products of beta-coefficient and bootstrap-inclusion fractions, its predictive utility evaluated by Kaplan-Meier methods and c-statistics with 10-fold cross-validation for 10-year risk of ESRD.

Results: D-scores of glomerular classes 1, 2A, 2B, 3, and 4 were, respectively, 0, 3, 4, 6, and 6. Those of interstitial fibrosis and tubular atrophy classes 0, 1, 2, and 3 were 0, 7, 9, and 11, and those of interstitial inflammation classes 0, 1, and 2, respectively, 0, 3, and 4. D-score of hyalinosis class 2 was 3, and that of arteriosclerosis class 2 was 1. So a patient's D-score could be 0-25.

Figure 1



HRs for ESRD in patients with D-score£14, 15-18, 19-21, and 22-25 were, respectively, 1.00 (ref.) 16.21 (1.86-140.90), 19.78 (2.15-182.40), and 45.46 (4.63-446.68) after adjusting for clinical factors. When comparing c-statistics, a model that included D-score in addition to age, eGFR, and proteinuria, showed a slight improvement from 0.901 (0.861-0.942) to 0.932 (0.898-0.965). The net reclassification index also showed better reclassification (0.24 (-0.02 to 0.49)).

Conclusions: In addition to clinical parameters, D-score may have improved prediction of 10-year risk of ESRD. Patients with D-score £14 had excellent renal prognosis.

FR-PO627

Hyperphosphatemia and Tubulointerstitial Injury in the Progression of Diabetic Nephropathy Song Jiang, Yu Pan, Dandan Qiu, Yu An, Hao Chen, Yongchun Ge, Honglang Xie, Zhihong Liu. *National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.*

Background: Our aim was to evaluate the relationship between tubulointerstital injury and hyperphosphatemia in the patients with type 2 diabetes and diabetic nephropathy (T2DN), and investigate the association of hyperphosphatemia with the renal outcome, especially in the T2DN patients with eGFR≥60 ml/min per 1.73m^2.

Methods: A total of 396 patients with T2D and biopsy-proven DN from Nanjing DN registration system who received follow-up for at least 1 year were recruited and median 5-year follow-up. Renal outcomes were defined by progression to end-stage renal disease and doubling of serum creatinine.

Results: Of the participants, the mean baseline eGFR was 73.86±33.52mL/min per 1.73 m^2. The levels of the urinary tubulointerstitial injury markers including the NAG, RBP and NAGL were significantly difference among quintiles of serum phosphorus (P<0.01). The participants whose eGFR≥90 ml/min per 1.73 m^2 had a higher rate of tubulointerstitial injury (interstitial fibrosis tubular atrophy scores of 2 and 3, *P*=0.005; interstitial inflammation scores of 1 and 2, *P*=0.035) in hyperphosphatemia (>1.45 mmol/L) group than in lower phosphorus group (<1.17 mmol/L). Participants with baseline levels of serum phosphorus in higher quintiles had a higher cumulative incidence of ESRD (log-rank, *P*<0.01). In the analyses adjusted by age, sex, diabetes status, BP, FBG, BMI, proteinuria, cholesterol, and eGFR, the relationship between higher serum phosphorus and an increased risk of ESRD remained. The association between serum phosphorus and ESRD risk persisted and was stronger when the sample was restricted to those with a baseline eGFR equal to 60-90 mL/min per 1.73 m^2, but not when it was restricted to patients with a baseline eGFR of 30-60 mL/min per 1.73 m^2.

Conclusions: These findings indicated the baseline serum phosphorus is associated with tubularinterstitial injury of T2DN patients. And serum phosphorus >1.45mmol/L is an independent risk factor of ESRD in T2DN, especially in the patients with eGFR≥60 ml/min per 1.73m^2.

Longitudinal Changes in Estimated Glomerular Filtration Rate in Youth with Type I Diabetes Katherine D. Westreich,[1,2] Nora Fino,[1,3] Maryam Afkarian,[1,4] David M. Maahs,[1,5] Amy K. Mottl.[1,2] *[1]for the SEARCH for Diabetes in Youth Study; [2]Univ of North Carolina; [3]Wake Forest School of Medicine; [4]Univ of Washington; [5]Univ of Colorado Denver.*

Background: Diabetes is the leading cause of kidney disease in the US. The natural history of kidney function early in type I diabetes (T1D) is relatively unknown.

Methods: SEARCH for Diabetes in Youth is a multicenter cohort study of incident diabetes in youth <20 yrs at diagnosis. Cystatin C (CysC) was measured at two study visits; values were calibrated for assay drift and standardized to the reference material. GFR was estimated using the CysC-based Filler equation, the only pediatric equation validated in hyperfiltration. Participants were stratified by change in eGFR: gain of >3ml/min/1.73m^2/yr, loss of >3ml/min/m^2/yr, or stable. Nominal multinomial regression was used to predict eGFR outcome category. Covariates included gender, race/ethnicity, and follow up age, fasting glucose, HbA1c, insulin sensitivity score, renin-angiotensin inhibition, and systolic blood pressure Z-score (SBPZ).

Results: The analysis included 905 participants with T1D (mean age 14 ±4 yrs; duration 4.2 ±1.9 yrs, HbA1c 8.7% ±1.8%; SBPZ -0.3 ±1.0 and CysC 0.73 ±0.12 mg/L). Follow up CysC was measured 4.6 ±1.3 yrs later. 323 (36%) participants lost eGFR (mean 150+30 fell to 119+23, p<0.0001); 197 (22%) gained eGFR (mean 122+22 rose to 151+29, p<0.0001) and 385 (42%) had stable eGFR. Odds ratios (OR) for predictor variables significant in any pairwise comparison are shown below.

Variable	OR (95%CI) eGFR loss vs stable (ref)	OR (95% CI) eGFR gain vs stable (ref)	OR (95% CI) eGFR loss vs gain (ref)
N	323 vs 385	197 vs 385	323 vs 197
Age (per 1 year)	0.92 (0.88-0.97)	1.07 (1.00-1.14)	0.87 (0.81-0.93)
Female gender	NS	1.64 (1.14-2.38)	0.59 (0.40-0.88)
SBP Z-score (per 1 point)	1.16 (1.03-1.30)	1.15 (1.00-1.33)	1.36 (1.17-1.59)
Fasting glucose (per 100mg/dl)	NS	1.22 (1.01-1.30)	0.80 (0.66-0.98)
HbA1c (per 1%)	NS	1.15 (1.01-1.29)	NS

Conclusions: Changes in eGFR are heterogeneous early in T1D and are predicted in part by SBPZ, age, gender, glucose and HbA1c. Continued follow up will determine whether early changes in eGFR may identify those at risk for subsequent kidney disease.

FR-PO629

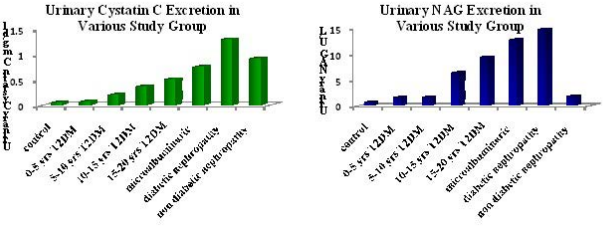
A Cross-Sectional Study for Evaluating the Diagnostic Accuracy of Cystatin C and N-Acetyl β-D Glucosaminidase in Predicting Diabetic Nephropathy Dhara Nrupal Patel, Kiran Kalia. *BRD School of Biosciences, Sardar Patel Univ, Anand, Gujarat, India.*

Background: Diabetic nephropathy (DN) is classified into V stages. Amongst which, stage I-II are reversible proximal tubule damage stages, and III- V are well established irreversible glomerular damage stages. The inability of creatinine and microalbuminuria to detect early reversible stages urges the necessity of new efficient diagnostic biomarkers. Thus, we have selected proximal tubule originated proteins; cystatin c (cyst c) and N-acetyl β-D Glucosaminidase (NAG) to study their efficacy in detecting early manifestations of DN.

Methods: Urinary/serum cyst c and NAG were estimated in total 491 age-matched patients enrolled for our cross-sectional study. Their efficacy was compared with urinary microalbuminuria, serum creatinine and eGFR in patients with varying type 2 diabetes (T2DM) duration and various stages of DN.

Results: Patients with 5-10 yrs of T2DM duration showed a significant increase in cyst c level while urinary NAG increased in T2DM patients with 10-15 yrs of diabetic duration. The ROC curve signifies diagnostic efficacy of urinary cyst c (AUC 0.820) over urinary NAG (AUC 0.678), in detecting T2DM patients susceptible to develop DN.

Figure 1: Comparison of urinary Cystatin c and NAG in various groups



Conclusions: Urinary cyst c in comparison to urinary NAG plays a significant role in predicting the early renal decline in T2DM patients with varying duration of diabetes. Furthermore, the presence of such low molecular weight protein and renal origin enzyme indicates pathogenesis of proximal tubule in early stages of DN.

FR-PO630

The Relationship Between Diabetic Retinopathy and Diabetic Kidney Disease in a Population-Based Study in Korea (KNHANES V2-3) MinJeong Lee,[1] Won june Lee,[2] Seirhan Kim,[1] Gyu Tae Shin,[1] Heungsoo Kim.[1] *[1]Dept of Nephrology, Ajou Univ School of Medicine, Suwon, Republic of Korea; [2]Dept of Opthalmology, 102 Replacement Depot, Republic of Korea Army, Chuncheon, Republic of Korea.*

Background: Previous studies of the association between diabetic kidney disease (DKD) and diabetic retinopathy (DR) used only albuminuria/proteinuria as chronic kidney disease (CKD) markers and, hence, did not consider eGFR. This study aimed to evaluate the prevalence of DKD and the association between DKD, as evaluated by both proteinuria and eGFR, and DR in the large cohort of patients with type 2 diabetes from the Korea National Health and Nutrition Examination Survey (KNHANES V).

Methods: From the fifth (2011, 2012) KNHANES, 971 participants with type 2 diabetes were included. Selected samples were weighted to represent the entire civilian population in Korea. DKD was defined as diabetes with the presence of albuminuria and/or impaired GFR. Nonproteinuric DKD was defined as estimated glomerular filtration rate (eGFR) calculated by Modification of Diet in Renal Disease (MDRD) equation < 60 ml/min/1.73m^2 and no albuminuria. Multivariate logistic regression analysis was performed to determine risk factors, including DR, associated with DN in the Korean population.

Results: Among the 971 DM patients, the prevalence of microalbuminuria was 19.3 % and that of macroalbumununia was 5.5 %. The prevalence of eGFR < 60ml/min/1.73m2 was 9.1%, and half of those were nonproteinuric DKD. We observed a prevalence of 20.0% for DR and 3.8% for Proliferative DR(PDR). Multiple logistic regression analysis revealed that HTN [aOR = 1.75; 95% CI = 1.19 – 2.59], HbA1c[aOR = 1.24; 95% CI = 1.12 - 1.39], and PDR[aOR=2.80; 95% CI = 1.32 – 5.96] were independent factors correlated with proteinuric DKD, and the older age [adjusted odds ratio (aOR) = 1.19; 95% confidence interval (CI) = 1.09 – 1.31] and the presence of hypertension [aOR = 5.50; 95% CI = 1.37 – 22.71] were significantly associated with nonproteinuric DKD.

Conclusions: Nonproteinuric renal dysfunction in type 2 DM is not rare. PDR is associated with proteinuric DKD, however, DR and PDR are not significantly associated with nonproteinuric DKD.

FR-PO631

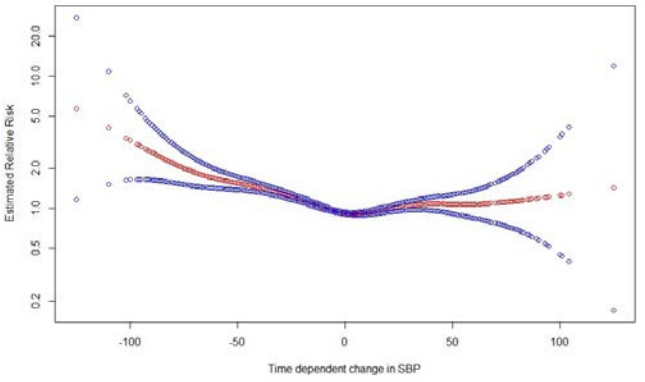
A Decrease in Blood Pressure During Follow-Up Is Associated with an Increased Risk of All-Cause Mortality in Patients with Type 2-Diabetes and Renal Impairment – The Swedish National Diabetes Register (NDR) Hanri Afghahi,[1] Stefan Franzén,[2] Ann-marie Svensson,[2] Bjorn Eliasson,[3] Maria Svensson.[3] *[1]Nephrology, Skaraborg Hospital, Skövde, Sweden; [2]Center of Registers, Gothenburg, Sweden; [3]Medicine, Sahlgrenska Univ Hospital, Gothenburg, Sweden.*

Background: A U-shaped relationship between systolic blood pressure (SBP) and risk of all-cause of mortality has been found in patients with type 2 diabetes (T2D) and renal impairment (RI). We here assess the association between time-dependent mean SBP, change in SBP during follow up and risk of all-cause mortality.

Methods: 27 732 patients with T2D and RI (eGFR<60ml/min/1.73m^2 MDRD) classified into 10 mmHg intervals according to SBP at baseline were followed for 4.7 years. The risk of all-cause mortality was estimated using time-dependent mean SBP and change in SBP from last observation by time-dependent adjusted cox model. A smoothing spline describe the influence of mean SBP and the change in SBP on the hazard function.

Results: During follow-up 8265 deaths occurred. Using SBP 130-139 mmHg as a reference group a time-dependent mean SBP <130 mmHg was associated with increased risk of all-cause mortality in all (HR 1.28, 95% CI 1.20, 1.36) and in patients without

previous congestive heart failure (n=23 799) (HR 1.26, 95% CI 1.17, 1.36). In addition, a 25-50 mmHg decrease in SBP from the last observation was associated with an increase in risk of all-cause mortality (HR 1.44, 95% CI 1.33, 1.56) compared to a change in the range -10 to 10 mmHg.



Conclusions: A systolic blood pressure < 130 mmHg and a decrease in systolic blood pressure during follow up with or without previous congestive heart failure, is associated with an increase the risk of all-cause mortality in patients with type 2-diabetes and renal impairment.Intensity of hypertensive medication and co-morbidities are important confunders and will be further evaluated.

FR-PO632

Increased Expression of WNT5a in Renal Tubules Is Associated with Diabetic Nephropathy in Humans Malik Asad Anjum,[1] An Xiao,[1] Dean Troyer,[1,2] Michael J. Solhaug,[1] Anca Dobrian,[1] Jerry L. Nadler,[1] Liwei Huang.[1] *[1]Internal Medicine, Eastern VIrginia Medical School, Norfolk, VA; [2]Pathology, Sentara Norfolk General Hospital, Norfolk, VA.*

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease worldwide. In recent years, convincing data has come forward suggesting that inflammatory pathways play a pivotal role in the pathogenesis and progression of DN. Identification of these inflammatory pathways and associated biomarkers may help in the early diagnosis of DN and development of novel targeted therapeutic strategies to help prevent, treat and even slow the progression of DN. Wnt5a, a secreted glycoproteins, plays an important role in normal kidney development and is also a pro-inflammatory factor which has been associated with renal fibrosis and disruption of matrix metabolism. The objective of our study was to investigate the expression of WNT5a in diabetic kidneys in humans.

Methods: 11 subjects with biopsy confirmed DN were included in our experimental group. Normal kidney tissues from non-diabetic subjects who underwent nephrectomy for renal cell carcinoma were used as controls. Exclusion criteria for the experimental group were HIV positivity, chronic/acute inflammatory diseases (including hepatitis C) and steroids/immunosuppressant medication. WNT5a expression was evaluated in paraffin embedded tissues.

Results: Immunohistochemical analysis of WNT5a expression showed positive staining on the apical side of the plasma membrane of the renal tubular epithelial cells in control kidney tissues. The intensity of the staining is increased in patients with DN compared to normal kidney control tissues. In patients with DN, WNT5a expression is localized both in the cytoplasm and on the apical side of the plasma membrane of the renal tubular cells. WNT5a is also expressed on glomerular cells, but there are no differences in Wnt5a expression between the tissues from diabetic subjects and controls.

Conclusions: Our results suggest that WNT5a expression in renal tubules might have a pathogenic role in the development of human renal tubular fibrosis. These studies are the first to demonstrate an increase in WNT5a expression in renal tubules in DN.

FR-PO633

Accuracy of Serum Creatinine and Glomerular Filtration Rate Estimation for Adjusting Metformin Prescription in European Type 2 Diabetics Olivier Moranne,[1] Coraline Fafin,[1] Pierre Delanaye,[2] Martin Flamant.[3] *[1]Nephrology, CHU, Nice, France; [2]Nephrology, Hospital, Liege, Belgium; [3]Physiology, APHP, Paris, France.*

Background: There is a debate in the literature about the thresholds of serum creatinine (Scr) above which the drug is contraindicated (1.5 mg/dL in men & ³1.4mg/dL in women). For KDIGO, recommendation is a dose-adjustment between 45 and 30mL/min and a withdrawal below 30mL/min. However, in DM2, estimation of renal function based on Scr alone or on eGFR may vary from the true renal function (mGFR). The purpose of our study was to define the performance of the GFR assessment method (Scr or eGFR calculated with Cockcroft-Gault (CG) or CKD-EPI) in terms of metformin dose adjustment in DM2 who underwent a GFR measurement.

Methods: In 243 DM2 patients, GFR was measured by urinary clearance of ^{51}CrEDTA. Non indexed GFR was used. We analyzed the agreement between classification of patients based on mGFR and, first, Scr alone with a cutoff value of 1.5mg/dL in men and 1.4mg/dL in women, second, on eGFR with threshold values of 45 ou 30mL/min. When both methods classified the patient in the same subgroup, the data were considered concordant otherwise overprescription (underprescription) was defined for discordance according to mGFR.

Results: Age was 61 ± 12 y/o, median mGFR was 42 [30-61] mL/min. Based on mGFR , the distribution of the patients according the following GFR class: [90-45] 110(45%), [44-30] 74(30%), < 30: 59(24). In patients with a Scr above the cutoff value, mGFR(mL/min) was <30 mL/min in respectively 23/40 women and 33/106 men. With a threshold of 45mL/min then 30 mL/min, concordance was found in 80/85% then 88/88% of the patients for the CG and CKD-EPI. With a threshold of 30 mL/min, discordance was an overestimation [or underestimation] in 22(9%) and 19(8%) [or 14(6%) and 11(5%)] of the patients with the CG and CKD-EPI.

Conclusions: In this population creatinine-derived equations outperformed Scr alone in correctly classifying the patients in prescription subgroups. However, even with creatinine-based equations, discordance with mGFR occurs in 12-20% of the patients. New strategies such as drug concentration monitoring may be necessary to improve appropriate prescription of metformin in DM2.

FR-PO634

The Association Between Changes in Albuminuria and Clinical Outcomes in the ADVANCE (Action in Diabetes and Vascular Disease: PreterAx and DiamicroN MR Controlled Evaluation) Trial Min Jun,[1,2] Vlado Perkovic,[1] Mark Woodward,[1] Hiddo Jan Lambers Heerspink,[3] Tanvir Chowdhury Turin,[2] John P. Chalmers,[1] Meg J. Jardine,[1] Braden J. Manns,[2] Marcello Tonelli,[1] Brenda Hemmelgarn.[2] *[1]George Inst; [2]U/Calgary; [3]U/Groningen.*

Background: Change in albuminuria may have useful prognostic value. We sought to assess the association between change in urine albumin-to-creatinine ratio(UACR) and the risk of all-cause death, cardiovascular disease(CVD), and end-stage renal disease(ESRD) in the ADVANCE trial.

Methods: We defined UACR change(baseline to 2 years) as ³30% decrease, <30% decrease to <30% increase(minor change; reference), and ³30% increase. Follow-up for outcome ascertainment commenced at the second UACR measurement. We used Cox regression to estimate the hazard ratio(HR), after adjustment for demographics, ADVANCE randomized treatment assignments, comorbidities, laboratory measurements(including baseline UACR), and drug use.

Results: From baseline to 2 years, 34% of 9195 patients experienced a UACR decrease of ³30%, 26% experienced a minor change, and 40% experienced an increase of ³30%. Over the next 2.9 years(median), 520 deaths, 524 CVD events, and 12 ESRD events were recorded. An increase of ³30% in UACR was associated with 50% higher mortality when compared to a minor change ([Figure 1] HR 1.50, 95%CI:1.18-1.90). Increase in UACR was not associated with increased CVD or ESRD, although the direction of effect was similar. A ³30% UACR decrease was not significantly associated with the risk of death or CVD when compared to those with minor change but was significantly associated with lower ESRD risk(HR 0.10, 95%CI:0.01-0.79).

Change in UACR	HR (95% CI)	P-value	P-value for trend
All-cause mortality			
Decrease ≥30%	0.92 (0.71 - 1.19)	0.551	
Minor change (<30% decrease to <30% increase)	Reference	-	<0.001
Increase ≥30%	1.50 (1.18 - 1.90)	0.001	
Cardiovascular disease			
Decrease ≥30%	0.87 (0.69 - 1.11)	0.295	
Minor change (<30% decrease to <30% increase)	Reference	-	0.015
Increase ≥30%	1.16 (0.92 - 1.45)	0.194	
End-stage renal disease			
Decrease ≥30%	0.10 (0.01 - 0.79)	0.029	
Minor change (<30% decrease to <30% increase)	Reference	-	0.011
Increase ≥30%	1.47 (0.34 - 6.24)	0.601	

Conclusions: In type-2 diabetes patients, ³30% increase in albuminuria predicted higher mortality while ³30% decrease was associated with decreased ESRD risk. Our results suggest change in albuminuria may be a potential prognostic marker for clinical outcomes in type-2 diabetes.

FR-PO635

Changes in Glycaemia During Haemodialysis (HD) Are Not Associated with Changes in QTc Interval in Insulin-Treated Diabetic Patients Naveen H. Siddaramaiah,[1] Didem Tez,[1] Thanh Phan,[1] Nicholas J. Linker,[1] Mary Bilous,[1] Sue Winship,[1] Sally M. Marshall,[2] Rudolf W. Bilous.[1] *[1]The James Cook Univ Hospital, Middlesbrough, United Kingdom; [2]Newcastle Univ, Newcastle upon Tyne, United Kingdom.*

Background: QTc prolongation is a risk factor for cardiac arrhythmias, which can lead to sudden cardiac death (SCD). Risk of SCD is higher in the 24hour period before and after the first dialysis of the week perhaps due to greater shifts in electrolyte levels but the impact of changes in glycaemia is not known. **Aim** : To explore the effect of changes in glycaemia and electrolyte levels during HD on QTc interval in C-peptide negative insulin treated diabetic patients.

Methods: 15 diabetic (mean age 54.6yrs) and 5 non-diabetic (mean age 59.6yrs) patients on HD, underwent Holter and continuous glucose monitoring for a week. Blood sampling and 12 lead ECGs were done at the beginning, middle and end of 3 HD sessions. Standard dialysate (5mM glucose) was used. QTc interval was measured taking the mean of 3 consecutive normal QRS complexes.

Results: QTc interval was prolonged significantly at the end of HD in all sessions ($p<0.001$). Change in glucose level (mean±SD -1.8±4.2 vs -1.7± 3.0) did not have a significant effect on the change in QTc interval ($p=0.396$), which was not different in diabetic subjects compared to non-diabetic group ($p=0.390$). Serum K^+, Mg^{2+} and Ca^{2+} levels dropped significantly ($p<0.001$) during all 3 HD sessions. There was no significant difference in the starting level and the drop in K^+, Mg^{2+} and Ca^{2+}. The change in Mg^{2+} ($p<0.05$) and Ca^{2+} ($p<0.05$) levels but not K^+ ($p=0.202$) were more pronounced in diabetic subjects. The change in Mg^{2+} levels in diabetic subjects was associated with QTc prolongation ($p<0.05$).

Conclusions: Significant QTc prolongation occurs at the end of HD in people with and without diabetes, often reaching abnormal levels and appears to be related more to changes in blood electrolytes than glycaemia. The fall in serum Mg^{2+} levels during HD had a larger effect on QTc than K^+ or Ca^{2+} and this appears to have a more pronounced effect in diabetic subjects. The changes in QTc may increase the risk of cardiac dysrhythmia and sudden death in HD patients.

FR-PO636

Markers of Inflammation and Endothelial Dysfunction Are Associated with Cardiovascular Morbidity and Mortality in Type 2 Diabetic Patients with Microalbuminuria Bernt Johan Illum von Scholten,[1] Henrik Reinhard,[1] Tine Hansen,[1] Casper Schalkwijk,[2] Coen Stehouwer,[2] Hans-Henrik Parving,[3] Peter Karl Jacobsen,[3] Peter Rossing.[1] *[1]Steno Diabetes Center, Denmark; [2]Maastricht Univ Medical Center, Netherlands; [3]Rigshospitalet, Denmark.*

Background: Accumulating evidence suggests that inflammation and endothelial dysfunction link type 2 diabetes (T2D) to cardiovascular disease (CVD). We evaluated the predictive value of markers of inflammation and endothelial dysfunction for combined fatal and non-fatal CVD and for all-cause mortality in patients with T2D and microalbuminuria but without known coronary artery disease (CAD).

Methods: Prospective study including 200 patients. All received intensive multifactorial treatment. Markers of inflammation (TNF-α, ICAM-3, hsCRP, SAA, IL-1β, IL-6, IL-8) and endothelial dysfunction (thrombomodulin, VCAM-1, ICAM-1, E-selectin,P-selectin) were measured at baseline. Adjusted models included sex, age, total cholesterol, smoking, HbA1c, creatinine, systolic blood pressure and urinary albumin excretion. Fully adjusted models additionally included NT-proBNP and coronary artery calcium score (CAC).

Results: Participants were 76% men, age (± SD) 59 ± 9 years, HbA1c was 7.9 ± 1.3% and UAER (IQR) was 103 (39–230) mg/d. Occurrence of CVD (n=40) and mortality (n=26) was traced after 6.1 years (median). In adjusted Cox analysis, higher TNF-α predicted the CVD endpoint and mortality (p£0.002). After fully adjustment higher TNF-α remained predictive of both endpoints (p£0.007). Higher thrombomodulin and ICAM-3 were associated with risk of CVD and mortality in adjusted analyses (p£0.05) and predicted mortality after fully adjustment ($p<0.001$). Higher VCAM-1 and ICAM-1 were associated with risk of mortality in adjusted (p£0.002) and fully adjusted models (p£0.005). The composite z-score of all markers of inflammation and of endothelial dysfuntion predicted CVD and mortality (p£0.008).

Conclusions: In patients with T2D and microalbuminuria without known CAD, biomarkers of inflammation and endothelial dysfunction were independently associated with risk of CVD and mortality. Especially TNF-α was a robust predictor, even after adjusting for albuminuria, NTproBNP and CAC.

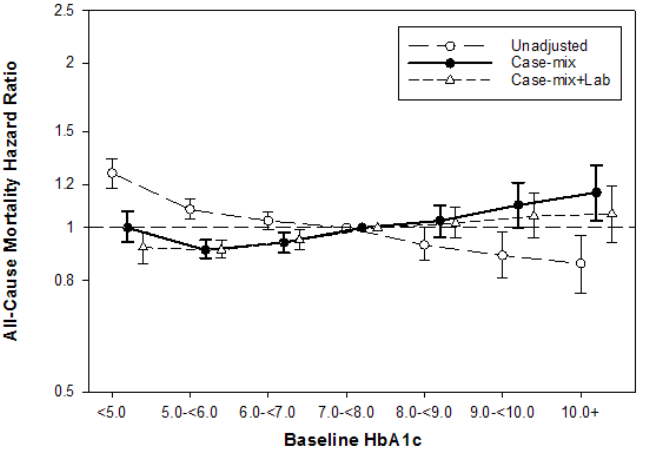
FR-PO637

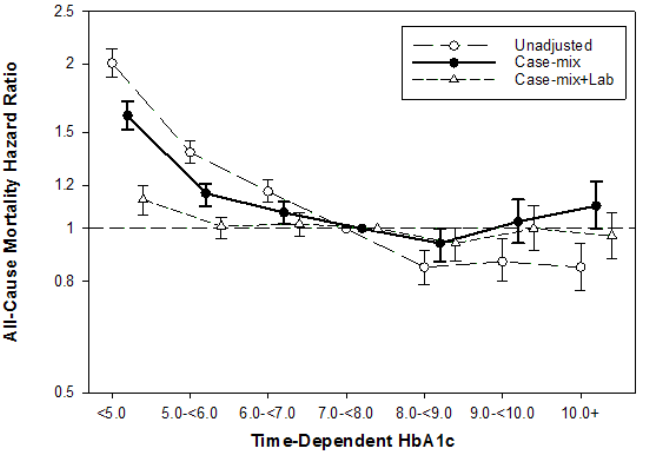
Predictors of Glycemic Status and Associations with Mortality in Incident Diabetic Hemodialysis Patients Connie Rhee,[1] Steven B. Kim,[1] Rajnish Mehrotra,[2] Elani Streja,[1] Danh V. Nguyen,[1] Steven M. Brunelli,[3] Gregory Brent,[4] Csaba P. Kovesdy,[5] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Univ Washington; [3]DaVita Clinical Research; [4]UCLA; [5]UTHSC.*

Background: In the general population, intensive glycemic targets confer higher mortality in diabetics with cardiovascular risk. In diabetic hemodialysis (HD) patients, some but not all studies show that lower glycemic levels defined by HbA1c are associated with higher mortality. We sought to examine predictors of low glycemic status in HD patients, and hypothesized that lower glycemic levels are associated with higher mortality.

Methods: In a 5-year national cohort (1/2007-12/2011) of incident diabetic HD patients with one or more HbA1c measures during the 1st 91-days of dialysis, we examined predictors of low HbA1c (<6%; ref 6-<8%; ≥8% separately examined) using logistic regression. We then examined the association of HbA1c with all-cause mortality. Baseline and time-dependent HbA1c as a proxy of long-term and short-term exposure—mortality associations, respectively, were examined using case-mix+laboratory adjusted Cox models.

Results: Among 63,607 diabetic HD patients, 37% had low HbA1c levels. Female gender and non-Hispanic race/ethnicity; lower BMI and nPCR; and higher serum bicarbonate, creatinine, and albumin were associated with higher risk of low HbA1c. Baseline HbA1c levels <7% were associated with lower mortality. However, time-dependent HbA1c levels <5% were associated with higher mortality.





Conclusions: Baseline HbA1c levels <7% were associated with lower mortality, suggesting that moderately low glycemic status has long-term benefits in diabetic HD patients. Yet time-dependent HbA1c levels <5% were associated with higher mortality, suggesting that very low glycemic status carries short-term risk. Further studies are needed to determine if pharmacotherapies targeting these glycemic ranges reduce mortality in diabetic HD patients.

FR-PO638

Waist-Hip Ratio Is Associated with Renal Hyperfiltration in the Non-Diabetic, Middle-Aged General Population Vidar T. N. Stefansson,[1] Jørgen Schei,[1] Trond G. Jenssen,[1,3] Toralf Melsom,[1,2] Bjorn Odvar Eriksen.[1,2] *[1]Metabolic and Renal Research Group, UiT the Arctic Univ of Norway, Tromsø, Norway; [2]Section of Nephrology, Univ Hospital of North Norway, Tromsø, Norway; [3]Dept of Organ Transplantation, Oslo Univ Hospital, Oslo, Norway.*

Background: Renal hyperfiltration (RHF) is a maladaptive response to increased metabolic stress in the kidneys which may result in chronic kidney disease. Diabetes causes RHF, but whether obesity in non-diabetic persons is a cause of RHF has not been adequately studied in the general population. This study aimed to establish whether RHF assessed by measured glomerular filtration rate (GFR) is associated with obesity independently of metabolic and cardiovascular risk factors.

Methods: We performed a cross-sectional study of a representative sample of 1594 persons recruited from the general population of the municipality of Tromsø, Norway, aged 50-62 without prevalent cardiovascular disease, diabetes or renal disease. GFR was measured by iohexol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR). RHF was defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height.

Results: In multivariable adjusted logistic regression models, the odds ratios (95% confidence intervals) for RHF were 1.56 (1.11-2.18) per 0.10 increase in WHR, 0.82 (0.51-1.32) per 5kg/m2 of BMI and 1.23 (0.92-1.65) per 10 cm of WC. WHR was consistently associated with RHF across different models. Higher BMI and WC were significantly associated with RHF only when an alternative definition of RHF, not adjusted for body weight, was used. Higher BMI, WC and WHR were also independently associated with increasing GFR analyzed as a continuous variable.

Conclusions: Central obesity measured as WHR is associated with RHF and higher GFR independently of age, sex, body weight, metabolic indices (including fasting glucose,

insulin and HbA1C) and cardiovascular risk factors (including ambulatory blood pressure, antihypertensive medication and smoking status). WHR may be a better indicator of the renal effects of obesity than BMI or WC.

FR-PO639

Obesity Associates with High Hemoglobin A1c but Low Alternative Indices in Both Diabetic and Nondiabetic Hemodialysis Patients Mark E. Williams,[1] Neal Mittman,[2] Lin Ma,[3] Julia I. Brennan,[4] Chinu M. Jani,[4] Curtis D. Johnson,[4] Franklin W. Maddux,[3] Eduardo K. Lacson.[3,5] *[1]Joslin Diabetes Center, Boston, MA; [2]Kidney Care of Brooklyn and Queens, Brooklyn, NY; [3]Fresenius Medical Care North America, Waltham, MA; [4]Spectra Laboratories, Rockleigh, NJ; [5]Physician, Lexington, MA.*

Background: The GIDE (Glycemic Indices in Dialysis Evaluation) study is evaluating several glycemic markers in hemodialysis (HD) cohorts with and without diabetes. We have reported that alternative glycemic indices may be elevated out of proportion to hemoglobin A1c (HgbA1c). Because obesity is known to affect markers of glycemia, we examined its association with these indices.

Methods: A combined cohort of 2,394 active HD patients (1,424 with diabetes, 970 without) from 26 U.S. FMCNA facilities had baseline indices [HgbA1c; albumin-adjusted and unadjusted fructosamine (AlbF; F) and glycated albumin (GA) or percent GA] measured Jan-Mar 2013 and monthly until April, 2015. Mean of body mass index (BMI) was determined for the entire cohort. Obesity=BMI³30kg/m². Cox models adjusted by age, sex, race, ethnicity, vintage, HD catheter, baseline comorbidity and laboratory albumin values were to utilized to determine associate between obesity with death outcome.

Results: Average BMI (kg/m², mean±SD) by risk as determined by indices (low=within target range, high=above target range) are shown in (table 1).

Indices	Low Risk	High Risk	p-value
HgbA1c > 7%	28.8 ± 11.4	31.6 ± 8.2	< 0.0001
Percent Glycated Albumin > 15.7%	29.8 ± 12.4	28.9 ± 9.9	< 0.0001
Fructosamine > 285 µmol/L	31.0 ± 14.6	28.7 ± 9.4	< 0.0001
AlbF ≥ 974 µmol/g	29.5 ± 11.8	28.6 ± 7.4	< 0.0001
Glycated Albumin > 300 µmol/L	29.3 ± 11.4	29.2 ± 10.4	0.0008
HgbA1c ≥ 8%	29.1 ± 11.1	31.6 ± 8.7	< 0.0001

The Hazard Ratio (HR) for death was reduced with obesity [HR=0.76, 95%CI (0.62, 0.94), p=0.01].

Conclusions: Obesity is positively correlated with HgbA1c but negatively correlated with other glycemic indices in hemodialysis patients. Further studies are needed to elucidate underlying mechanisms and assess the relationship of these findings to superior survival outcomes in obese HD patients.

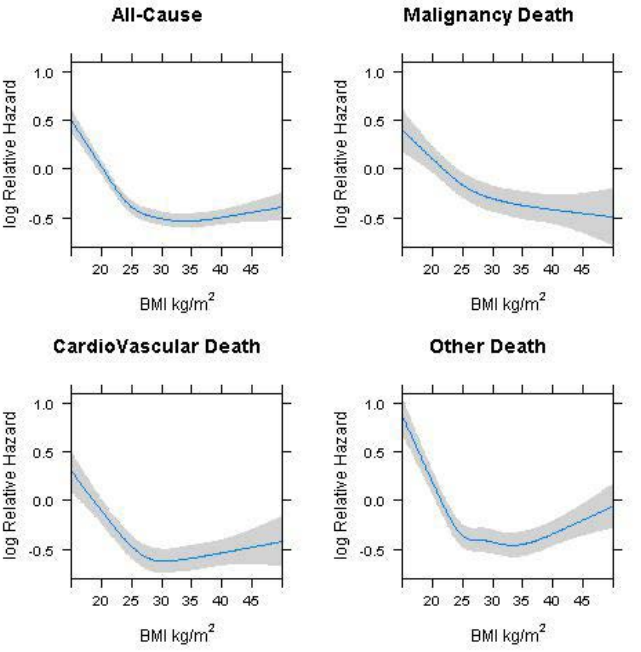
FR-PO640

BMI and Causes of Death in Chronic Kidney Disease Sankar D. Navaneethan,[1] Jesse D. Schold,[2] Susana Arrigain,[2] John P. Kirwan,[3] Joseph V. Nally.[1] *[1]Nephrology, Cleveland Clinic; [2]Quantitative Health Sciences, Cleveland Clinic; [3]Pathobiology, Cleveland Clinic.*

Background: Chronic kidney disease (CKD) is associated with higher risk for cardiovascular related death. In CKD, a higher body mass index (BMI) is associated with a lower risk for death, but cause specific death details are unknown across the BMI range.

Methods: We included 54,506 patients with CKD (two estimated glomerular filtration rate <60 ml/min/1.73 m² 90 days apart; January 2005 – December 2012) from our institutional electronic medical record-based CKD registry. We examined the associations between various causes of death (cardiovascular, malignancy and non-cardiovascular/ non-malignancy related deaths obtained from the State of Ohio mortality files) across the BMI range using the Cox proportional hazards model.

Results: During a median follow-up of 3.7 years (25th percentile-75th percentile: 1.8-5.8), 14,518 patients died. In the multivariable model, an inverted J-shaped association was noted between BMI and overall, cardiovascular, malignancy-related, and non-cardiovascular/ non-malignancy related deaths.



Similar associations were noted for BMI 25-29.9, 30-34.9, and 35-39.9 kg/m² categories. BMI >40 kg/m² was not associated with cardiovascular and non-cardiovascular/ non-malignancy related deaths in CKD. Sensitivity analyses yielded similar results even after including only those with >2 year follow-up, adjusting for proteinuria, and excluding diabetes and hypertension from the models. However, the inverse associations between higher BMI and cardiovascular deaths were not observed among smokers.

Conclusions: In those with CKD, compared to BMI of 18.5-24.9 kg/m², those who are overweight, class 1 and 2 obesity are associated with lower risk for cardiovascular, malignancy-related and non-cardiovascular/non-malignancy related deaths. Future studies are needed to confirm these findings.

Funding: Pharmaceutical Company Support - CCF CKD registry creation was supported by an unrestricted grant from Amgen to the Department of Nephrology and Hypertension at Cleveland Clinic

FR-PO641

Weight Reduction with Low Calorie Diet Reduces Urinary Megalin and Improves Albuminuria in Obese Men Tetsuro Takeda,[1] Akihiko Saito.[2] *[1]Nephrology, Dokkyo Medical Univ Koshigaya Hospital, Koshigaya, Saitama, Japan; [2]Applied Molecular Medicine, Niigata Univ, Niigata, Japan.*

Background: Megalin, an endocytic receptor in proximal tubules, is involved in the mechanisms of albuminuria in diabetic nephropathy. A urinary full-length megalin (C-megalin) assay is linked to the severity of diabetic nephropathy and IgA nephropathy. Also, albuminuria is a frequent sign of obese individuals and could be reduced by losing body weight. We investigated the relationship between level of urinary C-megalin and albuminuria on a weight reduction program in obesity.

Methods: Thirty-three obese male volunteers (age 36.6 ± 6.9 years, BMI >25 kg/m²) were enrolled but 30 subjects completed the 12-week weight reduction program. The program consisted of replacement of evening meal by a low calorie formula food (MICRO-S®) for first 4 weeks and followed by bi-weekly dietary counseling session with nutritionist. Of these, 20 subjects with metabolic syndrome were included (based on the Japanese criteria). Urinary albumin Cre ratio (ACR) and urinary C-megalin were measured at baseline and after the program.

Results: The mean weight loss was 5.2 ± 2.9 kg (5.6% of the original BW). The baseline ACR ranged from 2.8 to 52.9 mg/gCre. After the program, BMI, waist circumference, BP, total cholesterol, and FFA were significantly decreased. HDL-cholesterol and adiponectin were significantly increased. Overall, ACR was not changed (11.9 ± 12.4 → 8.8 ± 5.3 mg/gCre). However, in the cases with ACR >8 mg/gCre at baseline (n=11), ACR was more effectively reduced (22.9 ± 15.1 → 12.7 ± 6.4 mg/gCre) without a change in eGFR. The reduction of ACR was correlated with the reduction of urinary C-megalin. No other parameters like insulin resistance were associated with the reduction of ACR or C-megalin.

Conclusions: Losing BW with a formula food is effective in reducing urinary ACR in obese men. This improvement of ACR is related to the reduction in urinary C-megalin. Since albumin is excreted into urine by its increased glomerular leakage and/or decreased proximal tubular reabsorption via megalin and cubilin, our observations suggest that megalin metabolism in proximal tubules may determine albuminuria in obesity.

FR-PO642

Obesity Management in Patients with Chronic Kidney Disease (CKD): A National Survey Christopher Lawrence,[1] Helen L. MacLaughlin,[2] Ken Farrington,[1] Andrew H. Frankel.[3] *[1]Lister Hospital, United Kingdom; [2]Kings College London, United Kingdom; [3]Imperial College London, United Kingdom.*

Background: Obesity contributes to the development and progression of CKD and may be a barrier to, or increase risks of, transplantation. Evidence for how the renal multi-disciplinary team (MDT) should proceed is limited and sometimes counterintuitive i.e. association of increased weight and better survival on hemodialysis. The study assessed approaches to obese patients with CKD across the UK and describes the availability of, and extent of co-working with, bariatric services.

Methods: An online survey tool was designed and sent by the British Renal Society to UK renal clinical directors and dieticians. The survey focussed on patients with CKD stage ≥ 3, with proteinuria and co-existent Obesity stage II (BMI > 35kg/m^2) as these patients are most likely to progress to ESRD.

Results: 58/71 (82%) of UK units responded with respondents split between dieticians (53%) and nephrologists (47%). Most respondents (78%) thought the prevalence of obesity has increased over the last decade. There was no consensus on the BMI cut off for kidney transplantation: £30, 16%; £35, 71%; ≤40, 12%; none, 2%. The 3 most common actions for initial obesity management were: to provide education/motivation (81%); dietetic referral (60%) and test fasting glucose and lipids (43%). Thereafter only 33% would refer to bariatric services. The main perceived barriers to weight loss were: lack of patient motivation (79%); no funding (60%); lack of services (53%). 54% of renal units co-locate with bariatric services. Only 33% of renal units can refer directly to local/regional bariatric service, the remainder were uncertain of referral pathways (27%) or relied on primary care physicians to refer. Only 5 units (9%) have a joint care pathway for obese patients with CKD undergoing bariatric surgery.

Conclusions: The response to obesity in CKD falls short of National (NICE) guidelines. The increasing prevalence of obesity is a challenge to the renal MDT. Strategies to tackle this include wider recognition of the problem; identifying and sharing best practice and development of a robust evidence base to foster investment in renal dietetic and support services.

FR-PO643

Effects of Renin-Angiotensin Blockade (RASB) on the Components of Early Interstitial Expansion in Patients (pts) with Type 1 Diabetes (T1D) Zarah Khan, Michael Mauer, Maria Luiza A. Caramori. *Medicine and Pediatrics, Univ of Minnesota, Minneapolis, MN.*

Background: Interstitial expansion is important for GFR loss in the later stages of a variety of disease processes, including diabetic nephropathy (DN). The Renin-Angiotensin System Study (RASS; NEJM 2009;361:40) considered whether RASB with enalapril or losartan compared to placebo could slow progression of early DN lesions over 5 years (yrs) in 285 normoalbuminuric (NA), normotensive (NT), normal GFR T1D pts. RASS found no treatment benefit of RASB on DN lesions but observed an unexpected ~50% increase in the light microscopic measures of the fractional volume of renal cortex which is interstitium [Vv(Int/Cortex)]. However, possible effects of RASB on individual Int components, i.e., Int collagen (Col), Int cells (C), peritubular capillaries (PTC) and undefined Int space (S) were not assessed. Here we report these additional studies.

Methods: Baseline and 5-yr renal biopsies from 21 RASS pts (52% males), from a single research center, 7 from each treatment group, with a wide range of change in Vv(Int/Cortex), mean age of 34±10 yrs, and T1D for 11±4 yrs were selected. These pts were matched for age and sex, and selected for electron microscopic (EM) measurements of the fractional volume (Vv) of each of the Int components by masked unbiased random sampling and laborious morphometric point counting methods. Renal volume (RV) was measured by ultrasound and calculated using the kidney's length, width, and anterior-posterior diameter by the formula L×W×AP×0.523.

Results: At baseline, 49% of the Int was made up by Col, 12% by C, 26% by PTC, 7% by S, and 2% by artifact. Overall there was no change in Int composition during RASS. Compared across treatment groups, there were no statistically significant effects of treatment group on the Vv of any of the Int components. RV (171±5 cm^3) remained stable in all groups.

Conclusions: RASS found that NA, NT, normal GFR T1D pts had surprisingly rapid increases in Vv(Int/Cortex) which was uninfluenced by RASB. Here, using EM morphometric analyses, we showed that RASB also did not affect Int composition, since the Vv of each component at 5 yrs was not different from baseline in any of the groups.

FR-PO644

Liraglutide Improves Glycemic and Blood Pressure Control and Preserves Renal Function and Left Ventricular Function in Patients with Type 2 Diabetes Mellitus with Renal Impairment Takeyuki Hiramatsu, Akiko Ozeki, Kazuki Asai, Akinori Hobo, Hideaki Ishikawa, Shinji Furuta. *Nephrology, Konan Kosei Hospital, Konan, Aichi, Japan.*

Background: Diabetes mellitus(DM) is a progressive multifactorial disease associated with cardiovascular complications. To prevent progression of systemic cardiovascular complications in DM patients, glycemic control is important. However using of anti-diabetic agents was restricted in patients with renal impairment. In this study, we examined the efficacy and safety of the glucagon-like peptide analogue, liraglutide to treat type 2 DM patients with renal impairment.

Methods: Twenty type 2 diabetes patients with renal insufficiency (Age; 65.4y, DM duaration;11.9y, eGFR;21.6ml/min/1.73m^2) were enrolled. Anti-diabetic agents were swiched to liraglutide from others. Prior to liraglutide therapy, 9 patients used insulin, 8 used oral antidiabetic agents, and 3 were only diet therapy. During 24 months liraglutide use, we examined the change of blood pressure and renal function. Echocardiography was examined at baseline and 24 months after liraglutide initiation.

Results: Hemoglobin A_1c, and systolic/diastolic blood pressure levels were gradually decreased with liraglutide use. Renal function indicated by eGFR was not changed [table1], and the slope of the reciplocal of serum creatinine was improved after use of liraglutide(p<0.001). Moreover Liraglutide induced ameliorating left ventricular function(LVMI and EF).

	baseline	at 12 months	p value	at 24 months	p value
HbA1c (%)	6.90 ± 0.87	6.15 ± 0.65	0.009	6.04 ± 0.52	0.002
SBP (mmHg)	142.3 ± 12.4	130.9 ± 14.9	0.018	125.1 ± 13.4	0.007
DBP(mmHg)	82.6 ± 9.9	75.3 ± 10.0	0.062	71.4 ± 8.8	0.004
eGFR (ml/min/1.73m^2)	21.6 ± 11.4	24.1 ± 14.6	n.s.	22.4 ± 13.0	n.s.
LVMI (g/m^2)	178.6 ± 59.7	n.d.		143.7± 40.2	0.047
EF (%)	0.60 ± 0.13	n.d.		0.64 ± 0.15	0.395

No adverse events were seen.

Conclusions: These findings suggest that liraglutide therapy for type 2 diabetes patients with renal impairment was safe and effective for decreasing glucose levels and blood pressure. Moreover it preserved renal function and improving left ventricular function.

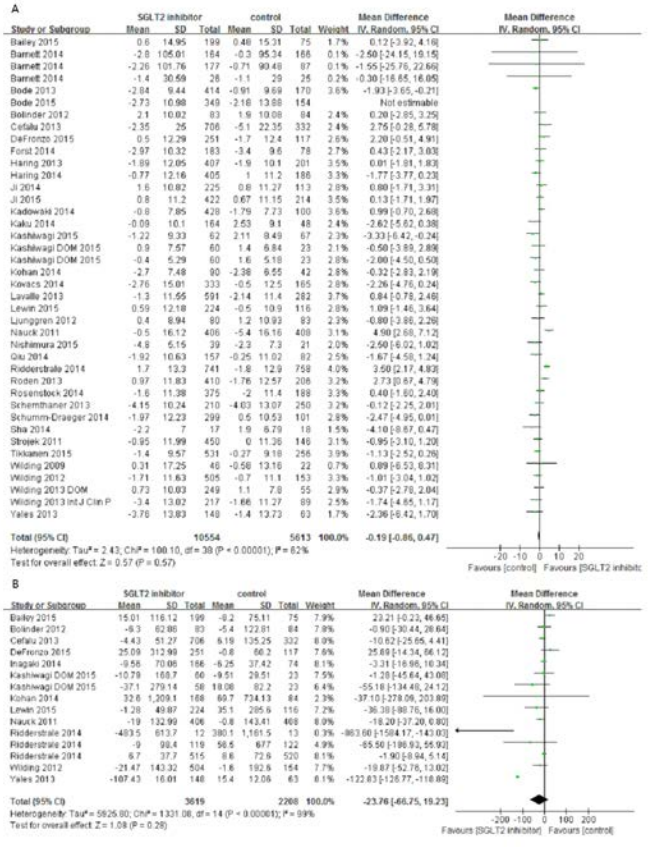
FR-PO645

Do SGLT2 Inhibitors Affect GFR and Albuminuria in Diabetic Patients? A Systematic Review and Meta-Analysis Lubin Xu, Yang Li, Peng Xia, Limeng Chen. *Dept of Nephrology, Peking Union Medical College Hospital.*

Background: SGLT2 inhibitors are a new class of antihyperglycemic drugs that lower blood glucose levels by inhibiting renal reabsorption of glucose. SGLT2 inhibitors can have potential renoprotective capacities through modulation of tubuloglomerular feedback and alleviation of hyperfiltration. However, there are also concerns about deleterious effects on renal function caused by volume depletion.

Methods: We performed this systematic review and meta-analysis to assess the effects of SGLT2 inhibitors on estimated GFR (eGFR) and urinary albumin/creatinine ratio (ACR) in diabetic patients.We conducted a systemic search of Pubmed, Embase, Cochrane Central Register of Controlled Trials and Sinomed through April 2015 to identify published randomized double-blind controlled trials of SGLT2 inhibitors reporting renal outcomes. Two reviewers worked independently to extract data and assess the quanlity of included studies. Random effects model were used in data synthesis.

Results: We retrieved 2279 studies, 53 of which met the predefined criteria. Among included studies, 33 studies examined short-term effect with follow up less than 26 weeks, and 20 studies examined long-term effects with follow-up longer than 48 weeks. 4 studies included subjects with CKD 2-4. SGLT2 inhibitors did not cause statistically significant changes in eGFR (mean change,-0.19 ml/min/1.73m^2, 95% CI, -0.86 to 0.47) or in ACR (mean change, -23.76 mg/g, 95% CI, -66.75 to 19.23).



Subgroup analysis in CKD patients showed a trend of eGFR decrease (mean change: -1.20 ml/min/1.73m^2, 95% CI, -2.65 to 0.26) and trend of ACR reduction (mean change: -59.73 mg/g, 95% CI, -144.49 to 25.04), neither of which were statistically significant.

Conclusions: So far, there is not enough evidence of SGLT2 affecting glomerular filtration rate and albuminuria in diabetic patients.

Meglitinides Increase the Risk of Hypoglycemia in Diabetic Patients with Advanced Chronic Kidney Disease

Pei-chen Wu,[1] Vincent Wu.[2] *[1]Internal Medicine, MacKay Memorial Hospital, Taipei, Taiwan; [2]Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.*

Background: There are few studies on the safety of short-acting meglitinides in diabetic patients with advanced chronic kidney disease (CKD). The aim of this study was to explore the risk of hypoglycemia in patients with severely impaired renal function taking meglitinides in comparison with that on other antidiabetic agents.

Methods: This was a nationwide cohort study using data from the Taiwan National Health Insurance Research Database. We included diabetic patients with advanced CKD who had a serum creatinine level of > 6 mg/dL (equivalent to an estimated glomerular filtration rate of < 15 ml/min/1.73m^2) and a hematocrit level of ≤ 28% and received erythropoiesis-stimulating agent treatment between 2000 and 2010. Fresh users and nonusers of meglitinides were matched using propensity scoring, and the risk of hypoglycemia was analyzed using Cox proportional hazards models with end-stage renal disease and antidiabetic drugs as time-dependent variables.

Results: A total of 2,793 fresh users of meglitinide and 2,793 matched meglitinide nonusers were analyzed. Meglitinide use increased the risk of hypoglycemia (HR, 1.93; 95% CI, 1.56-2.39), and so did sulfonylurea and insulin.

Variable	Hazard Ratio (95% confidence interval)	p-Value
Age (per year)	1.01 (1.01–1.02)	0.001
Male gender	1.20 (1.02–1.41)	0.028
Meglitinide	1.93 (1.56–2.39)	<0.001
Sulfonylurea	1.94 (1.62–2.33)	<0.001
Insulin	2.19 (1.86–2.59)	<0.001
End-stage renal disease	0.53 (0.42–0.65)	<0.001

Conclusions: The use of short-acting meglitinides is also associated with increased risk of hypoglycemia in diabetic patients with advanced CKD.

FR-PO647

Effects of Statins on Diabetic Kidney Disease in Patients with Type 2 Diabetes

Ko Hanai, Tetsuya Babazono, Yasuko Uchigata. *Diabetes Center, Tokyo Women's Medical Univ School of Medicine.*

Background: Renoprotective properties of statins have received much attention; however, a recent large cohort study found no beneficial effect of statins on diabetic kidney disease (DKD). Furthermore, whether there are differences among statins in their effects on the kidneys remains unclear. Here, we compared effects of 4 statins on progression of DKD.

Methods: This was a single-center historical cohort study of Japanese adult ambulatory patients with type 2 diabetes. We studied 412 patients who were newly prescribed one of the following 4 statins: pravastatin, rosuvastatin, atorvastatin and pitavastatin, and who had estimated GFR (eGFR) ³30 mL/min/1.73 m^2. As the control group, 946 patients without prescription history of statins were enrolled. Two outcomes were defined: 1) annual decline in eGFR and 2) progression to a more advanced stage of albuminuria. To adjust for the effects of confounding factors, we used the propensity score (PS) as the covariate. PS was estimated using a multinomial logistic regression model that included 18 clinical parameters. Furthermore, to take into account the varying number and spacing of eGFR measurements, and the variable follow-up period for each individual, we conducted the linear mixed-effects model regression analysis. The intercept and slope were treated as random effects.

Results: During the median follow-up period of 5.3 years (range, 2.0–8.6 years), the adjusted eGFR decline (± standard error) in the control group (1.6 ± 0.1 mL/min/1.73 m^2/year) was significantly slower than that in rosuvastatin (2.4 ± 0.2, p=0.001), atorvastatin (2.6 ± 0.3, p<0.001) and pitavastatin group (2.3 ± 0.3, p=0.036), but not in pravastatin group (1.7 ± 0.2, p=0.780). Next, during the median follow-up period of 4.2 years (range, 0.1–8.5 years), 138 patients showed progression of albuminuria stage. The adjusted hazard ratio (vs. control group) for the albuminuria progression was 0.85 (p=0.690), 0.86 (p=0.679), 1.01 (p=0.980), and 0.69 (p=0.462) in pravastatin, rosuvastatin, atorvastatin and pitavastatin group, respectively.

Conclusions: Statins may have no beneficial effect on the progression of DKD. Instead, some statins are likely to be associated with faster renal function decline.

FR-PO648

Glucose Targets for Preventing Diabetic Kidney Disease and Its Progression: A Meta-Analysis

Marinella Ruospo,[1,2] Valeria M. Saglimbene,[1] Suetonia Palmer,[3,4] Salvatore De Cosmo,[5] Antonio Pacilli,[5] Mariacristina Vecchio,[6] Jonathan C. Craig,[4,7] Giovanni F.M. Strippoli.[1,4,7,8] *[1]Diaverum Medical Scientific Office; [2]Amedeo Avogadro Univ of Eastern Piedmont; [3]Univ of Otago Christchurch; [4]Cochrane Kidney and Transplant; [5]Scientific Inst CSS; [6]Danone Research; [7]Univ of Sydney; [8]Univ of Bari.*

Background: Diabetes is the leading cause of end-stage kidney disease (ESKD). Blood pressure lowering and glucose control are considered central to protection of kidney function in diabetic nephropathy, however the optimal target range for blood glucose for preventing adverse kidney outcomes among adults with diabetes remains unclear. We evaluated the benefits and harms of intensive versus standard glycemic control for preventing the onset and progression of kidney disease.

Methods: Using standard Cochrane methods, we did a systematic review and meta-analysis of randomized controlled trials that evaluated intensive versus standard glycemic control administered to adults and children with type 1 or type 2 diabetes with or at risk of kidney disease. Intensive glycemic control was defined by a treatment targeting an HbA1c below 7% or fasting glucose levels <120 mg/dL. Effect sizes were calculated using a random-effects model. Studies were critically appraised using Cochrane methods.

Results: 10 studies involving 28,885 participants were eligible for inclusion. In studies at low risks of bias, intensive glycemic control had uncertain effects on doubling of serum creatinine (0.71, CI 0.34-1.47) and end-stage kidney disease (1.21, CI 0.12-11.98). Tight glycemic control reduced the onset (0.82, CI 0.71-0.93) and progression (0.56, CI 0.36-0.87) of microalbuminuria. In absolute terms, treating 1000 patients with tight glycemic control for 1 year might prevent 7 experiencing new-onset albuminuria and 22 with worsening albuminuria.

Conclusions: Intensive glycemic control among adults with diabetes had very uncertain effects on developing of ESKD and progression of kidney failure, while providing small clinical benefits on the onset and progression of microalbuminuria.

FR-PO649

Patient Benefits and Cost Savings Predicted for Mineralocorticoid-Receptor Antagonist Treatment of Early and Advanced Diabetic Kidney Disease

Michael Blankenburg,[1] Henri J. Folse,[2] Christina Nowack,[3] Bastian Hass.[1] *[1]Bayer Pharma AG, Berlin, Germany; [2]Evidera, San Francisco, CA; [3]Bayer Pharma AG, Wuppertal, Germany.*

Background: Exploratory studies suggest that mineralocorticoid-receptor antagonists (MRAs) may improve outcomes in patients with diabetic kidney disease (DKD). Finerenone (BAY 94-8862) is a selective, potent and non-steroidal MRA for the treatment of patients with DKD and is currently being studied in two clinical phase III trials, "FIDELIO" and "FIGARO".

Methods: A Markov cohort model was used to emulate disease history, treatment effects, and outcomes for DKD patients with various disease severities (by albuminuria, measured by urinary-albumin-creatinine ratio [UACR], and chronic kidney disease [CKD] stage, measured by estimated glomerular filtration rate [eGFR]). Efficacy of finerenone is accomplished by reducing albuminuria evidenced by phase 2 trial data. The model has US

settings and a 40-year time horizon. Inputs are from NHANES 1999-2008, USRDS 2009, various registries and trials. Sensitivity analyses explored which patient subpopulation would benefit to what extent from finerenone treatment.

Results: The model predicts that finerenone is an effective treatment option for DKD patients, primarily by virtue of reduced risk of end-stage renal disease (ESRD) and renal death (absolute risk reductions [ARR] of up to 9.7% and 9.3%, respectively, for advanced DKD, i.e. macro-albuminuria and CKD3/4) and increased health-related quality of life, and that it would generate cost savings on renal replacement therapy (up to $19,100 for advanced DKD). From a clinical outcomes perspective the optimal time point to begin finerenone treatment appears to be after patients have progressed to either macro-albuminuria or CKD stage 3, as represented by both phase III trial populations. Reduced CV events and CV mortality, however, are greatest (ARR of up to 3.8% and 4.5%, respectively) when finerenone treatment is started in early disease states, as represented by the phase 3 trial population "FIGARO".

Conclusions: Treatment with the MRA finerenone appears to be of significant benefit to patients and the healthcare system, particularly if initiated in advanced stages of DKD.

FR-PO650

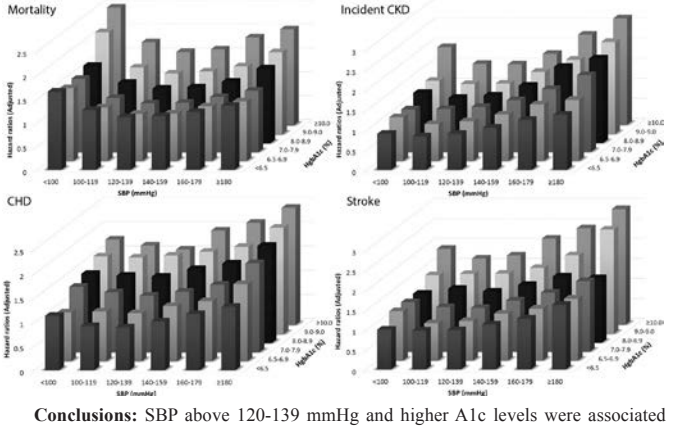
Independent Association of Systolic Blood Pressure and Hemoglobin A1c Levels on Clinical Outcomes in Diabetic Patients with Normal Kidney Function

Aidar Gosmanov,[1] Jun Ling Lu,[1] Miklos Zsolt Molnar,[1] Keiichi Sumida,[1] Praveen Kumar Potukuchi,[1] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]Univ of Tennessee Health Science Center, Memphis, TN; [2]Univ of California, Irvine, CA; [3]VA Medical Center, Memphis, TN.*

Background: Systolic blood pressure (SBP) goal of <140mmHg is recommended for majority of patients with diabetes mellitus (DM). It is however unknown if glycemic control modifies the association of uncontrolled hypertension (HTN) with mortality and morbidity in DM patients.

Methods: We examined 894,661 US veterans with DM and baseline eGFR >60 ml/min/1.73m^2 (mean age 66.6±10.9 years, 97% males, 17% African-Americans). The association of mutually exclusive combined categories of hemoglobin A1c (A1c; <6.5, 6.5-6.9, 7.0-7.9, 8.0-8.9, 9.0-9.9, and ³10%) and SBP (<120, 120-139, 140-159, 160-179, and ³180mmHg) with the risk of all-cause mortality, incident CKD, coronary heart disease (CHD), and stroke was examined in Cox models adjusted for baseline characteristics, statin use, and co-morbidities, using patients with A1c 6.5-6.9% and SBP of 120-139 mmHg as referent.

Results: A total of 221,983 (25%) patients died, and 178,628 (20%), 43,374 (5%) and 36,936 (4%) developed incident CKD, CHD and stroke, respectively, during a median follow up of 7.4 years. SBP displayed a U-shaped association with mortality in each A1c category. Conversely, SBP >120-139 mmHg was associated with a monotonous increase in the risk of CKD, CHD and stroke in all A1c categories. A1c levels were linearly associated with worse outcomes for all end points and in all SBP categories.



Conclusions: SBP above 120-139 mmHg and higher A1c levels were associated with higher mortality and morbidity in diabetic patients, independent of each other. Tight glycemic control may reduce mortality and morbidity across all SBP categories in patients with normal kidney function.

High Acid Diets Increase Urinary Nitrogen Excretion and May Decrease Muscle Mass in Obese Diabetics

Lynda A. Frassetto, Umesh Masharani, Anthony Sebastian. *UCSF, San Francisco, CA.*

Background: We have previously shown that decreasing dietary acid loads with bicarbonate supplements lowers urinary nitrogen (N) excretion in postmenopausal women. Here we examined whether we could lower urinary N excretion in obese diabetics by increasing plant food intake ("Paleo diet") compared with a "usual" acid diet (America Diabetes Association diet).

Methods: 12 obese well controlled type 2 diabetics (7 Paleo, 5 ADA) were enrolled in a 21 day no-weight loss controlled metabolic diet study. Daily protein intake per 2500 kcal averaged 116 g on the Paleo and 127 g on the ADA diets (p=0.7). Fasting arterialized blood and 24-hour urine samples were collected at baseline (pre, days -2 to 0) and the last 3 diet days (on, +19 to 21). Each subject's tests were averaged by period, and the group averages analyzed by one-way ANOVA and between groups by t-test. Urinary N excretion was adjusted per 70 kg. Body composition [total (T), fat free mass (FFM), kg] was measured by bioimpedance (BIS).

Results: mean±SD. ADA or Paleo pre-on; a, p<0.05; Δ Paleo vs Δ ADA: b, p<0.1; c, p<0.05; d, p<0.01.

Index	Test	ADA pre	ADA on	Paleo pre	Paleo on	Δ Paleo vs Δ ADA
BIS	T	108±37	106±36	92±18	90±18	-0.2±1.0
	FFM	74.5±26.7	73.4±26.0[a]	58.2±14.0	57.6±15.7	-0.6±1.4
Urine	Cr N, g/d	0.44±0.13	0.46±0.13	0.46±0.15	0.44±0.11	-0.44±0.83

	Total N, g/d	10.0±3.6	11.7±2.6	11.3±5.9	9.3±4.2	-2.3±1.5[b]
	NAE meq/d	118±47	112±52	92±34	31±24[a]	-55±50[b]

Both groups had equally modest nonsignificant declines in weight.

Conclusions: The higher acid diet had significantly greater loss of fat free mass associated with a greater loss of urinary urea and ammonium. A plant based low acid *weight loss* diet may be better in maintaining lean body mass compared to a usual acid diet.

Clinical Benefit of Pre-Dilution On-Line Hemodiafiltration for Removal of Low-Molecular-Weight Proteins and Fibroblast Growth Factor-23

Kenji Sakurai,[1] Takeshi Saito,[1] Fumi Yamauchi,[1] Hiromi Hosoya,[1] Yoshitaka Kurihara,[1] Daisuke Ishii,[2] Kazunari Yoshida,[3] Kenichi Kokubo,[4] Akihiro C. Yamashita.[5] *[1]Hashimoto Clinic, Kanagawa, Japan; [2]Urology, Kitasato Univ, Kanagawa, Japan; [3]Organ Transplant Medicine, Kitasato Univ, Kanagawa, Japan; [4]Medical Engineering and Technology, Kitasato Univ, Kanagawa, Japan; [5]Chemical Science and Technology, Hosei Univ, Tokyo, Japan.*

Background: Increased concentration of fibroblast growth factor 23 (FGF-23) is reportedly associated with increased risk of cardiovascular complication and mortality in dialysis patients. Therefore, there is a possibility that reduction of FGF-23 levels may improve prognosis of dialysis patients with elevated its levels. We compared the removal performance of low-molecular-weight proteins (LMWP) and FGF-23 between pre-dilution on-line hemodiafiltration (HDF) and hemodialysis (HD) with super high-flux dialyzer.

Methods: The study involved 31 patients (15:HDF, 16:HD, 4 hrs, Qd:600 mL/min). Blood flow rates were 284±20 for HDF, 281±14 mL/min for HD. Replacement fluid volume in HDF was 49.2±9.9 L/session. Removal rates (RR,%) and removal amounts (RA,mg) of urea nitrogen (UN), creatinine, β2-microglobulin (β2-M, MW:11.8kDa), α1-microglobulin (α1-M, 33kDA) and FGF-23 (32kDa) were examined. We followed the changes in FGF-23 levels of patients for 4 month period.

Results: Kt/V, RRs of UN and creatinine were significantly higher in HD than in HDF, whereas RRs and RAs of β2-M, α1-M, and FGF-23 were significantly higher in HDF. RRs of β2-M and α1-M were 80.3±3.7 and 42.0±6.1 for HDF, 73.5±4.1 and 25.0±6.8 for HD, respectively. RR and RA of FGF-23 were 66.9±6.5 for HDF, 51.1±8.3 for HD and 0.11±0.01 for HDF, 0.01±0.01 for HD, respectively.

Conclusions: The results confirmed that HDF was superior to HD in removing LMWP and FGF-23, which are removed mainly by convection. The convection volume can be much easily controlled in HDF than in HD that utilizes internal filtration. The RRs of FGF-23 were 24 points higher than those of α1-MG in both modes despite the small difference in MW, suggesting that distribution volume of FGF-23 was smaller than that of α1-MG. No clear tendency was detected in changes of FGF-23 during 4-month observation period.

FR-PO653

Comparison of Removal Performance of Small- to Large-Molecular-Weight Substances Between Pre-Dilution On-Line Hemodiafiltration and Hemodialysis with Super-High-Flux Dialyzer

Kenji Sakurai,[1] Takeshi Saito,[1] Fumi Yamauchi,[1] Hiromi Hosoya,[1] Yoshitaka Kurihara,[1] Daisuke Ishii.[2] *[1]Hashimoto Clinic, Sagamihara Kanagwa, Japan; [2]Urology, Kitasato Univ, Sagamihara Kanagwa, Japan.*

Background: In pre-dilution on-line hemodiafiltration (HDF), net dialysate flow rate is reduced, because replacement fluid accounts for 30 to 50% of total dialysate flow (Qdtotal). Therefore, removal efficiency of small-molecular-weight substances by diffusion is reduced, whereas that of low-molecular-weight proteins (LMWPs) by convection is

improved. In hemodialysis (HD) using super high flux dialyzer, the increased blood flow rate (Qb) increases amount of internal filtration, thereby improving the removal efficiency of LMWPs. In this study, we compared the removal efficiency of small- to large-molecular-weight substances between HDF and HD to verify the superiority of HDF.

Methods: The study involved 62 patients (31: HD, 31: HDF). Super high flux dialyzers for HD and high-performance hemodiafilters for HDF were used. Qd was 500 for HD and Qdtotal was 600 mL/min for HDF. Replacement fluid volume for HDF was 44.4 ± 10.0 L/session. Qb was 256 ± 23, 257 ± 25 mL/min and Treatment time was 4.1 ± 0.2, 4.0 ± 0.1 hours in HD and HDF, respectively. Removal rates (RR) of b2-microglobulin(b2-M;11.8kDa), prolactin(PRL;23kDa), α1-microglobulin(a1-M;33kDa) and a1-acid glycoprotein(a1-AGP;44.1kDa) were investigated. Kt/V for urea and plasma clearances (CL) of b2-M, PRL and a1-M were measured.

Results: RR (%) of each substance was significantly higher in HDF than in HD ($P < 0.001$): b2-M,79.8 ± 3.2 vs. 70.8 ± 4.7; PRL, 75.3 ± 5.5 vs. 66.2 ± 6.6; a1-M, 40.0 ± 4.1 vs. 31.5 ± 6.4; a1-AGP, 11.9 ± 4.3 vs. 7.4 ± 4.8. Kt/V was 1.56 ± 0.22 (HDF) and 1.51 ± 0.19 (HD). Plasma CLs (mL/min) of b2-M were 95.7 ± 3.6 and 73.6 ± 3.7, those of PRL were 37.3 ± 4.3 and 28.1 ± 5.5 in HDF and HD, respectively.

Conclusions: The performance of HDF in removing LMWPs was superior to that of HD and there was no significant difference in Kt/V in both modes. An increased convection by HDF greatly contributed to improved removal of LMWPs and appropriate control of dialysate flow rate improved the removal efficiency for small molecular substances to the level achieved by HD.

FR-PO654

The Effect of Increasing Kt/V_{urea} in the HEMO Study on Levels of Non-Urea Solutes Timothy W. Meyer,[1] Tammy L. Sirich,[1] Tariq Shafi,[2] Tanushree Banerjee,[3] Neil R. Powe,[3] Thomas H. Hostetter.[4] *[1]Med, Stanford, CA; [2]Med, Johns Hopkins, MD; [3]Med, UCSF, CA; [4]Med, Case Western, OH.*

Background: In the HEMO study, outcomes were no better in patients randomized to "high dose" thrice weekly hemodialysis providing spKt/V_{urea} 1.73 than in those randomized to "standard" hemodialysis providing spKt/V_{urea} 1.32.

Methods: This study assessed whether "high-dose" treatment lowered levels of non-urea solutes. Solutes were measured by LC/MS/MS in plasma samples obtained at least 3 months after randomization in 1281 HEMO subjects.

Results: (mean±sd; CI, confidence interval).

Solute	standard	high-dose	% change (95% CI)	p value
Trimethylamine oxide μM	107±63	97±65	– 9 (–15, –2)	0.007
Phenylacetylglutamine mg/dl	4.6±3.1	4.3±2.6	– 7 (–13, –0)	0.04
Symmetric dimethylarginine μM	4.3±1.4	4.2±1.3	– 4 (–7, –1)	0.018
Asymmetric dimethylarginine μM	0.92±0.24	0.93±0.23	– 1 (–2, 3)	0.74
p-Cresol Sulfate mg/dl	3.3±1.7	3.4±1.7	+ 2 (–4, 8)	0.46

Increasing Kt/V_{urea} caused statistically significant but only modest reductions in the levels of trimethylamine oxide, phenylacetylglutamine, and symmetric dimethylarginine. Mathematical modeling showed that limited reduction in the levels of these solutes was a predictable consequence of the intermittency of treatment. Their reduction ratios with standard treatment are high and the increased intensity of treatment reflected by a 30% increase in Kt/V_{urea} in HEMO's high dose arm could not remove much more solute. Remarkably, increasing Kt/V_{urea} in HEMO caused no reduction in the levels of asymmetric dimethylarginine or p-cresol sulfate, two solutes which have been associated with cardiovascular disease in dialysis patients. Modeling showed that stability of their plasma levels could be accounted for by increased solute production accompanying the increase in Kt/V_{urea} and/or the presence of non-dialytic clearance.

Conclusions: Levels of non-urea solutes may fall only slightly or not at all when Kt/V_{urea} is increased above standard levels for thrice weekly treatment. Treatments that are more effective in reducing solute levels may be required to improve outcomes.

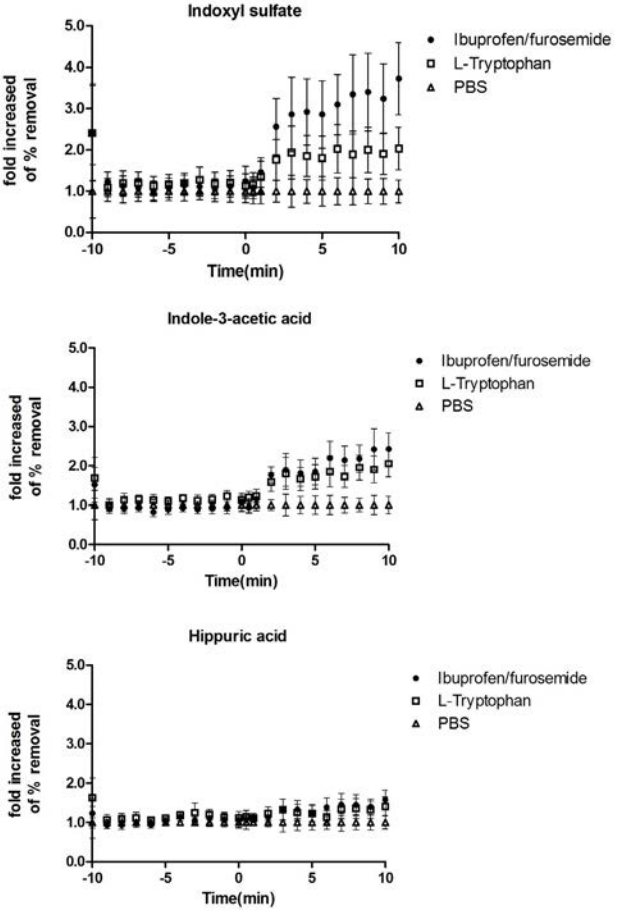
Improved Protein-Bound Uremic Toxins Dialytic Removal with Use of Albumin Binding Competitors: An *In Vitro* Human Whole Blood Study Xia Tao,[1] Stephan Thijssen,[2] Peter Kotanko,[2] Chih-Hu Ho,[3] Michael E. Henrie,[3] Eric W. Stroup,[3] Garry J. Handelman.[1] *[1]Univ of Massachusetts, Lowell, MA; [2]Renal Research Inst, NY, NY; [3]Fresenius Medical Care, Ogden, UT.*

Background: Protein-bound uremic toxins (PBUT) are intensively studied retained solutes that accumulate in chronic kidney disease patients. Efficient removal of PBUTs by hemodialysis (HD) is difficult because of limited free fraction in blood. We propose an innovative method for improving the dialytic removal of PBUTs by increasing their free fractions with use of protein binding competitors.

Methods: The binding properties of indoxyl sulfate (IS), indole-3-acetic acid (IAA) and hippuric acid (HIPA), and their binding competitors, ibuprofen (IBU), furosemide (FUR) and tryptophan (TRP) were studied by rapid equilibrium dialysis (RED) to select suitable model compounds for the HD study. The method was then tested in an *in vitro* HD experimental model with human whole blood spiked with PBUTs. After 10 min baseline test, the binding competitors were introduced upstream of dialyzer blood inlet. The removal of uremic toxins was estimated as the amount leaving dialysate outlet relative to the amount entering blood inlet.

Results: The infusion of IBU and FUR mixture (647μmole/l and 126μmole/l in blood, respectively) in the HD model increased removal of IS from 6.3 ± 0.1 to 15.2 ± 0.3 % (mean ± SEM) (2.4-fold) and IAA removal from 15.9 ± 0.2 to 29.8 ± 0.6% (1.9-fold). TRP (1mmole/l in plasma) infusion increased the removal of IS and IAA to 9.4 ± 0.1% and 26.0 ± 0.3% (1.4- and 1.3-fold, respectively). Only moderate effects were observed in the change of HIPA removal.



Fold change is the ratio of the % removal induced by competitors to PBS.
Infusion of competitors started at 0 min.
Polysulfone dialyzer (surface area 390cm²), Qb=12.5 ml/min, Qd=25 ml/min.

Conclusions: This method increases the removal of PBUTs and has no effect on non-protein-bound solutes. Achieving higher dialytic removal of PBUTs by infusion of binding competitors is feasible and efficient to apply in current HD settings.

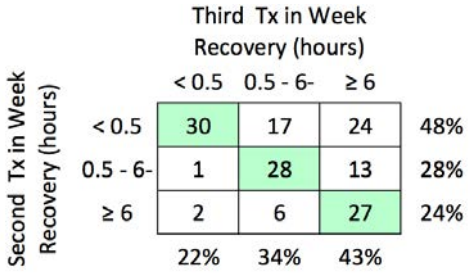
Variable Recovery Time After Hemodialysis Treatment Antonia Harford,[1] Susan Paine,[2] Ronald Schrader,[2] Ambreen Gul,[2] Dana Miskulin,[3] Philip Zager.[1,2] *[1]UNM; [2]DCI; [3]Tufts.*

Background: Prolonged recovery time after hemodialysis (HD) may predict adverse clinical outcomes. In the Frequent Hemodialysis Network a patient's response to the Recovery Question was consistent over time. To determine if this consistency is also present among patients undergoing thrice weekly HD we compared responses to the Recovery Question after each treatment in a given week.

Methods: We asked 256 patients in 3 DCI HD facilities "How long did it take you to recover after your last treatment?" The number of patients who answered the question on the 1st, 2nd, and 3rd treatment was 221, 207, and 200, respectively; 148 patients (57.8%) answered the question on all 3 occasions. Recovery time was categorized as <0.5 hours(h), [3]0.5 h -< 6 h, and ≥ 6 h.

Results: Among the 148 patients who answered the Recovery Question 3 times, recovery times were 6.9, 4.5 and 9.3 hours after the 1st, 2nd, and 3rd HD. There were 46% of patients who had consistent responses on all 3 treatments; 16%, 15% and 15%, had consistently short (<0.5h), moderate (0.5-<6h) and long (≥ 6h) recovery times, respectively. There were 64% who had similar recovery times on the 1st vs.2nd and 1st vs. 3rd HD of the week. Only 57% had consistent recovery times on 2nd and 3rd treatments.



Among the patients with consistent short vs. long recovery, there were no differences in age, race, and vintage. There was a trend for women (59%) to be more likely to have recovery ≥ 6h vs. men (33%) (p=0.09). After the 1st dialysis of the week, recovery was more likely (40%) to be ≥ 6h among patients dialyzed with a dialysate sodium concentration (DNa) <140 mEq/L vs. with a (DNa) ≥ 140 mEq/L (22%). However, similar differences were not observed for the 2nd and 3rd treatments.

Conclusions: There is significant variability among individual patients answers during the week when the recovery question is asked after each treatment.

FR-PO657

Quality Control and Improvement Union of Hemodialysis Centers: A New Management Model Liangying Gan, Mei Wang. *Dept of Nephrology, Peking Univ People's Hospital, Beijing, China.*

Background: With the increasing incidence of end stage renal disease (ESRD) in China, more dialysis facilities are needed. There are huge variations of patient care staffing levels and quality of care. How to maximize the utilization of existing health resources, optimize the management of hemodialysis patients and improve quality control are important issues. The aim of this study was to investigate the feasibility and effects of quality control and improvement union comprised of best hospitals and basic hospitals on patients' medical quality control and improvement.

Methods: The HD union was constructed and specific measures was determined including, 1) Quarterly continuous quality improvement (CQI) meetings, 2) education based on typical cases including extensive discussions, guidelines and latest research results introductions, 3)lectures focusing on key questions, 4) opening green channel and construction of two-way referral system. Paired t-test was used to compare the differences of medical parameters of each hemodialysis center before and two-years after construction of HD union.

Results: The leading center of HD union was the HD center from Peking University People's Hospital. Cooperating centers were other eight centers from class three and class two hospitals. After quarterly CQI meetings, all union members learned how to do medical quality control and improvement, constructed standards and procedures for diagnosis, cure and nursing of their HD center, established the institutions of lab exam and regular round frequency, added necessary examinations and implemented all-around management of HD patients. Green channel for intractable cases transfer were applied successfully. There were statistical improvements of medical quality including dialysis frequency, hemoglobin, calcium, phosphorus, and metabolic acidosis control. Other parameters including Kt/V, iPTH, albumin and Bp improved but without significant difference.

Conclusions: Quality control and improvement union of hemodialysis centers is an effective integrated management model in Beijing China. It can improve medical quality of basic hospitals by balancing the technical advantages of grade A class three hospitals and basic hospitals.

Feasibility of Mindfulness Meditation Training During Dialysis for Patients with Chronic Kidney Disease and Effect on Tolerability of Sessions James C. Wasserman,[1] Daniel Schupack,[2,3] Andrew E. Williams,[4] Paul K. Han,[2,3] George K. Dreher,[3] Mary Bitterauf.[5] *[1]Div of Nephrology, Maine Medical Center, Portland, ME; [2]Center for Outcomes Research and Evaluation, Portland, ME; [3]Maine Medical Center, Portland, ME; [4]Maine Medical Center Research Inst, Portland, ME; [5]MaineHealth, Falmouth, ME.*

Background: Hemodialysis (HD) for CKD entails >/= 12 h of weekly treatment, creating significant distress for patients. Mindfulness-Based Stress Reduction (MBSR) has effectively helped patients with other chronic diseases cope with distressing symptoms and treatments. An abbreviated form of MBSR (Mindfulness Meditation Training, MMT) was incorporated into HD sessions to explore its feasibility, acceptability and potential effectiveness.

Methods: 12 patients were randomly assigned to MMT during HD or usual care. The MMT group underwent weekly 1-h individual sessions during HD for 4 wk. Within-session change in affective response was assessed with the Self-Assessment Manikin, a validated measure of affective valance, arousal and dominance. Anxiety, depression, self-rated health and coping skills were also assessed with validated measures. Patient perceptions were assessed with qualitative interviews at study's end.

Results: In qualitative interviews, patients reported improved tolerability of HD session length, positive intention to continue meditation and no significant issues with MMT sessions or home practice. There were no significant between-group differences in affective response, anxiety, depression, self-reported health or coping skills at baseline or in change over time. Retention rate was 91.7% overall and 83.3% for the MMT group.

Conclusions: MMT appears to be a feasible and acceptable intervention for CKD patients during HD, although effectiveness remains to be demonstrated. Small sample size and low baseline distress levels in the study population likely limited the power to establish effects of MMT. Further research is needed to determine if abbreviated MBSR is sufficient to benefit tolerability of HD in this population. Focus on patients with higher baseline distress levels in future research would increase the likelihood of observing clinical benefit.

FR-PO659

Fluid Management Parameters Are Associated with Dialysis Recovery Time in Conventional Hemodialysis Wael F. Hussein,[1,2] Rohini Arramreddy,[1,2] Marc Reiterman,[2] Sumi J. Sun,[2] Brigitte Schiller.[1,2] *[1]Dept of Medicine, Div of Nephrology, Stanford Univ, Palo Alto, CA; [2]Satellite Healthcare, San Jose, CA.*

Background: Longer dialysis recovery time (DRT) is associated with increased mortality and shorter time to hospitalization. We studied the association of fluid management and hemodynamics with recovery time in conventional hemodialysis (HD) patients.

Methods: Self-reported DRT, obtained by asking "How long does it take you to recover from a dialysis session?", was recorded for 2,689 patients undergoing thrice weekly adequate HD in 46 centers in 3 states. Ordinal logistic regression was used to study the association between patient and dialysis characteristics with DRT. Statistical adjustments were made for patient demographics, comorbidities and body weight.

Results: Forty-three percent of patients were female, 20% were black, median age and vintage were 63 and 3.3 years, median dialysis session length was 203 min (IQR: 180-220). DRT in categories of immediate recovery, >0 to ≤ 2 hours (hrs), > 2 to ≤ 6 hrs, > 6 to ≤ 12 hrs, and > 12 hours, were reported in 27%, 28%, 17%, 9%, and 20% of the patients respectively. In multivariable analysis, longer DRT was associated with female gender, non-black race, lower serum albumin, chronic heart failure, cerebrovascular disease, missed dialysis sessions, higher pre-dialysis systolic blood pressure and larger UF volume. Ultrafiltration rates (UFR) were divided into three categories: <10, 10 to <13, and ³13 ml/kg/hr. Compared to the lowest UFR category, UFR ³13 ml/kg/hr was associated with longer DRT; OR of 1.16 (95% CI 0.99 – 1.36) and 1.28 (95% CI 1.06 – 1.54) in the unadjusted and the adjusted analyses respectively. IDH was associated with longer DRT in the unadjusted (per 10% higher frequency, OR 1.04 [95% CI 0.01 – 1.07]) and adjusted analyses (OR 1.03 [95% CI 1.00 – 1.07]).

Conclusions: Long DRT affects a large proportion of HD patients. Optimizing UFR and controlling IDH are critical measures to improve quality of life for these patients.

FR-PO660

Different Adsorptive Properties of Hemodialysis Membranes May Cause Selective Depletion of Plasma Proteins Jan Mares, Lukas Kielberger. *Nephrology, Charles Univ, Plzen, Czech Republic.*

Background: During hemodialysis (HD) session, plasma proteins are adsorbed to the surface of HD membrane. The resulting biofilm affects both dialyzer permeability and biocompatibility. The aim of this study was to analyze its composition in different HD membranes.

Methods: Twelve long-term HD patients were assigned to 4h HD with three different dialyzers in a cross-over design: ethylene-vinyl-alcohol/EVAL (KF-201-1.8C, Asahi Kasei), polysulfone (F8 HPS, Fresenius), and vitamin E-substituted polysulfone (ViE-18, Asahi Kasei). After HD session, the biofilm was eluted with acetic acid. Obtained proteins (200 μg) were separated by 2-dimensional electrophoresis and fractions showing distinct abundance across groups were identified by tandem mass spectrometry. Blood was sampled along the session to enable subsequent confirmatory studies (ELISA). Data are given as means ± SEM, statistical significance was calculated by ANOVA (general linear model).

Results: The amount of protein eluted from KF dialyzers was higher than from F8 or ViE: 42±9.6, 9±3.3, and 12±6.9 mg, ($p<0.001$), respectively. Totally, 303 protein fractions were detected, 235 common to all eluates. In 48 fractions, spot intensities varied between groups suggesting different adsorption ($p<0.05$). Among them, 11 individual plasma proteins were identified: mannose-binding lectin associated serum protease 1 (MASP1 p=0.012), clusterin (p=0.003), retinol-binding protein 4 (RBP4, p=0.018), α1-microglobulin (AMBP, $p<0.001$), complement factor H (CFH, p=0.004) and its related proteins 1, 2, 5 (FHR, $p<0.001$), fibrinogen β, γ ($p<0.001$), and ficolin-2 (FCN2, $p<0.001$). EVAL membrane bound less FCN2, MASP1, and clusterin but more AMBP, CFH, and FHRs than polysulfone membranes. The most prominent difference was established in FCN2, it was therefore selected for a confirmatory study. It showed a sustained decline of plasma FCN2 levels at all timepoints during HD with F8 but not KF dialyzer to 40±3.6% and 111±5.3% of pre-dialysis levels, respectively ($p<0.001$).

Conclusions: Different HD membranes show variable binding characteristics for particular plasma proteins. It can be responsible for their increased clearance and temporary depletion as demonstrated in case of ficolin-2.

FR-PO661

Mathematical Model of Protein Transport and Plasma Refilling in Hemodialysis Bengt Lindholm,[1] Mauro Pietribiasi,[2] Malgorzata Debowska,[2] Alicja Wojcik-Zaluska,[3] Wojciech T. Zaluska,[4] Jacek Waniewski.[2] *[1]Baxter Novum & Renal Medicine, Karolinska Inst, Stockholm, Sweden; [2]Inst Biocybernetics & Biomedical Engineering, Warsaw, Poland; [3]Rehabilitation and Physiotherapy, Medical Univ Lublin, Lublin, Poland; [4]Nephrology, Medical Univ Lublin, Lublin, Poland.*

Background: Mathematical modeling offers a way to estimate quantities we cannot access directly during hemodialysis (HD). Here we propose a whole-body model of vascular refilling describing water and protein shifts across the capillary membrane during HD. The model was applied to reproduce profiles of plasma volume and serum total protein concentration in patients (pts) undergoing HD.

Methods: The double-pool model (vascular and interstitial space) was based on balance equations of protein mass and water volume in each compartment. The net transport across the capillary wall is the sum of the flow through the membrane's pores and lymphatic flow. The capillary membrane is described according to the three-pore theory. Two transport parameters of the model, the relative number of large pores (αLP) and the total permeability surface area product (LpS) of the capillary membrane, were estimated from volumetric data and blood samples collected in 20 stable, non-diabetic pts during 60 HD sessions.

Results: LpS and αLP were estimated to 10.0 ± 8.4 mL/min/mmHg and 0.062 ± 0.041. The model predicted profiles of plasma volume and serum total protein concentration with an average rootmean-square error < 2%, with larger errors only in pts with very high initial drop in blood volume. When increasing the assumed value of interstitial/serum protein ratio from 0.3 to 0.6, while the total refilling rate remained similar, the value of individual pore flows changed so that filtration through large pores at its peak was 40 % smaller and absorption through small and ultrasmall pores was 80 and 60 % higher, respectively.

Conclusions: The model proposes a mechanistic interpretation of fluid transport processes induced by ultrafiltration during HD. The estimated values of individual flows through each kind of pore and lymphatic absorption represent the relative impact of these not-measurable quantities on total vascular refilling.

FR-PO662

Hemodiafiltration at Increased Plasma Ionic Strength for Improved Protein-Bound Toxin Removal Detlef H. Krieter,[1] Eric Devine,[2] Thomas Koerner,[1] Marieke Rueth,[2] Christoph Wanner,[1] Joachim Jankowski,[3] Horst-Dieter Lemke.[2] *[1]Nephrology, Univ Hospital Würzburg, Würzburg, Germany; [2]eXcorLab GmbH, Obernburg, Germany; [3]Inst of Molecular Cardiovascular Research, Univ Hospital RWTH Aachen, Aachen, Germany.*

Background: Protein-bound uremic toxin (PBT) removal by hemodialysis (HD) is limited resulting in dialysis associated cardiovascular morbidity. Enhancing ionic strength in the dialyzer decreases protein binding and may result in a larger unbound and removable toxin fraction. This was implemented through high sodium concentration ($[Na^+]$) in the substituate of predilution hemodiafiltration (HDF_{mod}).

Methods: *Ex vivo* predilution HDF with blood tested increasing $[Na^+]$ to demonstrate efficacy and hemocompatibility. Hemocompatibility was further assessed in sheep using two different HDF_{mod} setups and $[Na^+]$ between 350 and 600 mmol/L. Safety and efficacy of para-cresyl sulfate (pCS) and indoxyl sulfate (IS) removal was further investigated in a randomized clinical pilot trial comparing HDF_{mod} to HD and standard HDF.

Results: Compared to physiological $[Na^+]$, *ex vivo* HDF_{mod} at $[Na^+]$ of 500 mmol/L demonstrated up to 50 % higher IS removal. Hemolysis in sheep was low even at $[Na^+]$ of 600 mmol/L, not exceeding 0.016 ± 0.001 g/dL of free Hb. In patients, the reduction ratio of free IS was 20 % higher in HDF_{mod} at $[Na^+]$ of 240 mmol/L compared to HD (72.6 ± 6.1 vs. 60.4 ± 16.5 %; P=0.026). Compared to HD and HDF (23.0 ± 14.8 and 25.4 ± 10.5 mL/min, resp.), the dialytic clearance of free IS was 37 and 24 % higher in HDF_{mod} (31.6 ± 12.8 mL/min; P=0.017), but $[Na^+]$ significantly increased over time (arterial plasma at 0 min and 240 min; 132 ± 2 vs. 136 ± 3 mmol/L; P<0.001).

Conclusions: Ionic strength modification with HDF is technically feasible, enhancing PBT removal without adverse effects. More effective HDF_{mod} will require higher temporary $[Na^+]$ in blood, but accumulation of $[Na^+]$ has to be avoided.

FR-PO663

A Filter Placed Along the Path of the Water Treatment System Can Reduce Inflammation in Patients on Chronic Dialysis Elena Mancini,[1] Annunziata Tartaglione,[2] Emanuele Mambelli,[1] Paolo Gaibani,[2] Annalisa Boneschi,[1] Raffaele Longo,[1] Maria paola Landini,[2] Antonio Santoro.[1] *[1]Nephrology Dialysis Hypertension, Policlinico S.Orsola-Malpighi, Bologna, Italy; [2]Inst of Microbiology, Policlinico S.Orsola-Malpighi, Bologna, Italy.*

Background: Contamination of dialysisfluids is one of the most important etiologic factors of chronic inflammation in HD patients, leading to malnutrition/atherosclerosis. Besides intact bacteria and endotoxins, bacterial DNA fragments have to be considered, because, due to their small size, they pass through the most sophisticated water treatment systems.

Methods: We have evaluated the effect on the water quality and patient inflammation of a new ultraphilter placed on the water circuit before the dialysis machine. The filter, with peculiar characteristics (DSU, Nephros Inc, River Edge, NJ), was applied to all the dialysis seats (n=34; 130 patients) in our Centre (Study period, S). At baseline, during S, and the 3 following months without ultrafilter (control period, C), apart from routine controls, every month we performed both conventional microbiological analyses and bacterial DNA fragment research in the dialysate and in the patients.

Results: Conventional microbiological analyses proved negative at every phase of the study, while the search for bacterial DNA was positive in 8/34 samples at baseline (219 genomic copies/reaction). At the end of S, no dialysate sample was still positive (0.029 genomic copies/reaction; p=0.04 sign test). During the following period C, dialysate samples became once again positives. A similar trend was observed in the patient plasma: 113.5 copies/reaction at baseline, 19.9 at the end of S, 84.8 at the end of C (p=0.013). C reactive protein measured in each patient was significantly reduced during S (p=0.04).

Conclusions: In conclusion, the traditional treatment did not prevent the appearance of bacterial DNA fragments in dialysis fluids. This can foster the onset of inflammation. The ultraphilter tested actually improved the purity of the water and its regular use seems to reduce microinflammation. This could, in turn, have repercussions on different aspects such as resistance to erythropoietin as well as the processes of precocious atherosclerosis.

Effect of Computationally-Optimized Vibration on Clearance of Solutes During In Vitro Hemodialysis Katherine N. Gharibian,[1] Susan J. Lewis,[1] Joseph L. Bull,[2] John J. Pitre,[2] Bridget A. Scoville,[3] Thomas Velenosi,[4] Brad Urquhart,[4] Noel Perkins,[5] Bruce A. Mueller.[1] *[1]College of Pharmacy, Univ of Michigan, Ann Arbor, MI; [2]Dept of Biomedical Engineering, Univ of Michigan, Ann Arbor, MI; [3]Saint Alexius Medical Center, Hoffman Estates, IL; [4]Dept of Physiology and Pharmacology, Western Univ, London, ON; [5]Dept of Mechanical Engineering, Univ of Michigan, Ann Arbor, MI.*

Background: Our previous *in vitro* studies demonstrated that the addition of vibration enhances dialytic clearance of solutes by a median of 18% during CVVHD. In this study, we applied computational fluid dynamics to determine vibration's effects during hemodialysis and validated them using an *in vitro* hemodialysis model.

Methods: Based on predictions of a computational fluid dynamics model, two vibration settings (120 Hz/0.176 mm & 360 Hz/0.0765 mm) were selected and applied to a F8 dialyzer (1.8 m^2; Fresenius) during *in vitro* hemodialysis using blood/dialysate flow rates of 300/600 mL/min, respectively. Mean transmembrane clearances were analyzed for six solutes: urea, creatinine, gentamicin, vancomycin, indoxyl sulfate, and hippuric acid. Albumin, free hemoglobin, and LDH concentrations were measured after 4 hours of dialysis with applied vibration to assess blood and dialyzer integrity.

Results: A one-way ANOVA yielded no significant difference between the control group and non-control vibration groups in solute clearance: urea, $F(2,27)=1.801$, $p=0.184$; creatinine, $F(2,27)=2.525$, $p=0.099$; gentamicin, $F(2,33)=0.273$, $p=0.763$; vancomycin, $F(2,33)=0.003$, $p=0.997$; indoxyl sulfate, $F(2,33)=0.390$, $p=0.680$; hippuric acid, $F(2,33)=0.398$, $p=0.675$. Four hours of vibration had no significant effect on blood and dialyzer integrity as measured by concentrations of albumin ($F(1,22)=0.185$, $p=0.735$), hemoglobin ($F(1,22)=1.038$, $p=0.319$), and LDH ($F(1,22)=0.185$, $p=0.672$).

Conclusions: Although vibration has been shown to enhance solute clearance in CRRT and PIRRT, in this study, computationally-optimized vibration failed to significantly enhance solute clearance in an *in vitro* hemodialysis model using flow rates typically seen with intermittent hemodialysis.

Sevelamer Hydochloride Improves Oxidative Stress in Maintenance Hemodialysis Patients Siren Sezer, Bahar Gurlekdemirci, Cihat Burak Sayin, Emre Tutal, Zeynep Bal, Fatma Nurhan ozdemir Acar. *Dept of Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey.*

Background: Oxidative stress plays a key role in the pathogenesis of cardiovascular diseases . Superoxide dismutase (SOD) and malondialdehyde (MDA)are well-known antioxidant enzymes that detoxifies advanced glycation end products (AGEs). We thought that avoiding calcium intake and through pleiotropic effects, sevelamer hydrochloride might be a differential influence in terms of oxidative stress. The aim of this study is to evaluate the effects of phosphate binders (PBs) on the components of the oxidative stress and clinical and biochemical parameters including pulse wave velocity in our maintenance hemodialysis (MHD) patients.

Methods: A total of 111 patients (mean age: 52.2 ± 14.3 years; mean duration of dialysis: 9.7 ± 4.6 years) undergoing maintenance hemodialysis and using the same PBs at least one year were enrolled into the study. Patients were divided into two groups according to usage of PBs as sevelamer based PB (group 1; n: 84 and calcium based PB (group 2; n.27). Biochemical parameters were assessed from monthly clinical visits. Serum AGE, MDA and SOD levels were determined by ELISA method. Pulse wave velocity (PWv) was determined by using the SphygmoCor system.

Results: Groups were similar in means of demographic characteristics and URR levels. Patients in group 1 had significantly lower AGE (p: 0.018), higher MDA (p: 0.027) and SOD (p: 0.012) levels. Although both baseline and first year PWv values were similar in two groups, PWv values significantly decreased in group 1 (p: 0.001) where increased in group 2 (p: 0.021) in the second year analysis. In linear regression analysis, serum AGE levels were detected as the unique predictor of DPWV (p: 0.005). For each 1 u/mL of increased level of AGE resulted in 0.53 cm/sec of increased level of PWv (p: 0.005, CI: 0.016-0.089).

Conclusions: Despite similar phosphorus levels and dialysis adequency, sevelamer decreases serum AGE and increases serum MDA and SOD levels as well as improves PWv. Thus, sevelamer improves the oxidative stress and cardiovascular risk by pleiotropic effects when compared to calcium based phosphate binders.

FR-PO666

Preliminary Study About Optimal Dosage of Heparin Locking Solution to Maintain the Patency of Hemodialysis Catheter Jung-woo Noh, Eunjung Kim, Ja-Ryong Koo. *Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym Kidney Research Inst, Seoul, Korea.*

Background: Hemodialysis catheters(HC) are routinely heparin locked to maintain patency. This practice may cause bleeding episodes. The amount of heparin for heparin locking solution at many dialysis centers has been decreased recently to reduce the risk of bleeding. However, the effect of this change on patency of HC is unknown. We compared the patency of HC between four types of heparin amount of 4000, 5000, 7500, and 15000 units(U).

Methods: This observational study included 126 chronic hemodialysis patients using HC in Hallym University Medical Center from March 2011 to July 2014. 29 patients received a 4000 U, 41 patients received a 5000 U, 44 patients received a 7500 U and 41 patients received a 15000 U of heparin. The primary outcome was composite outcome: frequency of thrombolytic instillation, change of hemodialysis line due to dysfunction of HC and HC obstruction due to thrombosis. We also compared activated partial thromboplastin time (aPTT) levels between groups just before and 10 minutes after the end of each hemodialysis.

Results: The composite outcome were 2.44±5.42, 1.06±3.46, 0.40±1.18 and 0.52±1.16 episodes/100 catheter-days, respectively(p=0.03). 4000U group showed especially high rate of events compared to other groups receiving more than 5000 U of heparin. However, event rate of HC obstruction due to thrombosis was not significantly different: zero episodes/100 catheter-days for 4000IU and 15000IU groups, 0.01±0.05 episodes/100 catheter-days for 5000IU group and 0.14±0.61 episodes/100 catheter-days for 7500 IU group. At 10 minutes after heparin lock, prolonged aPTT was observed in all groups. When 10 minutes aPTT levels between 4000 U group and other groups are compared, those of 7500 U(p=0.007) and 15000 U(p=0.004) groups were significantly prolonged. But there were no bleeding complications in those groups.

Conclusions: Low concentration heparin lock solution with total amount of 4000 U do not increase HC obstruction due to thrombosis, but increase in thrombolytic instillation and set change. Higher concentration heparin lock solution with total amount over 7500 U prolonged the aPTT without bleeding complication.

FR-PO667

Association Between Depressive Symptoms and Dependency with Mortality in Hemodialysis Patients After 5 Years of Follow-Up Joaquin Manrique,[1] Maria del cielo Mena,[2] Eva Cerdán,[2] Laura Catalan.[2] *[1]Servicio de Nefrologia, Complejo Hospital de Navarra, Pamplona, Spain; [2]Nursing Staff. Servicio de Nefrologia, Complejo Hospital de Navarra, Pamplona, Spain.*

Background: The prevalence of depression and its role in mediating survival of patients with end-stage renal disease (ESRD) has been highly controversial. Moreover, according to the population ages, their limitations in performing daily activities affect their well-being as well as increase the burden on caregivers and the use of health services.

Methods: We determine whether depressive symptoms and dependency are associated with mortality in a longitudinal study of 148 hemodialysis (HD) outpatients followed for 5 years. Depressive symptoms were assessed using the Beck Depression score (BDs), and dependence by Barthel scale (BS) performed by nursing HD staff.

Results: 26.8% of patients had depressive symptoms (BD>10) and the mean baseline BDs was 11.4+/-8.1). 23% patients were moderate or severely dependent (BS<90). 40.5% died during the study follow-up period (a rate similar to that found in this population). We observed a significant association between BS and BDs (r^2=-0.5; p<0.001). Patients with greater disability (BS<90) had worse depressive score (p<0.001). After 60 months of follow-up, survival rates were 80.5% for BDs≥8 and 94.3% for BDs < 8 (p=0.05), and 71.4% for dependent and 95.5% for no dependent patients (p<0.001). Other variables, including age, gender, and dialysis period, were not significantly associated with mortality. Cox proportional hazards regression was performed to predict the mortality hazard associated with baseline level of depressive affect and dependence, controlling for the effects of variation in patient age and dialysis duration.

Conclusions: Our study shows that the disability in self-care and the presence of depressive symptoms are common among patients on haemodialysis. Both of them may act as independent risks factors for mortality. Strategies could be helpful to routinely identify those dialysis patients at risk of functional impairment and depression to limit their disabilities. Self-report scales and those performed by nursing staff could improve the integral treatment of those patients.

FR-PO668

Limitations of Access Recirculation due to a Low Access Flow Rate on Middle Molecule Clearance During Post-Dilution Hemodiafiltration J. Ken Leypoldt,[1] Markus Storr.[2] *[1]Renal Therapeutic Area, Baxter Healthcare Corporation, Deerfield, IL; [2]Research & Development, Gambro Dialysatoren GmbH, Hechnigen, Germany.*

Background: Post-dilution hemodiafiltration (HDF) with a high convective volume (CV) is associated with lower overall patient mortality, potentially due to high middle molecule (MM) clearance from the patient (Kp). A higher CV can most readily be achieved by extending the treatment time or increasing the blood flow rate (BFR); however, the effect of access recirculation due to a low access flow rate (AFR) when increasing the BFR on MM Kp during HDF has not been previously quantified.

Methods: A theoretical mass balance model for assessing the effect of a low AFR on MM Kp was formulated. Access recirculation was assumed to occur when the BFR exceeded the AFR. The model demonstrated that MM Kp was dependent on HDF membrane properties, AFR, BFR, CV and the fluid removal rate from the patient (FRR).

Results: Example results are tabulated for a patient with a hematocrit of 33% at different AFRs and BFRs maintaining a fixed filtration fraction of 25% during a 4-hour HDF treatment with a FRR of 0.5 L/hour. MM filter clearance was assumed to depend on CV with a diffusive clearance of 75 mL/min and a sieving coefficient of 0.7:

	MM Kp (mL/min) at BFR (mL/min)/CV (L)					
AFR (mL/min)	at 300/18.0	at 320/19.2	at 340/20.4	at 360/21.6	at 380/22.8	at 400/24.0
≥400	127.5	131.0	134.5	138.0	141.5	145.0
320	127.5	131.0	129.8	129.0	128.5	128.1

When the AFR is higher than the BFR, MM Kp increases with increasing CV. At low AFR, increasing the BFR above the AFR resulted in a lower MM Kp than expected. Indeed, increasing the BFR above the AFR can even lead to a reduction in MM Kp.

Conclusions: High convective volumes during post-dilution HDF achieved by using high blood flow rates may not result in higher middle molecule clearance if the access flow rate is low. Routine assessment of access recirculation or access flow rate may be necessary during post-dilution HDF with high blood flow rates to improve patient outcomes.

Protein Biofilm and Its Relation to Dialyzer Permeability for Middle Molecular Weight Markers in Three Polysulfon Membranes Lukas Kielberger, Jan Mares. *1st Dept of Internal Medicine, Charles Univ Teaching Hospital, Plzen, Czech Republic.*

Background: Membrane permeability, particularly in terms of middle molecular clearances, is largely dependent in vivo on the formation of a protein biofilm. Our aim was to assess its dynamics during HD session together with molecular composition of the biofilm.

Methods: 12 HD patients were assigned in a cross-sectional design to Xevonta® Hi23 (B-Braun, 2.3 m^2), CorDiax FX100® (Fresenius, 2.2 m^2) and Polyflux® 210H (Gambro, 2.1 m^2) dialyzers. Blood pre- and post- dialyzer was sampled at 0, 15, 60, and 240 min; spent dialysate was collected over the first 15 min and then until the end of the session. b2 microglobulin (b2M), myoglobin (MB), retinol-binding protein (RBP), and α1-microglobulin (α1m) levels were determined as permeability markers covering an interval of molecular weight (MW) 11-26 kDa. After HD, protein biofilm was eluted from dialyzer and subjected to proteomic analysis.

Results: At the beginning, Xevonta and FX dialyzers showed significantly higher in vivo sieving coefficients for all MWs up to 26 kDa (α1m) than Polyflux dialyzer (p<0.01). After 15 min, Xevonta and FX permeability decreased significantly (p<0.01) in all MW classes while in Polyflux, only $MW^3$21 kDa (RBP4) were affected (p<0.01). The total protein content of membrane biofilm was similar in all three dialyzers: 118±85, 41±10, and 40±17 mg protein per dialyzer for Xevonta, FX, and Polyflux, resp. Significant differences in protein composition were captured in 48 out of 231 protein fractions. Among them, complement factor H-related protein 3 (FHR3), insulin-like growth factor binding protein 4 (IBP4), or multiple fibrin fragments (FDP) were identified. While FDP and IBP4 were prevalent in eluates from FX and Xevonta dialyzers (p=0.005 and 0.001, resp.), FHR3 was abundant in Xevonta only (p=0.01).

Conclusions: Even with modern biocompatible dialyzers, in vivo permeability decreases along HD session, probably due to biofilm formation. The decrease occurred irrespective of total protein adsorbed, compromising rather membranes primarily more permeable and higher MWs. Differences in biofilm composition are complex and may impact both dialyzer permeability and biocompatibility.

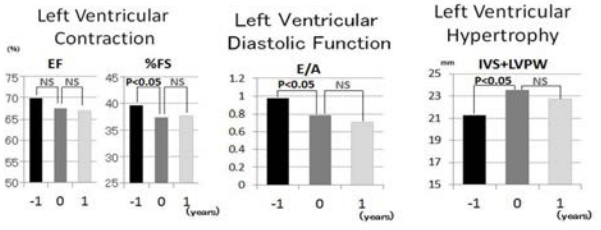
Protective Effects of Intravenous L-Carnitine (LC) Administration on Development of Cardiomyopathy in Hemodialysis (HD) Patients

Takuhisa Uchino,[1] Jyunichiro Hashiguchi,[1] Satoshi Funakoshi,[1] Hiroshi Ichinose,[1] Osamu Sasaki,[1] Kenji Sawase,[1] Miki Yano,[1] Yutaka Mori,[3] Kazunori Utsunomiya,[3] Yoko Obata,[2] Tomoya Nishino,[2] Miwa Shirahama,[1] Takashi Harada.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Univ Graduate School of Medicine, Nagasaki, Japan.*

Background: Due to loss via dialyzer patients on maintenance HD often suffer from dialysis-related carnitine deficiency, causing various clinical symptoms. Carnitine Consensus Conference in 2003 convened by The National Kidney Foundation had reported that the level of evidence was "moderate" for cardiomyopathy.Recent studies have shown that L-carnitine can improve left ventricular (LV) function in HD patients. In this study we aimed to investigate whether intravenous administration of LC can prevent the development of cardiomyopathy in HD patients as assessed by M-mode ultrasound cardiography (UCG).

Methods: Thirty-eight HD patients without reduced left ventricular function were treated with intravenous administration of 1000mg / body of LC at the end of every HD session for 12 months. M-mode UCG assessments were undergone in all subjects at the tree points; 1 year prior to the treatment, the start of LC administration and1 year after the treatment.

Results: As shown in Figure 1, average %FS (fractional shortening) significantly declined during 1 year before the start of LC, then stabilized after the treatment, suggesting LC administration might protect the progression of LV contraction impairment. Average early diastolic filling velocity (E) / atrial filling velocity (A) ratio showed similar pattern, suggesting LC treatment could be protective in LV diastolic disorder. LC treatment also might delay LV hypertrophy progression.



Conclusions: Intravenous LC administration can be a candidate therapy for protection of the development of cardiomyopathy in HD patients.

Symptoms and Quality of Life Among Patients Receiving HD

Mark L. Unruh,[1] Kim J. Cox,[2] Stephen H. A. Hernandez,[2] Sanah Parvez,[1] Mark Parshall.[2] *[1]Div of Nephrology, Univ of New Mexico; [2]College of Nursing, Univ of New Mexico.*

Background: Health-related quality of life (HRQOL) assessment is a required condition of coverage for HD providers, but standard measures may not adequately reflect the impact of symptoms and treatment on QOL for patients receiving HD or the concerns that matter most to them. The purpose of this qualitative study is to more fully characterize patients' perspectives on the symptoms and treatment experiences affecting their QOL.

Methods: We conducted semi-structured interviews with a diverse sample of 50 HD patients (48% Female; 42% Hispanic; 30% American Indian; 14% Black; 12% Non-Hispanic White) to elicit their experiences with diagnosis and treatment of ESRD and the symptoms and aspects of treatment that have the greatest impact on their QOL. Interviews were audio-recorded, transcribed, and analyzed for themes using an interpretive-approach.

Results: Participants recalled that the initial diagnosis of ERSD was received with shock and denial. Over time, patients reported that QOL was associated with "taking control" of some features of their treatment. Common symptoms associated with HD, such as cramping and fatigue, were described as potentially manageable when patients were able to participate in decisions about fluid removal and scheduling of HD treatments. Patients who formed a partnership with their providers to negotiate fluid removal reported fewer episodes of severe cramping and improved QOL. Similarly, being able to choose among a variety of days and shifts for HD treatment enabled patients to manage fatigue, work hours, travel, and attendance at social events. These factors were critically important to the QOL in our relatively young sample (median age = 53; median duration of HD treatment = 4 years).

Conclusions: This is one of the largest and most diverse qualitative studies of symptoms among patients undergoing HD. There were few differences in symptoms or the impact of treatment on QOL among racial and ethnic groups. Findings highlighted the importance of fluid management and fatigue to patient experience.

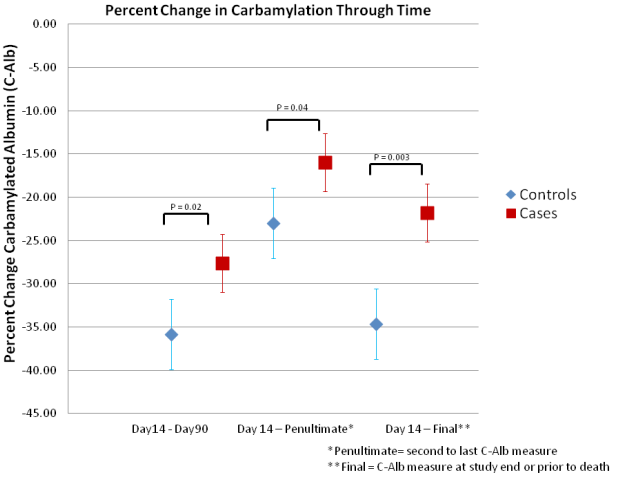
Longitudinal Measures of Protein Carbamylation and Mortality on Dialysis

Sahir Kalim,[1] Anders H. Berg,[2] Rayhnuma Ahmed,[1] Joshua Wibecan,[1] Caitlin A. Trottier,[1] S. Ananth Karumanchi,[2] Ravi I. Thadhani.[1] *[1]MGH; [2]BID.*

Background: Single time-point measures of carbamylation have recently been associated with mortality in dialysis patients. This study investigated whether repeated measurements of carbamylation over time, allowing calculation of the rate of change, improved on mortality prediction.

Methods: In a nested case-control study, we measured % carbamylated albumin (C-Alb, a measure of carbamylation load) in a cohort of incident hemodialysis patients. 122 subjects who died within 1 year of initiating dialysis (cases) were randomly selected and matched for demographics to 244 individuals who survived at least 1 year on dialysis (controls). C-Alb was assayed within 14 days of dialysis initiation and every 90 days for 1 year or until death. Logistic regression quantified case-control differences.

Results: In adjusted models, there was no case-control difference in day14 C-Alb (P=0.83) and, as expected, carbamylation decreased in both groups with dialysis initiation. By day 90, unit increase in C-Alb was predictive of 1-year mortality (OR 1.7, 95%CI 1.1-2.8; P=0.02) despite no differences in Kt/V. Final C-Alb (last measure taken at study completion or preceding death) was a stronger mortality predictor than C-Alb from any other time point (OR 2.4, 95%CI 1.4-4.0; P=0.003). A smaller % decrease in C-Alb between any 2 time points carried an increased mortality risk (e.g. C-Alb from day 14 to final = -21% in cases vs. -35% in controls; OR 1.6, 95%CI 1.2-2.0; P =0.002). Sensitivity analysis showed follow up time did not bias the results.



Conclusions: C-Alb decreases with dialysis initiation. Smaller decreases in C-Alb over time, resulting in persistently high carbamylation, may herald increased mortality risk during year 1 of dialysis. Because dialysis intensity and amino acid therapy reduce carbamylation, the utility of C-Alb as a therapeutic guide should be investigated.

Recruitment Challenges in the Blood Pressure in Hemodialysis Pilot Study

Jennifer J. Gassman,[1] Dana Miskulin,[2] Philip Zager,[3,4] David W. Ploth,[5] Manisha Jhamb,[6] Lavinia A. Negrea,[7] Mahboob Rahman.[7] *[1]Cleveland Clinic; [2]Tufts; [3]UNM; [4]DCI; [5]MUSC; [6]Univ of Pittsburgh; [7]Case Western.*

Background: The optimal BP target in hemodialysis (HD) patients is unknown. The Blood Pressure in Dialysis (BID) Pilot Study is an ongoing NIDDK/Dialysis Clinic Inc. funded multi-center randomized trial treating hypertensive HD patients to a standardized predialysis systolic BP (SDUSBP) of 110-140 vs.155-165 mm Hg, to assess feasibility and safety and inform the design of a full-scale trial.

Methods: We consented 281 participants who entered baseline from 12/2011 to 1/2015. We randomized 126 participants. Achievement of the SDUSBP goal was assessed by determining 2-week running mean SDUSBP in each patient. Participants are followed for 12 months. BP was measured at each dialysis session, home, and ABPM. BP and medications were backtitrated until predialysis SDUSBP was greater than 155 mm Hg. Outcomes include protocol adherence, SDUSBP adherence and left ventricular mass by MRI. To recruit, we identified hypertensive patients, 125 approached for consent refused. Reasons for refusal included perception of study being burdensome 34 (27%) and reluctance to change medications/goals 10(8%).

Results: Of the 281 participants who entered the baseline period 155 (55%) were not randomized, 38(25%) changed their minds, 9(6%) unlikely to adhere, 6(4%) had contraindications to MRI, 6(4%) could not perform required procedures, and 65(42%) were

unable to achieve the lower limit goal of a SDUSBP >155 mm Hg despite backtitration. Retention has been excellent. Patient characteristics are balanced between treatment arms. There is good separation between arms.

Conclusions: We anticipate that a Phase III BID clinical trial will require >1200 participants. MRI will be eliminated and the protocol will be simplified. Routine BPs run higher than SDUSBP and too low a BP was the primary reason for failure to randomize. The anticipated revised protocol will facilitate recruitment and randomization. Clinical sites should plan to enroll twice the number that need to be randomized to achieve the randomization target in the full-scale study.

FR-PO674

Association of Time-Averaged Concentration of Hemoglobin with Mortality: Results from a Large U.S. Hemodialysis Cohort Hanjie Zhang,[1] Stephan Thijssen,[1] Peter Kotanko.[1,2] *[1]Renal Research Inst, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

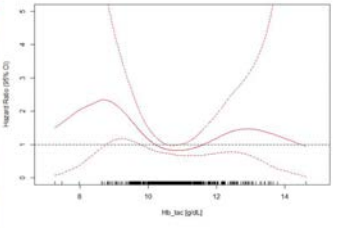
Background: In hemodialysis (HD) patients the time averaged concentration of hemoglobin (Hb_tac) can be estimated from pre- and post-HD hemoglobin (Hb) levels. It has been suggest that Hb_tac may be an appropriate indicator for anemia management (Siga, Int Urol Nephrol 2014). However, the association between Hb_tac and mortality has not yet been evaluated.

Methods: We analyzed Hb data obtained by Crit-Line™ monitor (CLM) in chronic HD patients. A 6-month baseline period with at least 10 CLM measurements preceded a 12-month follow-up during which outcomes were noted. We used Hb values from HD sessions following a short interdialytic interval. Hb_tac was computed as follows (Krisper, NDT 2003): Hb_tac = Hb_pre * 0.5 + Hb_post * 0.38 + 1.28. We defined Hb_pre as the average Hb between minutes 5 to 20 from the start of the CLM recording, and Hb_post as the average of Hb between minutes 5 to 20 from the end of the CLM recording. The relation between Hb_tac during baseline and mortality was explored by spline analysis of hazard ratio (HR).

Results: We studied 982 patients (figure 1A) with a total of 19,142 CLM measurements. Average Hb_tac was 10.72 g/dL (SD 0.81, range 7.27 – 14.62 g/dL). The mortality rate during follow-up was 11.6 per 100 patient-years. The minimal HR (figure 1B) was 0.82 at Hb_tac of 10.87 g/dL. The solid line represents mean HR, the dotted lines 95% confidence intervals.

Figure 1 A: Descriptive statistics (EPO, erythropoietin) B: Spline analysis of hazard ratio for mortality as a function of Hb_tac.

Characteristics	Mean (SD)
Demographics	
Gender [% male]	59
Age [years]	62.1 (15.2)
Dialysis vintage [years]	3.9 (4.1)
Laboratory parameters	
Serum albumin (g/dL)	4.0 (0.3)
Hgb (g/dL)	10.9 (0.9)
Medication	
EPO dose (Units per treatment)	2589 (3386)



Conclusions: Hb_tac is associated with mortality, levels around 10.9 g/dL are associated with the lowest mortality risk. Studies are required to further explore methods to estimate Hb_tac based on Hb measurements by the CLM and the usefulness of Hb_tac as an indicator of anemia control.

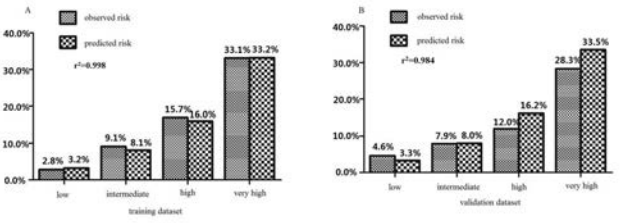
FR-PO675

Development and Validation of a Predictive Mortality Risk Score in Chinese Incident Maintenance Hemodialysis Patients Xi Yao. *Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: We aimed to predict 2-Year all-cause mortality in incident maintenance hemodialysis (MHD) patients by using available clinical and laboratory data, and to establish a risk scoring model.

Methods: Data of incident MHD patients were from Zhejiang Dialysis Quality and Management Center(ZDQM) during the period from January 2008 to June 2012. All patients were ³18 years old and survived at least 3 months after starting dialysis treatment, who were followed up for two years. Patients were randomly divided into training dataset (60%, n=2551) and validation dataset(40%, n=1744). The predictive model was developed by using a logistic regression model according to the clinical data in training dataset. The risk model were tested by using the area under the receiver operating characteristic(ROC) curve. The risk scoring model for 2-Year mortality was set up according to the coefficient and rank of variables in the risk model.

Results: In our predictive model, predictors were age, causes of end stage kidney disease(ESRD), vascular access catheter, history of cancer, serum albumin and serum total calcium.The area under the ROC curve of predictive model in training dataset was 0.767, Hosmer-Lemeshow Chi-test, P=0.925, which was highly discriminatory when applied to validation dataset(ROC 0.732), and the sensitivity and specificity were 71.5% and 64.2%, respectively. The risk scores of low, intermediate, high and very high mortality risk strata were <9, 10~13, 14~17 and ³18 points, respectively. Observed and predicted mortality risk in the training dataset and validation dataset had a significantly linear relationship(r2 = 0.998 and 0.984) across risk strata.



Conclusions: The risk-score model can accurately predict 2-Year all-cause mortality in Chinese MHD patients and external validation is needed in future.

FR-PO676

Prediction of Changes in Serum Albumin Levels Among Hemodialysis Patients by Serum Neutrophil Gelatinase-Associated Lipocalin Levels Hirotaka Imamaki,[1] Akira Ishii,[1] Hideki Yokoi,[1] Masato Kasahara,[2] Keita P. Mori,[1] Takashige Kuwabara,[1,3] Kazuwa Nakao,[4] Masashi Mukoyama,[1,3] Motoko Yanagita,[1,4] Kiyoshi Mori.[4] *[1]Dept of Nephrology, Graduate School of Medicine, Kyoto Univ, Kyoto, Japan; [2]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; [3]Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; [4]Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.*

Background: Circulating concentration of neutrophil gelatinase-associated lipocalin (NGAL or LCN2) is elevated in acute and chronic kidney diseases. Recently, we reported that, in a cross-sectional study, serum NGAL concentrations in maintenance hemodialysis (HD) patients were determined independently by % creatinine generation rate, white blood cell count and anion gap, indicating that NGAL is a marker of good nutritional conditions. Clinical impact of NGAL was further evaluated in a prospective analysis.

Methods: Correlations of baseline nutritional indices with baseline and follow-up serum albumin levels and with changes in albumin levels after a year were investigated among 87 HD patients using linear regression analysis.

Results: Follow-up albumin levels were positively correlated to baseline NGAL, albumin, geriatric nutritional risk index, creatinine, %creatinine generation rate, anion gap, choline esterase, triglyceride levels and neutrophil counts, and negatively to age. Similar findings were obtained for baseline albumin levels. Importantly, albumin increase was positively correlated to baseline NGAL ($r=0.36$, $P<0.01$) and neutrophil but negatively correlated to baseline albumin levels. Typically, some cases with hypoalbuminemia and high NGAL levels experienced elevation in serum albumin levels after recovery from infection (or inflammatory disorders). On the other hand, in some cases with preserved albumin levels and low NGAL levels, serum albumin levels decreased once severe infection developed and reduced albumin levels persisted even after recovery from infection.

Conclusions: Serum NGAL level in HD patients appears to be a unique biomarker allowing prediction of alteration in serum albumin levels in a year.

Race, Health-Related Quality of Life and Mortality in a Large Cohort of Brazilian Multiracial Hemodialysis Population Marcelo Barreto Lopes, Priscila S. Carvalho, Jéssica S. Fernandes, Raissa B. Peixoto, Pedro Guimarães Silva, Jean M. Monteiro, Gildete Barreto Lopes, Antonio Alberto Lopes. *Federal Univ of Bahia, Salvador, BA, Brazil.*

Background: Studies developed in patients undergoing maintenance hemodialysis (MHD) in the United States (US) indicate that the survival and the health-related quality of life (HRQOL) are better in African Americans and other racial minorities than in Whites. Similar to the US, Brazil is a country with a diverse racial population. There is a lack of studies to investigate if there are differences in HRQOL and mortality by race in Brazilian MHD patients. The present study developed in a multiracial Brazilian MHD population investigated associations of race (Whites as reference) with HRQOL and survival.

Methods: A prospective cohort of 1084 MHD patients (11.8% White, 61.3% mixed race and 26.8% Black) enrolled in the Prospective Study of the Prognosis of Chronic Hemodialysis Patients (PROHEMO) developed in nephrology clinics of Salvador, Brazil. The predictor variable was race (White as reference). Outcomes were mortality and HRQOL scores, using the KDQOL-SF. Multivariable linear regression was used for differences in scores and Cox regression for mortality. Associations were adjusted for age, sex, diabetes, heart failure, blood hemoglobin and vintage.

Results: Mean age was significantly lower ($P<0.001$) in Blacks (49.2±14.0 yr) and mixed races (47.6±14.5 yr) than in Whites (55.0±13.7 yr). In the multivariable linear regression, differences were not observed by race for PCS, MCS, disease burden and effects of kidney disease. For symptoms/problems, a significantly ($P=0.043$) higher adjusted score (difference=3.6) was observed in Whites (than in Blacks). In the Cox model with complete adjustment for covariates, the hazard ratio (HR) was 0.95 (95% confidence interval (CI) =0.66-1.35) for the comparison between mixed race and White and 1.10 (95% CI=0.75-1.61) for the comparison between Blacks and Whites.

Conclusions: In disagreement with studies developed in the United States, this study developed in a multiracial Brazilian hemodialysis did not show worse HRQOL and higher mortality in whites as compared with patients of mixed race and Blacks.

Low Lymphocyte Counts Are an Independent Predictor of Mortality in Chronic Hemodialysis Patients: A Retrospective Cohort Study
Dieter De Clerck, Christian L. Tielemans, Karl M. Wissing. *Nephrology, Univ Ziekenhuis Brussel, Brussels, Belgium.*

Background: Mortality in chronic hemodialysis populations remains high. Lymphopenia has been associated with increased cardiovascular risk in the general population but few data are available on the effect of low lymphocyte counts on long-term survival of hemodialysis patients.

Methods: Retrospective study of a single-center cohort of 689 hemodialysis patients using monthly laboratory results and dialysis parameters extracted from a center database and a national registry. The effect of baseline and time-changing lymphocyte counts on overall mortality was studied using the Kaplan Meier and Cox proportional hazard methods.

Results: Lymphopenia (<1200/µL) was present in approximately one third of incident hemodialysis patients and correlated with older age, lower creatinine, lower phosphorus, higher KT/V and a positive history of ischemic heart disease. Lymphopenia was not associated with classical markers of malnutrition-inflammation complex such as albumin, normalized protein catabolic rate, BMI and CRP. Baseline lymphopenia was associated with a 54 percent increase in the hazard of death (HR 1.54 (1.17 to 2.0; P=0.002)) as compared to the tertile of patients with highest lymphocyte counts. Lymphocyte counts tended to decrease during long-term follow up and their introduction as a time-changing variable further increased the HR to 2.1 (1.48 to 2.84; P<0.0001). The association remained significant in the multivariate Cox model after adjustment for age, phosphorus, creatinine, albumin, BMI, CRP, KT/V and history of ischemic heart disease.

Conclusions: Lymphopenia is highly prevalent in hemodialysis patients and is a strong predictor for patient death. The association was stronger when lymphocyte counts were considered as a time-changing variable and independent of other risk factors for patient death. Lymphopenia was not associated with markers of the malnutrition-inflammation complex (MIC) and therefore appears a useful prognostic tool in addition to classical markers such as CRP and albumin levels.

FR-PO679

Current Status of Hemodialysis in China
Li Zhang, Delong Zhao, Xueying Cao, Xiang-Mei Chen, Guangyan Cai. *Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.*

Background: In May 2010, the first nationwide, web-based prospective renal data registration platform, the Chinese Renal Data System (CNRDS) was launched in China. The purpose of this study was to determine the current status of hemodialysis in China by analyzing the data from CNRDS.

Methods: The data from CNDRS were used for dialysis cases including demographic, clinical, and laboratory data. We analyzed the data from CNRDS by the end of 2014.

Results: (1) There were 4047 domestic hemodialysis centers and 339748 survival patients were registered by the end of 2014. (2) In the 339748 patients, 58.85% were male. The average age was 54.9 years and average dialysis duration was 42.2 months. The three leading causes of ESRD were glomerulonephritis, diabetic nephropathy and hypertensive renal diseases. (3)14322 patients died in 2014, with an average age of 61.9 years and average dialysis duration of 39.7 months. The main causes of death were cardiovascular events and stroke, followed by infection and gastrointestinal bleeding. (4) In the patients, 44.1% had predialysis blood pressure less than 140/90mmHg, 55.4% had hemoglobin concentration ³100g/L and 80.3% had albumin levels ³35g/l. 39.6% had serum calcium between 2.10 and 2.50mmol/L. 34.7% had serum phosphorus between 1.13-1.78mmol/L. 53.9% had PTH between 130 and 600pg/ml.

	2011	2012	2013	2014
predialysis blood pressure (mmHg)	148±21/85±13	148±21/85±13	148±20/84±13	148±21/84±13
hemoglobin (g/L)	95±23	97±22	97±22	101±22
serum calcium (mmol/L)	2.15±0.36	2.15±0.40	2.15±0.40	2.17±0.35
serum phosphorus (mmol/L)	1.92±0.76	1.91±0.79	1.91±0.79	1.92±0.71
PTH (pg/ml)	394±452	405±459	405±459	402±455
albumin (g/L)	38±6	38±6	38±6	39±6

Conclusions: As Chinese National Health and Family Planning Commission have enhaced the basic medical security system on hemodialysis, both the population and the quality of hemodialysis have increased in recent years.

Funding: Government Support - Non-U.S.

FR-PO680

Outcomes and Quality of Care in Rural versus Urban Managed Dialysis Patients
James M. Zacharias,[1] Allison Dart,[2] Harvey M. Chochinov.[3] *[1]Dept of Medicine, Univ of Manitoba, Winnipeg, MB, Canada; [2]Dept of Pediatrics, Univ of Manitoba, Winnipeg, MB, Canada; [3]Dept of Psychiatry, Univ of Manitoba, Winnipeg, MB, Canada.*

Background: A proportion of patients are managed in remote satellite units in Manitoba, Canada. Urban nephrologists oversee all dialysis care; however family physicians (FP) co-manage patients. This study examines outcomes and quality of care indicators in rural vs.urban managed patients.

Methods: Prospectively collected clinical data from the Manitoba Renal Program and administrative health data housed at the Manitoba Centre for Health Policy were analyzed retrospectively. All adult (>18yo) incident hemodialysis patients on dialysis >90 days, from 1995 to 2010 were included. Individuals dialyzing in rural satellite units (n=510) more than 50% of the time were compared to their urban (n=2629) counterparts. Differences in cohort characteristics were analyzed at baseline as well as differences in primary care quality indicators. Regression analyses examined differences in hospitalizations and days in hospital. Cox proportional hazard models were performed to examine differences in survival.

Results: Patients in rural satellite units vs urban were younger, 58 vs 61yrs (p=0.002), but were more likely to have DM 69.4 vs 55.3% (p<0.0001), PVD 9.4 vs 4.0% (p<0.001) and IHD (MI, Angiogram or PTCA) 42.8 vs 34.2% (p=0.002). More rural patients accessed a FP at least once per year 85.7% vs 67.3% (p<0.0001) and 85.3% vs 68% (p<0.0001) had at least 25% continuity with the same FP. Despite increased FP utilization Pap smear, mammogram, DM eye exam and use of a Statin post MI were not significantly different. There were no differences in hospitalization outcomes between groups. However, survival was significantly better in the rural cohort OR 0.77 (CI 0.68-0.88, p<0.0001), after controlling for sex, income, charlson, era, age and region at the start of dialysis.

Conclusions: Survival in a cohort of patients dialyzing in remote satellite units was found to be superior to their urban counterparts, after controlling for co-morbidities. A potential reason might be increased primary care involvement, although differences were not seen in traditional quality of care indicators.

FR-PO681

Applying Hemodialysis Clinical Quality Indicators to Individual Patients: A Useful Mortality Prognostic Tool in Clinical Practice?
Tiago Assis Pereira, Artur P. Mendes. *Unidade Linda-a-velha, Diaverum, Linda-a-Velha, Oeiras, Portugal.*

Background: Hemodialysis (HD) care is routinely assessed by a set of clinical and laboratorial parameters, known as Clinical Quality Indicators (CQI). CQI registry and monitoring constitutes an instrument to evaluate the quality of care provided at each HD Unit. The purpose of this study was to determine whether CQI, applied on an individual patient basis, is a predictor of mortality.

Methods: Retrospective study that included 334 patients of a HD Unit from 2011 to 2014. Demographic, clinical and laboratories data were collected. The CQI considered were eleven, whose intended target were: spKt/V ≥ 1.4; weekly dialysis time ≥ 720 minutes; Albumin ≥ 3.5 g/dL; Hemoglobin between 10 and 12 g/dL; phosphatemia between 2.5 and 5.5 mg/dL; CaxP product < 55 mg^2/dL^2; PTH levels between 150 and 600 pg/ml; Ferritin between 200 and 800 mg/dL; Mean arterial pressure < 105 mmHg; interdialytic weight gain (IWG) < 4% and fistulae as vascular access. Single CQI were rated in a binary form (0 = not reached target/1 = reached target) at each monthly evaluation and the average were determined. Ultimately, the eleven parameters were added in a single variable for each patient (CQIp).

Results: During follow-up, 33% of patients died. In the Cox regression model, age (HR 1.09; CI 1.07-1.11; p <0.001), diabetes (HR 2.88; CI 1.92-4.32; p <0.001), peripheral arterial disease (HR 1.63; CI 1.09-2.44; p = 0.016) and CQIp (HR 0.73; CI 0.62-0.87; p <0.001) were shown to be independent predictors of mortality, after adjustment for other clinical and demographical factors. When CQIp was replaced by its constituent variables, albumin (HR 0.016; CI 0.08 -0.32; p <0.001), PTH (HR 2.8; CI 1.10-3.93; p = 0.023), IWG (HR 0.34; CI 0.14-0.83; p = 0.018) and fistulae presence (HR 0.61, CI 0.4-0.93, p = 0.021) presented statistical significance.

Conclusions: A set of parameters, generally applied as a quality care indicators, proved to be an independent predictor of death when applied to individual patients. This should be regarded as an easy and practical prognostic tool to be applied in current practice.

FR-PO682

Association of Estimated Glomerular Filtration Rate at Commencement of Maintainence Dialysis with Mortality Among Patients with Advanced Chronic Kidney Disease in Singapore
Tazeen H. Jafar,[1] Jin Ai Zhen,[2] John C. Allen,[1] Saeideh Tavajoh,[1] Khuan yew Chow.[1] *[1]Duke-NUS Graduate Medical School Singapore; [2]National Disease Registry Office, Health Promotion Board, Singapore.*

Background: Recent evidence suggest that higher estimated glomerular filtration rate (eGFR) at commencement of dialysis may be associated with increased mortality. However, there is scarcity of data on patients of Southeast Asian origin. We analyzed and compared mortality risk in patients with early and late start dialysis as measured by kidney function at dialysis initiation among Southeast Asian population of Singapore.

Methods: We performed a retrospective analysis of patients enrolled in the Singapore Renal Data system database from 2008 to 2011. Patients were classified into groups by eGFR at dialysis initiation.

Results: In this total incident population (n=3708), a total of 1510 individuals died during a median follow-up period of 2.8 years. The hazard ratio (HR) and 95% CI associated with different levels of eGFR at commencement of RRT are shown in table below. The main multivariable model (n=3189 without missing information on covariates) associated with the eGFR at dialysis initiation within the groups: age, gender, level of education, smoking, presence of diabetes, ischemic heart disease, cerebrovascular disease, and peripheral vascular disease, malignancy, hepatitis B, hepatitis C, kidney transplant, and modality of dialysis. Additional models accounted for serum albumin (n=2657) , and serum ferritin (n=2462), and serum calcium (n=1628).

eGFR ml/min/1.73m2	Dialysis Patients N=3189	Deaths	Adjusted HR (95%CI)	p trend
<5	1345	395	1.00	<0.0001
5-10	1541	656	1.19 (1.04-1.36)	
>10	303	180	1.81 (1.49-2.19)	

The results were consistent after accounting for serum albumin, serum ferritin, and serum calcium in the multivariable models.

Conclusions: Late initiation of dialysis is associated with a lower risk of mortality in comparison with early dialysis initiation in Southeast Asians in Singapore.

FR-PO683

Predicting Mortality for Patients Who Are on Hemodialysis–A National Cohort Study in Taiwan Jinn-Yang Chen. *Div of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Comorbid conditions and medical history provide prognostic information for dialysis patients. The objective of this study was to develop a prognostic model to predict short-term (6-months and 1-year) and long-term (2.5-years) survival for incident hemodialysis (HD) patients.

Methods: Incident Taiwanese hemodialysis patients from 2006 to 2010 were extracted from National Health Insurance claim records. Prognostic model was developed by using comorbid conditions (summaried as Taiwan index), monthly income and medical history during one year before initiation of dialysis. Somer's D statistic was used to assess the discrimination ability of our model.

Results: A total of 36,875 incidence HD patients were included in this study and the last followed-up day was December 31, 2011. More comorbid burden, male gender, history of acute kidney injury, dementia, admitting to intensive care unit, staying at nursing home and ever using ventilator were significant prognostic factors. Monthly income only had marginal effects on survival at 2.5 years. For discrimination ability, our model has Somer's D statistics of 0.76, 0.76, and 0.75 for 6-months, 1-year, and 2.5-years survival, respectively.

Conclusions: Three prognostic models with same covariates for short-term and long-term survival in HD patients were found in this study. The consistency in model performance helps clinicians and patients to make decision.

Funding: Government Support - Non-U.S.

FR-PO684

Twice Weekly Treatment Eligibility for Incident Hemodialysis (HD) Patients Suresh Appasamy, Andrew I. Chin, Thomas A. Depner. *Div of Nephrology, Univ of California, Davis, Sacramento, CA.*

Background: KDOQI guidelines advise that hemodialysis treatments constitute a patient burden and a risk to native kidney function that can be lowered by reducing HD frequency from 3 to 2/week in patients with substantial residual kidney function. To determine eligibility for twice weekly HD we analyzed 24 hour residual urea clearances (Kru) and volume removal requirements in all incident patients with urine output >100 ml/day in 4 HD centers.

Methods: From the years 2000-2014, 420 out of 734 incident patients who survived ≥6 mos, starting HD 3/week had Kru measurements within 1-3 months after starting HD. The fractional weekly renal clearance (KrT/V) was subtracted from the continuous equivalent minimum goal stdKT/V of 2.0 volumes/week to determine the minimum required standard dialyzer clearance (stdKdT/V). With N set as 2/week, eKT/V was back-calculated from the Leypoldt equation for stdKT/V, spKT/V from the Tattersall equation for eKT/V, and Kd from modeled V and T that was limited to a maximum of 4 hours. Patients were excluded if the ultrafiltration (Uf) rate needed to control volume was >10 ml/kg/hr, MAP dropped >10 mm, or the patient exhibited symptoms of nausea, vomiting, or cramps.

Results: Patients: N=420, age 57±15 yrs, 58% male, 51% diabetic, 66% TD Catheters. Urine collections: 974±617 mL, Kru 3.0±2.1 mL/min, KrT/V 0.7±0.5. Uf 2.1±1.2 L/dialysis (3x/week), 2.8±1.6% of dry weight.

Eligibility target for 2/week HD	Patients achieving target
spKT/V <1.4 per 4 hour HD	225 (54%)
Uf rate ≤ 10 mL/kg/hr	206 (49%)
MAP drop < 10 mmHg	343 (82%)
Dialysis symptoms < 10 per month	407 (97%)

In the 225 patients who could achieve the target stdKT/V with 2/week HD, the mean spKT/V required was 0.83±0.36. A total of 105 or 25% of patients with measured Kru met all 4 criteria.

Conclusions: Urine collections disclosed that 225 or approximately 30% of 734 incident patients were eligible for 2/week HD based on solute kinetics alone. Using conservative criteria, half of these were judged ineligible because of Uf requirements or HD-induced symptoms. Opportunity exists for incremental HD in a significant number of incident patients.

FR-PO685

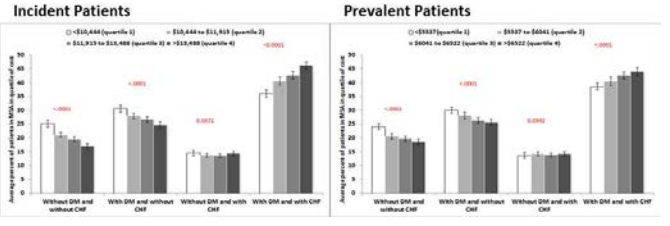
The Relationship of Diabetes and Congestive Heart Failure to Costs of Care in End Stage Renal Disease Patients Sheetal Chaudhuri, Jane Brzozowski, Hao Han, Len A. Usvyat, John W. Larkin, Mahathi Mothali, Terry Ketchersid, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Many Medicare patients (Pts) with end stage renal disease (ESRD) are known to have co-morbidities of diabetes mellitus (DM) and/or congestive heart failure (CHF). Total costs of care for ESRD Pts are likely to be dependent on patient comorbidities and likely to vary by geography. We investigated the relationship of DM and CHF based on Pts' geographic location.

Methods: ESRD Pts with evidence of dialysis at any time during Jan 1, 2010 through Dec 31, 2011 and Medicare as their primary payer were analyzed. Pts were stratified based on Metropolitan Statistical Areas (MSA) and Medicare Part A and B costs were calculated from 100% Medicare data. T-test comparisons were performed for quartiles of total cost of care for eight groups: based on vintage (incident [<90 days on dialysis] or prevalent [>3 years on dialysis]), as well as, comorbidities (no DM and no CHF, with DM and no CHF, no DM and with CHF and with both DM and CHF).

Results: Claims for 107,659 Pts were analyzed. Total cost of care increased significantly as the percent (%) of Pts with CHF and DM increased; cost of care declined significantly as the % of Pts with neither DM nor CHF increased by MSA. Cost of care did not change with the increase in % of Pts without DM and with CHF. Yet, costs of care declined as % of Pts with DM and without CHF increased by MSA. These patterns were observed in both incident and prevalent Pts.

Figure 1. Costs of care by MSA (per member per month)



Conclusions: These results identify differences in association between ESRD related co-morbidities and total costs of care: the % of Pts with both DM and CHF is higher in areas with higher total costs. Surprisingly, costs of care are lower in areas where the % of Pts with DM but without CHF is higher. Risk Adjustments should be considered.

FR-PO686

Long Term Outcomes Over 2 Years following a Dialysis Adequacy Quality Improvement Initiative Sajeda Youssouf,[1,2] Philip A. Kalra,[1,2] Janet Hegarty.[1,2] *[1]Salford Royal NHS Foundation Trust; [2]Manchester Academic Health Sciences Centre.*

Background: Dialysis adequacy is known to correlate with clinical outcomes such as mortality. Evidence based guidelines recommend that haemodialysis patients should achieve a urea reduction ratio of >65%. UK Renal Registry data shows wide variation in facility attainment of target URR. In 2010 the Salford Renal Network implemented an ambitious programme to uplift attainment of key quality of care indicators to within the top 10% in the UK; dialysis adequacy was a target in 2 phases of improvement in 2010-2012.

Methods: Our network implemented a quality improvement programme using collaborative methodology. We set four teams a different clinical indicator to work on over 12 month cycles for 2 successive years, guided by QI facilitation input. Unit A worked on URR in phase 1 and developed a package of changes using plan-do-study-act (PDSA) testing that was used for improvement by Unit B in phase 2. We analysed the long-term outcomes in these units for a further 2 years until May 2014.

Results: Both units reached their aim of >90% of patients achieving target URR>65% within their improvement year. Both units sustained the improvements for 2 years with no additional resource input after the collaborative. Changes included protocolised nurse-led changes to dialysis prescriptions, multidisciplinary review of vascular access, a nurse-led anticoagulation protocol, blood sampling protocol, and monthly reports.

	Pre-intervention	Post-intevention	Outcome at 2 years	p value
Percentage of patients with URR > 65% Unit A	75.8%	91.4%	97.8%	0.003
Mean URR, % (SD) Unit A	70.3 ± 8.3	74.5 ± 5.5	74.9 ± 4.9	0.002
Percentage of patients with URR > 65% Unit B	68.9%	91.1%	93.0%	0.002
Mean URR, % (SD) Unit B	69.4 ± 9.1	72.9 ± 9.2	72.8 ± 5.9	0.003

Conclusions: Longer term outcomes from QI interventions are underreported with limited evidence on sustainability. We implemented multifaceted interventions to improve dialysis adequacy in our network to within the top 10% in the UK. Implementing evidence-based changes led by frontline staff trained in QI has sustained these improvements for 2 years after a formal QI intervention, improving quality of care for our patients.

FR-PO687

Clinical Effectiveness of Intermittent Infusion Hemodiafiltration (I-HDF) Compared with Conventional Hemodialysis: A Multicenter Clinical Trial

Michio Mineshima, Kei Eguchi. *Clinical Engineering, Tokyo Women's Medical Univ, Tokyo, Japan.*

Background: Intermittent infusion hemodiafiltration (I-HDF) using backfiltration of an ultrapure dialysis fluid has been developed to improve the peripheral circulation of the patient receiving a typical hemodialysis (HD) with repeated intermittent infusion by an automated dialysis machine, GC-110N (JMS Co. Ltd., Tokyo, Japan). In a typical HD treatment, excessive water removal often induces hypotension and muscle spasm. In the I-HDF, some 200-300 mL of ultrapure dialysis fluid was infused into the blood component through the dialysis membrane at a rate of 100 mL/min, every 30 min. I-HDF, namely, means a HDF treatment with small amount of infusion volume, 1.4 to 2.1 L(= 200-300 mL x 7 times)/session.

Methods: In this paper, clinical effectiveness of I-HDF was evaluated in comparison with conventional HD (CHD) during a multi-center clinical trial that twenty chronic renal disease patients participated.

Results: A significantly lower value for time-averaged blood volume reduction was obtained with I-HDF compared with CHD in spite of there being no difference in the total amount of water removal. It was due to a higher plasma refilling rate in I-HDF. In addition, increasing peripheral blood flow rate in the patient's toe was detected by a laser flowmeter for each infusion in many patients. The cleared space value defined as amount of normalized solute removal during a treatment were higher with I-HDF than CHD for inorganic phosphate and α 1-MG. Moderate α 1-MG clearance reduction was found in I-HDF due to the prevention of membrane fouling by intermittent backfiltration of the dialysis fluid. No significant difference of albumin leakage between I-HDF and CHD. Reduction ratio of the systolic blood pressure and the number of treatments by medical staff in I-HDF were lower than those in CHD.

Conclusions: Intermittent Infusion HDF using an automated dialysis machine was effective for improvement of the peripheral circulation of patients receiving conventional HD.

FR-PO688

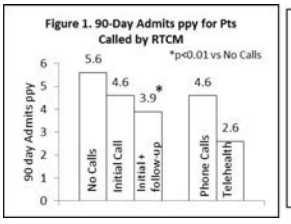
Impact of Post-Hospital Phone and Telehealth Case Management to Reduce Admissions in Hemodialysis Patients

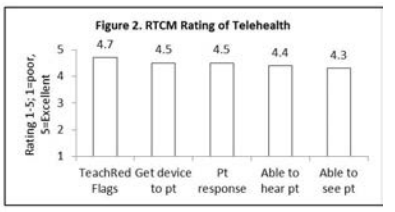
Rebecca L. Wingard,[1] Billie Axley,[1] Kathryn A. McDougall,[1] Andrew D. Howard,[2] Joelle Heilemann,[1] Fern Parlier,[1] Sophia Rosen,[1] Len A. Usvyat,[1] Alexis Porras,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Metropolitan Nephrology Associates, Clinton, MD.*

Background: 2012 30-day readmissions for hemodialysis (HD) patients (pts) were high at 35% (USRDS). Right TraC™ (RT) used post-hospital RT case manager (RTCM) calls to reduce post-hospital admissions. Telehealth vs. phone calls was also studied.

Methods: In 28 clinics from Feb-Nov '14, RTCMs attempted weekly phone calls to pts at home or dialysis clinic, or via telehealth in the clinic for 30 days post-hospital. RTCMs assisted pts with discharge instructions and addressed changes in dry weight, medications, nutrition, access, and taught Red Flags (symptoms that signal potential readmission). Telehealth was performed via iPad tablet in the clinic, configured for secure video tele-communication using clinic's local wifi. 90-day admit rates post-hospital adjusted for comorbidities and RTCM telehealth ratings were measured; comparison was done using Poisson models.

Results: For pts with no RTCM calls (n=1702) vs. pts with initial call (n= 801), annualized 90-day admits per pt year (ppy) were 5.6 and 4.6, respectively (p=0.89, Fig 1). 90-day admits ppy for pts with initial call and >= 1 follow-up call (n=591) were 3.9 (p=0.0025 vs. no calls). For pts with initial call by phone (n=785) vs telehealth (n=34), 90-day admits ppy were 4.6 and 2.6, respectively (p=0.47). RTCM telehealth ratings ranged 4.3-4.7, and cited enhanced pt-RTCM relationship and assessment (Fig 2). "Able to see pt" rated lowest, due to wifi connectivity.





Conclusions: RTCM calls during 30 days post-hospital showed significantly lower 90-day admits ppy for pts with initial and >=1 follow-up call. Telehealth had lower 90-day admits ppy vs. phone calls, although not significant. Further study is needed, especially in view of high RTCM ratings.

FR-PO689

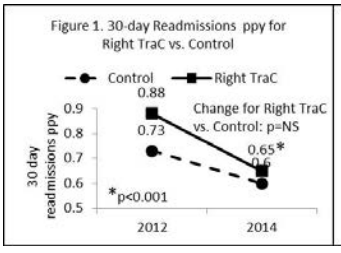
Reduced Hemodialysis (HD) Patient Hospital Admissions and Readmissions Associated with Right TraC™ Care Transitions Program

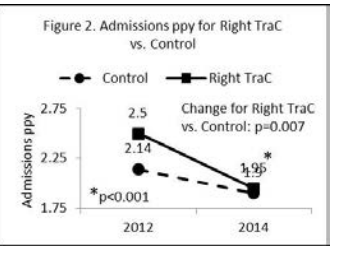
Rebecca L. Wingard,[1] Billie Axley,[1] Kathryn A. McDougall,[1] Andrew D. Howard,[2] Cathleen Okeefe,[1] Sharon Deluca,[1] Janice B. Sitzlar,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care, Waltham, MA; [2]Metropolitan Nephrology Associates, Clinton, MD.*

Background: 30-day readmissions for HD patients (pts) are high at 35% in 2012 (USRDS). The Right TraC (RT) Program addressed factors in the complex process of care transitions, with the aim to reduce hospital admissions and readmissions.

Methods: 26 HD clinics (3682 pts) were in RT. Interventions deployed in 3 phases (Apr '13-Nov '14). I: Pre- and post-hospital checklists for clinics to manage pt teaching, anemia, nutrition, medications, and dry weight. II: Telephonic case management for 30 days post-discharge. III: Dialysis Link™ centralized clinical info exchange among providers. Admission and readmission rates per pt year (ppy) for "baseline year" (2012) vs. "full intervention year" (2014) were compared to 18 control clinics (2449 pts) matched for clinic size, admission and readmission rate, and urban vs. rural location at baseline. Poisson models with random effects for pt and clinic, adjusted for age, vintage, race, gender, ethnicity, DM, CHF, and COPD were constructed to assess the difference between baseline and intervention and between RT and control clinics.

Results: 30-day readmissions ppy declined from baseline to full intervention year in RT (0.88 to 0.65, p<0.001) and controls (0.73 to 0.6, p=NS); comparison of the change between groups was not significant (Fig 1). Admissions ppy declined from 2.5 to 1.95 for RT (p<0.001), and 2.14 to 1.9 for controls (p=NS); comparison of the change between groups was significant with greater decline for RT (p<0.001, Fig 2).





Conclusions: RT interventions were associated with significant declines in admissions and 30-day readmissions. The difference in the changes between RT vs. controls was significant for admissions, but not significant for 30-day readmissions.

FR-PO690

Predicting Early Mortality Among Hemodialysis Patients Using USRDS Data

Fang Wang,[1,2] Zhi He,[3] Jennifer L. Bragg-Gresham,[1] Yuan Yang,[3] Haoyu Gu,[3] Yi Li,[3] Kamyar Kalantar-Zadeh,[4] Elani Streja,[5] Rajiv Saran.[1] *[1]Div of Nephrology-Dept of Internal Medicine and KECC, Univ of Michigan, Ann Arbor, MI; [2]Renal Div Dept of Medicine, Peking Univ First Hospital, Beijing, China; [3]Dept of Biostatistics and KECC, Univ of Michigan, Ann Arbor, MI; [4]Univ of California Irvine, Orange, CA; [5]Harold Simmons Center, Orange, CA.*

Background: Higher early mortality of hemodialysis (HD) is recognized. We sought to quantify the risk of early mortality and develop a robust prediction model which could potentially guide clinical decision-making.

Methods: The 2007-2012 data from the United States Renal Data System (USRDS) on incident HD patients, age >18 years, were randomly split as 'training' and 'validation' samples. Cox proportional hazards model with piece-wise constant coefficients was used to model all-cause mortality during day 0-90 and day 91-365 of HD. Those transferred to peritoneal dialysis or transplantation were censored. The resulting model was validated by C statistic.

Results: The mean age (n=611,094) was 63.6±14.9 years, with 130,473 deaths during the first year of HD. Mortality rates were 35 per 100 person-years in the first 90 days and 21 per 100 person-years during day 91-365. The prediction equation for early mortality involved 23 variables including demographics characteristics, pre-ESRD care, laboratory values, co-morbidities as well as institutionalization status. In adjusted analyses, selected variables with significant time-varying effects are listed in the Table.

Table: Hazard ratios for death in the first year of HD

Measures	Adjusted HR (95%CI) Day 0-90	Day 91-365	Interaction between time period and individual effect (P value)
ESRD caused by ATN	1.15(1.10-1.19)	0.98 (0.97-1.02)	<0.001
History of diabetes	0.91(0.89-0.93)	1.05 (1.03-1.07)	<0.001
Pre-ESRD care 0-5 months	1.52(1.48-1.56)	1.26 (1.23-1.29)	<0.001
6-12 months	1.20(1.17-1.24)	1.12 (1.09-1.15)	<0.001
>12 months	1.00 (as ref)	1.00 (as ref)	
Alcohol dependence	1.95(1.85-2.06)	1.26 (1.20-1.33)	<0.001
Serum albumin <3g/dL	1.53(1.50-1.56)	1.31 (1.29-1.36)	<0.001

The model was adjusted for age, sex, race, BMI, vascular access, institutionalization, comorbidities including cardiovascular disease, hypertension, cancer and anemia.

The prediction model reached a C statistic of 0.70 (95% CI, 0.57-0.82).

Conclusions: We have developed a predictive model for early mortality in a national cohort of incident HD patients and identified risk factors with time-varying effects. We intend to further refine and validate this model before recommending in clinical practice.

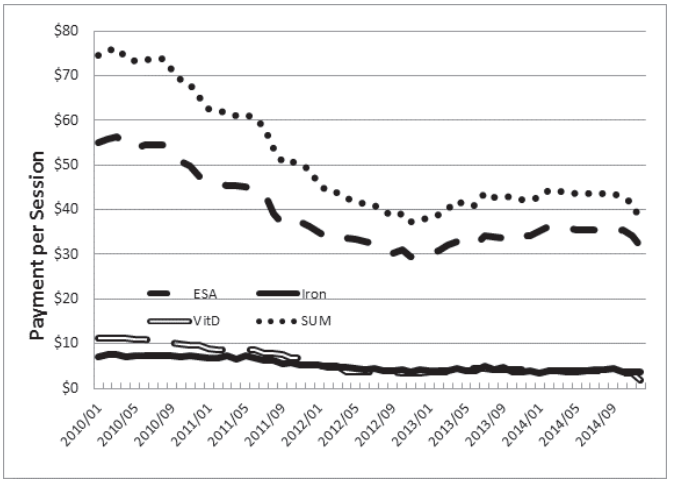
Recent Evidence on the Impact of Medicare's Bundled, Prospective Payment System for Renal Dialysis Richard Hirth,[1] Tammie A. Nahra,[1] Adam S. Wilk,[1] Marc Turenne,[2] John Wheeler,[1] Kathryn Sleeman,[1] Wei Zhang,[1] Jonathan H. Segal.[1] *[1]Univ of Michigan; [2]Arbor Research Collaborative for Health.*

Background: Medicare implemented an expanded prospective payment system (PPS) in 2011, including services previously paid by fee-for-service. One intent of the PPS was to incentivize providers to be more efficient in the mix of services provided.

Methods: We used Medicare claims to assess monthly trends from 1/2010-12/2014 for injectable drugs that were previously billed separately. For 2010, we assessed actual spending. For 2011-14, we projected spending based on reported utilization.

Results: ESA use declined in the months immediately pre- and post-PPS, continuing to decline through 2012. In 2013, ESA use leveled off. Use of iron products, often improving the efficacy of ESAs, increased through 2011 and then began to decline. Total drug cost, including ESAs, iron, and vitamin D, fell by more than 50%, from a high of $76.16 per session in early 2010 to a low of $37.67 toward the end of 2012. This decline was driven by reduced drug utilization. Since early 2013, total drug costs have risen a bit due to higher drug prices. Beginning in 2013, drug costs have remained at about $42 per session, reflecting gently declining use and higher drug prices.[Fig.1] The reduction in drug spending of about $34 per session over a period of 4 years exceeds the Medicare mandated reduction in the base rate over the same period.



Conclusions: The expanded bundle dialysis PPS provided incentives for both lower medication utilization overall and the use of lower cost therapies. These incentives seem to have motivated an immediate movement toward lower cost methods of care. Facilities have been able to maintain a lower cost of care over the last two years. CMS continues to monitor facility costs and will continue to make a reduction to the ESRD PPS Market Basket through CY 2018, in accordance with section 217 of PAMA.

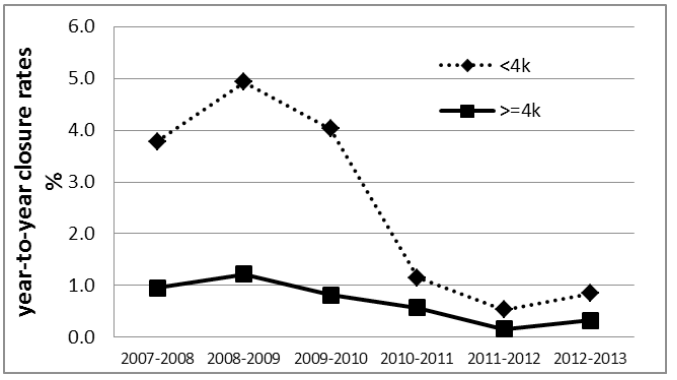
FR-PO692

Effect of Medicare's Payment Adjustment for Low-Volume Dialysis Facilities on Facility Closures Richard Hirth,[1] Tammie A. Nahra,[1] Adam S. Wilk,[1] Marc Turenne,[2] Jonathan H. Segal,[1] John Wheeler,[1] Kathryn Sleeman,[1] Wei Zhang.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Small dialysis facilities may face higher per-treatment costs due to economies of scale. Since 2011 a low-volume payment adjustment (LVPA) raised Medicare payments 18.9% to facilities with <4,000 treatments in each of the 3 prior calendar years. A goal of this policy is to preserve access to care by preventing the closure of small facilities.

Methods: We tested the hypothesis that the LVPA prevented closures by examining the year-to-year closure rates of U.S. dialysis facilities during 2007-2013, before and after the policy, comparing facilities providing <4000 and >4000 annual treatments. Analyses with linear regression relate facility outcomes to prior year size, ownership, for-profit status, hospital affiliation, patient mix, rural location, modality mix and county characteristics, to examine the effect of the LVPA on # of treatments provided by facilities.

Results: Among low-volume facilities, year-to-year closure rates were 3.8%, 4.9% and 4.0% pre-LVPA, falling to 1.1%, 0.5% and 0.8% post-LVPA. Among facilities with >4000 treatments, closure rates also decreased, but to a much smaller extent (from 1.0%, 1.2% and 0.8% pre-LVPA to 0.6%, 0.2% and 0.3% post-LVPA).



Conclusions: In Medicare's bundled payment system, closure rates decreased overall, with a much larger absolute reduction among small facilities. The gap in closure rates between small and large facilities fell from about 3% points before the policy to about 0.5% points after. LVPA appears to have helped prevent small dialysis facility closures, but it may also motivate some small facilities to avoid growing in order to retain the LVPA. Emphasizing a dialysis facility's importance for patient access rather than size alone may help inform payment policy modifications.

FR-PO693

Delayed Thrombectomy Increases Risk for Dialysis Catheter Placement Scott Reule, Sunil Akkina, Andrew J. Esten, Paul E. Drawz. *Dept of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Arteriovenous dialysis accesses (fistulas or grafts) are associated with significant rates of thrombosis. Though timely thrombectomy may have a significant impact on immediate and long-term access survival, it is not always readily available. The goal of this study was to evaluate whether delayed thrombectomy increases risk for loss of dialysis access and subsequent placement of a dialysis catheter.

Methods: All patients at the Fairview Health System with thrombectomy as the primary reason for admission between January 2008 and April 2015 were included in this retrospective observational study. The electronic medical record was reviewed to evaluate type of access, timing of admission and declot, and access on discharge and 6 and 12 months after discharge. Baseline characteristics and proportions were determined for the overall population as well as stratified by tertile of time to thrombectomy, defined as the time from admission to the declot procedure. The outcomes of interest included need for dialysis catheter at discharge and 6 and 12 months after discharge. Logistic regression was used to evaluate the risk for dialysis catheter use adjusting for prior intervention, access type, and time to thrombectomy.

Results: Of 444 patients identified using procedural codes, 122 were admitted primarily for thrombectomy. The mean age was 60.4 years, 65% were male, and 44.3% utilized arteriovenous fistula for access. Mean time to thrombectomy was 0.45 days (range: 0.05-1.13 days). Fifteen patients utilized a catheter for hemodialysis on discharge. Delayed thrombectomy was associated with a two-fold increase in requirement for catheter at discharge (OR 2.02; CI 1.19-3.43) and at 6 months (OR 2.04; CI 1.20-3.48). This association remained present at 12 months (OR 1.75; CI 1.02-3.00).

Conclusions: In this study of patients cared for within a large academic health system, a one day delay in thrombectomy doubled the risk for need for a dialysis catheter at discharge and 6 and 12 months after discharge. These results indicate that a clotted dialysis access should be considered a medical emergency.

FR-PO694

Intradialytic Body Weight Reduction and Outcome of Vascular Access: Analyses of Data from the Japan Dialysis Outcomes and Practice Patterns Study (J-DOPPS) Manabu Asano,[1] Kenichi Oguchi,[1] Akira Saito,[2] Yoshihiro Onishi,[3] Yosuke Yamamoto,[4] Shunichi Fukuhara,[2] Takashi Akiba,[2] Tadao Akizawa.[2] *[1]Bosei Hospital, Saitama, Japan; [2]J-DOPPS Research Group, Japan; [3]iHope International, Kyoto, Japan; [4]Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan.*

Background: There is no doubt that large-volume ultrafiltration is one of the important risk factors for vascular access (VA) thrombus in hemodialysis patients. However, the relationships between intradialytic body weight reduction and VA patency are still in the middle of being discussed. We tried to determine whether large-volume ultrafiltration was practically associated with VA failure by means of the results obtained from the phase 3 and 4 J-DOPPS.

Methods: Referring data from the phase 3 and 4 J-DOPPS, the current analyses were limited to 2736 patients who were evaluable for VA patency and body weight change during dialysis. They were assigned to one of the following three groups according to the tertiles (T1-T3) of intradialytic fluid removal per body weight: T1, -9.5% to 3.8%; T2, 3.8% to 5.1%; and T3, 5.1% to 13.7%. The hazard ratio of VA failure was compared across these tertile groups using Cox regression models. The models were adjusted for the following risk factors: age, gender, BMI, diabetes, hemoglobin, phosphorus, Kt/V, ESA use, and antiplatelets use. Primary VA survival was defined as the days until the first VA intervention. Secondary VA survival was defined as the days until new VA creation.

Results: The incidence rates (events/100 person-years) of primary and secondary VA events were 4.7 and 1.3 for T1, 5.6 and 1.6 for T2, and 6.7 and 1.7 for T3, respectively. The adjusted hazard ratios versus T1 for primary VA patency were 1.16 (95% confidence interval [CI], 0.88 to 1.52) for T2 and 1.41 (95% CI, 1.07 to 1.87) for T3. The hazard ratios versus T1 for secondary VA patency were 1.29 (95% CI, 0.78 to 2.13) for T2 and 1.45 (95% CI, 0.86 to 2.45) for T3.

Conclusions: This study shows that large-volume ultrafiltration during dialysis tends to increase VA failure in hemodialysis patients.

FR-PO695

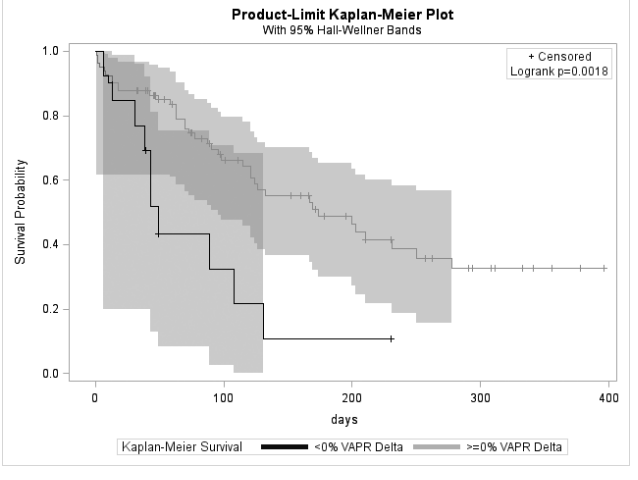
Post-Endovascular Intervention Venous Access Pressure Ratio (VAPR) Predicts Access Survival Lalathaksha Murthy Kumbar,[1] Gerard Zasuwa,[1] Anatole Besarab,[2] Kim Hirschman,[3] Jerry Yee.[1] *[1]Henry Ford Hospital, Detroit, MI; [2]Stanford, Palo Alto, CA; [3]Vasc-Alert, LLC, Evanston, IL.*

Background: The Vascular access pressure ratio test identifies vascular access (VA) dysfunction in hemodialysis patients when 3 consecutive VAPR (VAP/MAP) measurements are >0.55. We hypothesized whether a post-interventional VAPR decline predicts VA outcomes in patients with VA dysfunction.

Methods: Retrospective analysis of all VA procedures from 09/2013 to 04/2015. Data collection included demographics, comorbidities, VA features, mean VAPR <30 days pre- and post-procedure, time-to-next procedure, and access patency. Kaplan-Meier arteriovenous graft (AVG) and fistula (AVF) survival curves were compared by the log-rank test. A Cox-proportional hazard model was used to determine the association of VAPR Δ% (Pre-Post)/Pre×100%) with access survival.

Results: Analysis of 92 subjects [females 57% (n=53); black 88%; and diabetes mellitus 61% (n=56)] included 46 AVF with 94 procedures and 46 AVG with 86 procedures. Mean VAPR Δ% was 26 ± 61 (SD) and 16 ± 54 for AVF and AVG, respectively. VAPR decline was absent in 13 AVF. AVF with no VAPR decline (<0%) post-intervention when compared to AVF with any decline (>0%) required more subsequent procedures (64% vs 47%), with fewer days to next procedure (75 vs 149 d), and lower survival (p=0.002). For AVG, a post-intervention VAPR decline >10% (p=.04) projected AVG survival. 34% of AVG procedures had <10% decline (n=30) and required more subsequent procedures than AVG with >10% decline (64% vs 39%). AVF without VAPR decline had a 3-fold greater risk of failure (p=0.003). The risk of failure was 2.0-fold greater (p=0.04) for AVG with <10% decline.

Conclusions: A >10% post-intervention reduction of VAPR in AVG and any VAPR reduction in AVF predicts greater VA survival.



FR-PO696

Abnormalities in Mineral Metabolism and Dialysis Arteriovenous Fistula Thrombosis in the HEMO Study Anna Jeanette Jovanovich,[1,2] Eugene J. Nuccio,[2] Alfred K. Cheung,[3,4] Tom Greene,[4] Michel Chonchol.[2] *[1]Denver VA Medical Center; [2]Unversity of Colorado Denver; [3]VA Salt Lake City; [4]Univ of Utah.*

Background: Vitamin D deficiency and fibroblast growth factor 23 (FGF23) excess are highly prevalent among patients requiring chronic hemodialysis. This study aims to determine the association of 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D ($1,25(OH)_2D$), and FGF23 serum levels with arteriovenous fistula (AVF) thrombosis in hemodialysis patients.

Methods: The HEMO Study was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum 25(OH)D, $1,25(OH)_2D$, and intact FGF23 levelswere measured in stored serum samples obtained at baseline in 881 patients in this cohort.Cox proportional-hazards models were used to examine the association of 25(OH)D), $1,25(OH)_2D$, and FGF23 serum levels with time to first AVF clotting event after controlling for important clinical covariates in the HEMO Study.

Results: Patients had a mean age of 57±14 years, 55% were females, and 46% were white. During a median follow-up of 3.0 years, 111 AVF clotted. Median (IQR) serum 25(OH)D, $1,25(OH)_2D$, and FGF23 levels were 19.1 [14.2, 26.6] ng/mL, 6.3 [2.9, 14.5] pg/mL, and 3118 [726, 12928] pg/mL. Among patients with levels in the highest tertiles compared to the lowest tertile, both $1,25(OH)_2D$ and FGF23 were significantly associated with an increased risk of clotting in adjusted analyses, hazard ratio (HR) 2.79 (95% CI, 1.21-6.46) and HR 1.35 (95% CI, 1.002-1.83), respectively. No statistically significant associations were observed between 25(OH)D serum levels and AVF thrombosis.

Conclusions: Calcitriol and FGF23 excess were associated with an increased risk of AVF thrombosis among chronic hemodialysis patients.

Funding: NIDDK Support, Veterans Administration Support

FR-PO697

Ultrasound-Guided Evaluation of New AV Fistulas Safely Decreases Time to First Cannulation Farzin Farpour,[1,2] Roshan A. Patel,[1,2] George N. Coritsidis.[1,2] *[1]Nephrology, Elmhurst Hospital, Icahn School of Medicine at Mount Sinai, Elmhurst, NY; [2]Nephrology, Broadway Atlantic Dialysis Center, Elmhurst, NY.*

Background: The use of bedside ultrasonography (USG) in various medical specialties has exploded over the last decade. For the past year, we have been using bedside USG for earlier AV fistula utilization and for diagnosing potential problems. Prior to the use of USG, cannulation was based on physical exam. We were interested to see whether use of bedside USG helps in early cannulation of AVF.

Methods: USG procedures from February 2014 to February 2015 were reviewed. Time to cannulation in the year prior to the introduction of USG (2013 - 2014) was calculated and compared to similar data with USG use. By week 4 all new fistulas underwent the first USG exam.Examinations were performed by the renal attendings and fellows each exam lasting about 5 minutes. SonoSite M- Turbo ultrasound machine was used.

Results: Total of 44 USG examinations were performed on 14 patients while monitoring new AVF maturation. In 10 patients USG-guided cannulation occurred at an average of 6.2 ± 0.9 weeks compare to 10.2 ± 0.9 weeks prior to USG use (P=0.006). There were no complications seen with the earlier USG-guided cannulations. Subsequent cannulations by the nursing staff were successful without USG. In 4 patients failure of maturation was diagnosed by USG at an average of 3.8 ±0.9 weeks vs 9.6 ±1.2 weeks prior to USG (P=0.08). Antibiotic dosing occurred 21 times prior to USG compared to 11 times with USG, despite the similar catheter rates for both years.

USG image of mature fistula at 4 weeks

USG image of non-maturing fistula at 4 wee

Conclusions: USG use facilitates early AVF cannulation with decreased time to first use. Identification of potential AVF issues and their referral are accomplished earlier. This may translate to earlier catheter removal and fewer infections.

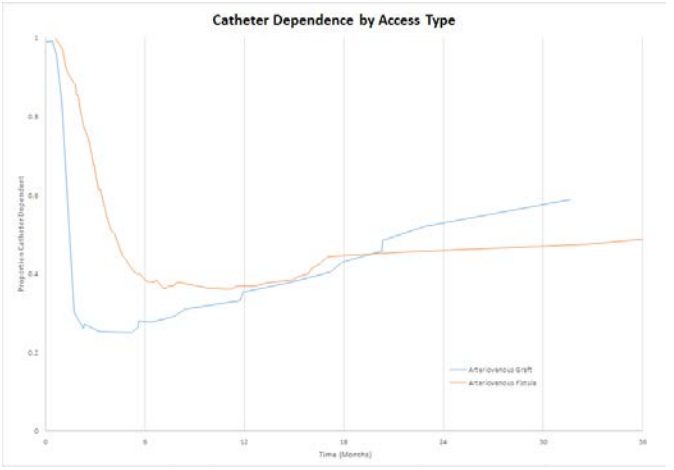
FR-PO698

Arteriovenous Grafts Reduce Catheter Dependence in the Elderly Thomas M. Loh, Matthew E. Bennett, Francis E. Loh, Eric K. Peden. *Vascular Surgery, Houston Methodist, Houston, TX.*

Background: Arteriovenous fistulas (AVF) are the permanent access of choice. The benefits of AVF, durability and longevity, are minimized in the elderly where more than 40% of patients will die within their first year of initiating hemodialysis. We investigate an expanded role for primary arteriovenous grafts (AVG) in this population.

Methods: We retrospectively review consecutive patients over the age of 70 who underwent upper extremity access creation from January 2008 to July 2014. Data collection included demographics, past medical histories, subsequent interventions, volume flows, access usage, and patient survival.

Results: We performed 366 AVF and 124 AVG creations in 442 patients over the age of 70 (197 women, 245 men). There were no significant differences in the comorbidities between the two access types. The AVG group was significantly older and more likely to be female, 79.2 yo vs. 77.2 yo ($p<0.001$) and 60% vs. 41% ($p<0.001$) respectively. Patients with AVF were significantly more likely to never use their permanent access, 25% vs. 11% (odds ratio: 2.6, $p=0.002$) and if utilized, cannulated significantly later, 3.6 ± 0.2 months vs. 1.3 ± 0.1 months ($p<0.001$). Catheter dependence at 6 months was 40% for AVF and 28% for AVG. (Figure 1) Secondary patency at 18 months was 64% for AVF and 63% for AVG.



Conclusions: Prosthetic grafts should be considered as the preferred permanent access type in the elderly. Better predictors of mortality, including frailty scores, should be investigated for determining the best choice of permanent access in elderly patients.

FR-PO699

Anticoagulation-Free Dialysis Is Not Associated with Failure to Meet Ultrafiltration Target: A Single-Center Inpatient Dialysis Study Rozina B. Ali, Akshatha Rao, Sandeep Aggarwal. *Div of Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia, PA.*

Background: Conventional outpatient hemodialysis utilizes various forms of anticoagulation to prevent access and extracorporeal circuit clotting. In contrast, to reduce the risk of bleeding events, inpatient dialysis units do not frequently use anticoagulation. We aimed to investigate the consequences of anticoagulation-free dialysis and the factors associated with failure to achieve ultrafiltration target (UFT) in our inpatient unit.

Methods: We performed a retrospective analysis of 250 consecutive hemodialysis treatments in 125 chronic patients. Patients were excluded if they were admitted for initiation of dialysis or required systemic anticoagulation. We looked at both instances of successful achievement and failure of UFT. We looked at the following factors: type of access, episode of intradialytic hypotension (IDH), episode of access clotting, and episode of extracorporeal circuit clotting. No anticoagulation was used in the HD treatments. Correlation analyses were performed and categorical data was analyzed using chi-square test. STATA, version 11, was used for statistical analyses.

Results: Overall the incidence of failure to meet UFT was 35%. Association of failure to meet UFT and episode of IDH was noted ($p=0.000$, Pearson $chi2(1) = 13.5$). There was no correlation between meeting UFT and type of access (graft $r=-0.09$, fistula $r=0.13$, and catheter $r=-0.07$), access clotting ($r=0.07$), and extracorporeal circuit clotting ($r=-0.08$).

Conclusions: Our study of 250 anticoagulation-free hemodialysis treatments suggests that access and extracorporeal circuit clotting was not associated with failure to meet ultrafiltration target. However, the failure to achieve ultrafiltration target was significantly associated with intradialytic hypotension. Larger cohort, multi-center prospective trials should be performed to look at causality of failure to meet ultrafiltration targets in the hospitalized patient.

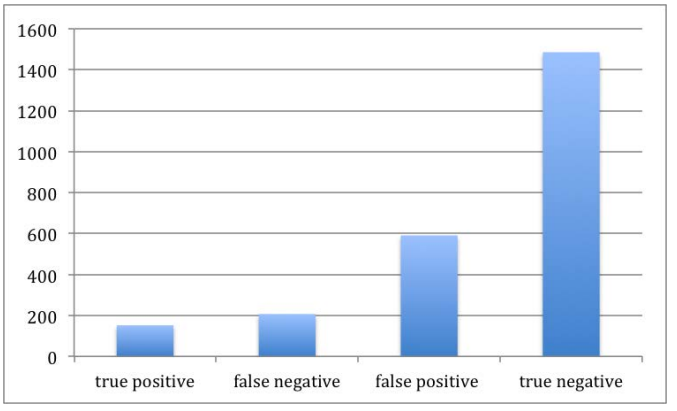
FR-PO700

Evaluation of the Ability of Transonic Monitoring to Predict Dialysis Access Stenoses Jerard Zaki Kneifati-Hayek,[1] Gaurav Ghosh,[2] Stephen Kruger,[3] Jeffrey I. Silberzweig.[1,2,3] *[1]Dept of Medicine, New York-Presbyterian Hospital, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]The Rogosin Inst, New York, NY.*

Background: Patency of vascular access is critical to successful maintenance hemodialysis. It is well established that lesions are easier to treat if they can be identified prior to thrombosis. Non-invasive evaluation of access blood flow with the Transonic device is established for this purpose. We previously analyzed its performance after two years and demonstrated >99% sensitivity and specificity[1]. We now seek to extend that work by looking at performance over a fifteen-year period.

Methods: Transonic studies are performed on approximately 1500 maintenance dialysis patients with AV grafts or fistulae in our 7 clinics in New York City. Transonic flow rates <600 cc/min or decreases by >10% from prior readings prompt referral to Interventional Radiology or Vascular Surgery. We report on the sensitivity, specificity and predictive values for patients treated between 1998 and 2012.

Results: Sensitivity was 42%; specificity 72%. Positive predictive value (PPV) was 20%; negative predictive value (NPV) was 88%.



We evaluated our ability to predict stenosis based on decreased dialysis clearance: for Kt/V, PPV was less than 10% and NPV less than 80% for different cutoff points; for URR, PPV was less than 10% and NPV less than 80%.

Conclusions: We hypothesize that the large numbers of false positive and false negative results were caused by scheduled referrals to Interventional Radiology, which have become routine. This study suggests that routine Transonic studies may no longer be as important as they were in 2000; however, Transonic studies provide better predictive ability than reductions in urea-based dialysis clearance.

FR-PO701

Hemodialysis Vessel Mapping in Women and Men Rita L. McGill, Robin Ruthazer, Dana Miskulin, Klemens B. Meyer, Daniel E. Weiner. *Tufts Medical Center, Boston, MA.*

Background: Men initiate hemodialysis (HD) with fistulas (AVF) more often than women, and this gap widens following initiation. Angiography and Doppler vessel mapping may promote AVF creation by detecting vessels not found by physical examination. Women may benefit more from imaging, as they are less likely to have veins that are visible upon inspection, even when suitable for AVF construction. We hypothesized that the sex disparity in AVF use may in part reflect a disparity in vessel mapping rates.

Methods: After restricting to patients with pre-dialysis Medicare claims, we used CPT codes to ascertain all vascular imaging during the 2 years before starting HD and up to 12/31/2012, in the subset of adult HD patients entering USRDS in 2010 or 2011 with central venous catheters (CVC) as sole vascular access. Doppler studies performed on the same day as an angiogram were excluded. Angiograms and Dopplers per 100,000 patients-months were calculated. Incidence rate ratios (IRR) between women and men were adjusted for age, race, BMI, diabetes, and vascular disease using Poisson regression.

Results: Among women with preHD claims, 62% had CVC-only and 14% AVF; men had 57% CVC-only and 20% AVF. 18494 men and 16686 women with CVC-only contributed 615257 and 558647 patient-months of data. No imaging was performed in 57% of men and 54% of women. The distribution of studies in men and women showed:

	MEN	WOMEN
N	18494	16686
ANGIOGRAPHY (# studies performed)	5705	5851
# individuals with Angiography	4058 (22%)	3986 (24%)
Crude IRR Angiography	---	1.13 [1.09, 1.17]
Adjusted IRR Angiography	---	1.11 [1.07, 1.15]
DOPPLER VEIN MAPPING (#studies performed)	5815	5746
# individuals with Doppler	4953 (27%)	4743 (28%)
Crude IRR Doppler	---	1.09 [1.05, 1.13]
Adjusted IRR Doppler	---	1.07 [1.03, 1.11]
# individuals with ANY imaging studies	8011 (43%)	7654 (46%)

Conclusions: Vascular imaging was performed in fewer than 50% of individuals starting hemodialysis with CVC. Higher rates of vascular imaging in women were statistically but not clinically significant. Promotion of vein mapping and angiography in women merits exploration as a means to decrease the disparity in fistula rates between women and men.

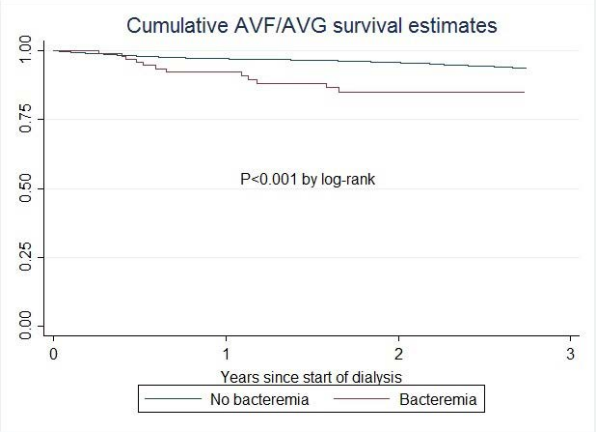
Association of Bacteremia with Arteriovenous Access Failure in Hemodialysis Patients Syed Mustafa Ahmed, Laura Plantinga, Rachel E. Patzer, Jason Cobb, William M. McClellan. *Emory Univ, Atlanta, GA.*

Background: Obesity, female sex, diabetes, peripheral vascular disease, and pacemakers are known risk factors for arteriovenous fistula (AVF) and arteriovenous graft (AVG) failure. We examined whether bacteremia in hemodialysis (HD) patients with AVF/AVG represents an additional, independent risk factor for subsequent AVF and AVG failure.

Methods: We conducted a retrospective observational study among 29,571 U.S. patients from the United States Renal Data System who started HD with AVF and AVG between 1/1/2009 and 9/30/2010. We used inpatient ICD-9 codes after dialysis start to define bacteremia and AVF/AVG failure. We then used a multivariable Cox proportional hazards model to assess relationship between exposure to bacteremia and time to access failure.

Results: Overall, 12.2% of patients with bacteremia experienced an access failure, compared to 4.0% of patients without bacteremia (P<0.001). This difference persisted over a median follow-up of 582 days. With adjustment for known confounders, patients who had bacteremia after dialysis start were at >3-fold greater risk of subsequent access failure, relative to those who did not (HR=3.18, 95% CI: 1.71– 5.95).



Conclusions: This observational study indicates that decreased AVF and AVG survival may be associated with exposure to bacteremia among HD patients.

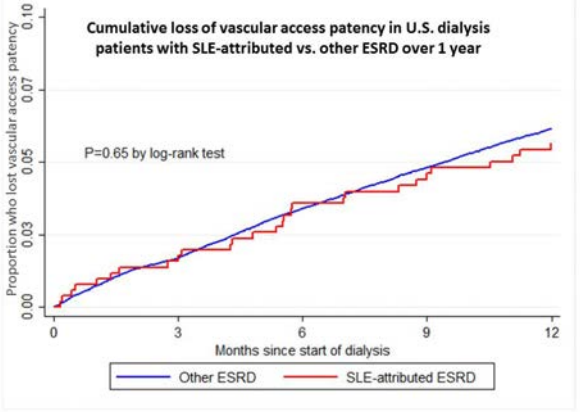
FR-PO703

Comparison of Loss of Vascular Access Patency in Hemodialysis Patients with End-Stage Renal Disease due to Systemic Lupus Erythematosus versus Other Causes Laura Plantinga, Sung S. Lim, Rachel E. Patzer, Stephen O. Pastan, Cristina Drenkard. *Emory Univ, Atlanta, GA.*

Background: Previously we found that U.S. patients with systemic lupus erythematosus (SLE) and end-stage renal disease (ESRD) were 40% less likely than other ESRD patients to have a permanent vascular access in place at the start of dialysis. Here, we examine whether subsequent loss of patency differs in SLE vs. other ESRD patients who have a permanent vascular access.

Methods: A cohort of 106,993 U.S. patients starting hemodialysis with an arteriovenous fistula or graft (7/05-9/11) was identified from a national registry of treated ESRD (United States Renal Data System). Kaplan-Meier analyses and multivariable Cox proportional hazards models were used to estimate the association between SLE vs. other ESRD (by provider-reported attributed cause at start of dialysis) and the time to first inpatient ICD-9 code for loss of vascular access patency, with censoring for death or the end of follow-up.

Results: A total of 597 (0.6%) incident hemodialysis patients with a permanent vascular access had ESRD attributed to SLE. Over a median total follow-up of 1.9 years (IQR, 0.9-3.3 years), SLE vs. other ESRD patients had similar likelihood of loss of patency [HR=0.87 (95% CI, 0.70-1.09)].



Results were similar within the first year of dialysis [HR=0.91, 95% CI, 0.62-1.33] and, with adjustment for demographics and clinical variables, the association remained null [HR=1.13 (95% CI, 0.80-1.65)].

Conclusions: These results suggest that, among those patients who do start dialysis with a permanent vascular access, those with SLE are not more likely than other patients to experience a loss of vascular access patency requiring hospitalization. Further analyses will examine whether these patterns persist when outpatient procedures are included; however, confounding by indication would remain a potential bias.

FR-PO704

The Placement of Tunneled Central Venous Catheters Through Percutaneous Puncture of Superior Vena Cava in Hemodialysis Patients Tianlei Cui, Xiaoxi Zeng, Yanhuan Feng, Ping Fu. *Nephrology Dept, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.*

Background: After the exhaustion of traditional insertion sites of tunneled central venous catheters (tCVCs), it can be challenging to place the tCVCs in exotic locations. A retrospective case series in West China Hospital was studied to assess the placement of tCVCs through percutaneous puncture of superior vena cava (SVC) in patients with innominate veins occlusion.

Methods: Sixteen patients (male: 62.5%; mean age: 64.7 years; mean duration of HD: 5 years) who underwent placement of tCVCs through percutaneous puncture of SVC were retrospectively analyzed. They had either exhausted AV access sites or chosen not to undergo other vascular access placement. All of the patients had occlusion in innominate veins on both sides. The outcomes were function measurements of tCVCs, and safety parameters. The technique: With patients supine, following the guidance of fluoroscopy, a 5-F catheter was placed at the distal end of SVC through the femoral vein, iliac vein or hepatic vein, serving as a fluoroscopic target. Later, guided by fluoroscopy vertically and horizontally, the puncture needle and sheath were placed into SVC through a percutaneous route with the insertion site at 0.5-1.0 cm lateral-inferior to the clavicle head of sternocleidomastoid, allowing the access of the guidewire and the placement of a tCVC.

Results: The procedure succeeded in all of the patients. During the follow-up (mean: 12 months, range: 3-36 months), access failure due to thrombosis was observed in one patients, and the failure was treated by aspirin and Clopidogrel. The remaining continued to function well until the end of the follow-up or until the death of the patients (n=3). The procedure was generally safe. No pneumothorax occurred. The most common complication was mediastinal hematoma after the failure of SVC puncture. The fluoroscopy could reveal the hematoma during the procedure. The largest hematoma was 2cm in diameter in the current series and it resolved spontaneously.

Conclusions: In patients with innominate veins occlusion and exhaustion of the conventional insertion sites, the tCVCs can be safely placed through SVC puncture using percutaneous route.

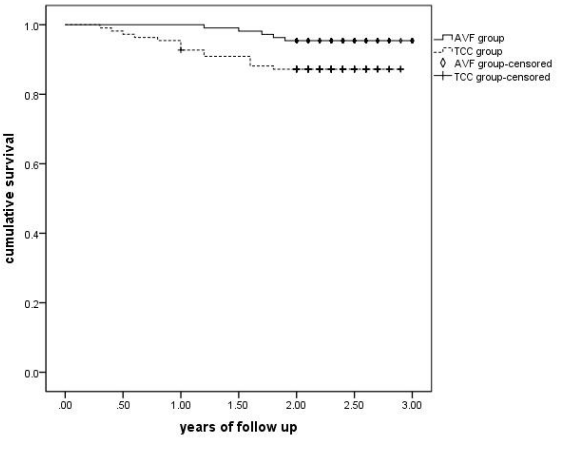
FR-PO705

Analysis of Survival of Cardiac Function in Maintained Hemodialysis Patients with Arteriovenous Fistula and Tunneled Cuffed Catheter Li Hua Wang, Fang Wei, Ai Li Jiang. *Dept of Kidney Disease and Blood Purification Centre, Inst of Urology & Key Laboratory of Tianjin, 2nd Hospital of Tianjin Medical Univ, Tianjin, China.*

Background: Untill now ,there is little data of cardiofucntion regarding to different type of vascular access.This study was to investigate survival of patients with arteriovenous fistula and tunneled catheter on maintained hemodialysis in terms of cardiacfunction.

Methods: A total of 219 patients who received maintained hemodialysis were included in this study. Patients were divided into two groups: arteriovenous fistula group and tunneled catheter group.The baseline anthropometric and 1aboratory parameters were measured. The time and cause of mortality were documented.

Results: There were significant difference of left ventricular hypertrophy[x^2=6.645, P=0.001], left ventricular stystolic dysfunction[>x^2=4.007, P=0.045], between two groups. But there was no significant difference of left ventricular diastolic dysfunction between two groups.Kaplan-Meier survival curves showed that the mortality was enhanced among tunneled catheter group.



Patients with left ventricular hypertrophy ,left ventricular stystolic dysfunction, left ventricular diastolic dysfunction in arteriovenous fistula group have a high survival rate compared wtih tunneled catheter group. Furthermore iPTH, calcium, stystolic blood pressrue and diastolic blood pressure were the independent risk factors of mortality for patients on maintained hemodialysis by COX regression model.

Conclusions: Different type of vascular access may have influence on mortality in patients on maintained hemodialysis. Those with tunneled catheters have lower survival rate when left ventricular dysfunction occurred.

FR-PO706

A Retrospective Study of Preferable Alternative Sites to Right Internal Jugular Vein for Tunneled Hemodialysis Catheters Insertion: Right External Jugular Vein versus Left Internal Jugular Vein Yufei Wang, Pei Wang, Xianhui Liang, Xiaoqing Lu, Zhangsuo Liu, Yingjin Qiao, Sijie Zhou. *Blood Purification Center, The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.*

Background: It has been recommended by the KDOQI guidelines that right internal jugular vein (RIJV) is a preferred insertion site for hemodialysis (HD) catheters, and both right external jugular vein (REJV) and left internal jugular vein (LIJV) are alternative sites for those who have encountered severe thrombosis and/or occlusion of RIJV. The retrospective study aimed to determine if superiority exists in the two alternative sites by comparing the outcomes of tunneled (cuffed) dialysis catheters (TDCs) through REJVs versus LIJVs in HD patients who had failed RIJV.

Methods: From January 1, 2013 to December 31, 2014, 28 LIJV-TDCs and 21 REJV-TDCs were inserted in our hospital. All events were recorded from patient charts until May 31,2015. Using SPSS 22.0 software, data were analyzed by the Fisher exact test or chi-square test. Event free catheter survival was estimated by the Kaplan-Meier method. Multivariable Cox hazards analysis was fitted to detect the independent risk factors of events. A p-value of <0.05 was considered statistically significant.

Results: A total of 20924 (LIJVs, 11782; REJVs, 9141) catheter-days were evaluated and the mean was 427.02 days. Most of the patients (53.1%) were older than 65 years with an average dialysis time of 25.3 months. The event free catheter survival time was (516.20±55.60)d in REJV-TDCs and (343.91±40.63)d in LIJV-TDCs (P=0.038). Mean effective blood flow was higher in REJV-TDCs than that in LIJV-TDCs (270.95±24.93 vs 244.82±30.35ml/min, P=0.02). A substantial trend toward statistical significance was found between two groups in incidence of all events, including death, death related to catheter complication and catheter removal. The total historic catheters indwelling time was identified as an independent risk factor for severe TDCs events by Cox regression hazards test (p= 0.01).

Conclusions: REJV might be superior to LIJV as an alternative insertion site for TDC placement in in HD patients who had failed RIJV.

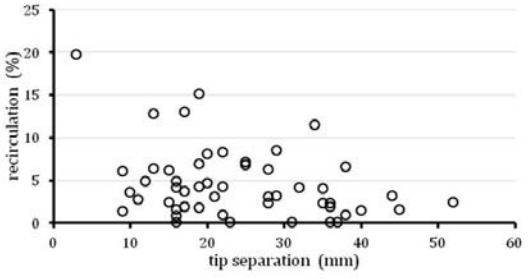
FR-PO707

Haemodialysis Recirculation in Patients with Catheter Access Damien Ashby. *Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom.*

Background: Recirculation is a well described impairment of the haemodialysis circuit which reduces dialysis dose and electrolyte clearance. Catheter tips are designed to minimise recirculation based on in vitro experiment, with most designs having a tip separation of 25mm, but clinical studies of catheter-related recirculation have not been published.

Methods: In a group of stable adult patients receiving haemodialysis by tunnelled catheters, recirculation was calculated by 3-sample urea measurement, and analysed in relation to line tip separation (measured by chest X-ray) and routinely collected clinical parameters. All patients were using paired Tesio catheters.

Results: In 54 haemodialysis patients (aged 28-90, 61% male) median recirculation was 3.7% with IQR 1.9-6.3%, range 0-19.7%, and a heavily left-skewed distribution (modal range 0-2%). Greater than 5% recirculation was seen in 30% of patients. Tip separation (range 3-52mm) was strongly associated with recirculation (R=-0.33, p=0.014), which also appeared to have a weak association with body weight (R=0.21, p=0.13).



Defining thresholds to avoid high recirculation (>5%): with tip separation over 25mm high recirculation was seen in 6 patients. Increasing threshold tip separation to 30mm reduced the number of patients with high recirculation to 2. The same was achieved using a weight-based tip separation threshold of 0.5mm/kg. High recirculation was associated with high erythropoietin requirement (R=0.29, p=0.030) but not with low Kt/V (p=0.26).

Conclusions: Significant recirculation affects a significant minority of patients dialysing on tunnelled catheters, and is closely related to tip separation. A tip separation threshold of 25mm may be inadequate to avoid high recirculation, and 30mm or perhaps a weight-based threshold may be superior. Erythropoietin resistance is a possible consequence of this type of haemodialysis recirculation.

Risk Factors for Fatal Dialysis Access Haemorrhage Nicole M. Lioufas,[1] Jonathan E.H. Ling,[1] Gail Theresa Read,[1] Matthew D. Jose.[1,2] *[1]Royal Hobart Hospital, Hobart, Tasmania, Australia; [2]School of Medicine, The Univ of Tasmania, Australia.*

Background: Haemodialysis requires access to the circulation via an arteriovenous fistula or graft, or a synthetic vascular catheter. Annually there are deaths associated with catastrophic bleeding from dialysis vascular access.

Methods: A systematic search strategy including data from the National Coronial Information System (NCIS, containing coroner's reports from all Australian states and New Zealand), the Australian and New Zealand Dialysis and Transplant registry (ANZDATA), published cases from Australia and New Zealand, individual renal units and State Renal Network reports. Data was analysed for all deaths where cause of death was reported as being due to dialysis access haemorrhage from 1st January 2000.

Results: A total of 83 patients (mean age 67 years (range 30 – 89), 55% female) receiving renal replacement therapy died due to dialysis vascular access haemorrhage. These were identified through NCIS 54, ANZDATA 64, State networks 3, Publications 2 and individual renal units 2. Most deaths were attributable to problems with vascular access including infection (22%), dialysis catheter problems (17%), recent access intervention (15%) or use of a thigh arteriovenous fistula (11%). Bleeds commonly occurred at home in people treated with satellite haemodialysis. Modality at the time of death was home haemodialysis in 12 people. Use of Warfarin or cognitive impairment was identified in only 1 death each. Coronial inquests and Root Cause Analyses were identified in only 7 deaths with recommendations involving communication, staffing, clinical policy, practice changes and equipment modification.

Conclusions: Death due to dialysis access haemorrhage is an uncommon, catastrophic, but potentially preventable event. A number are preceded by vascular access infection, vascular access complications or recent intervention. Only a minority of deaths have been investigated, but where they have, critical recommendations for optimising future care are presented.

FR-PO709

Subcutaneous Implantable Electronic Devices in Chronic Kidney Disease and Hemodialysis Patients Rizwan K. Alimohammad, Rahim Dhanani, James O'Brien, Syed S. Haqqie, Arif Asif. *Albany Medical College.*

Background: While epicardial leads have been reported to bypass central venous stenosis, their placement is much more invasive and requires the services of a cardiothoracic surgeon. Recent data have demonstrated successful defibrillation using a subcutaneous ICD (SICD). While the use of these devices is expanding, their insertion in advanced renal failure and hemodialysis patients is somewhat limited. In this analysis, we present 9 CKD and 4 hemodialysis patients treated successfully with an SICD. Demographic characteristics revealed; male=8, diabetes=8, hypertension=13, coronary artery disease=10, peripheral vascular disease=8. Two of the four hemodialysis patients had an AVF while two were dialyzing with a tunneled dialysis catheter. Mean GFR for the CKD patients was 40±3 ml/min. Patients received the SICD device for primary prevention of sudden cardiac death (cardiomyopathy with low ejections fraction). 3/13 patients had non-ischemic cardiomyopathy (CMP) with an ejection fraction of <25% while 10/13 suffered from ischemic CMP with an EF of <30%. There were no procedure-related complications in terms of excessive bleeding, hematoma or infection. At an average follow-up of 6 months, one death has occurred that was unrelated to the procedure or arrhythmia. Subcutaneous ICD is a minimally invasive procedure when compared with an epicardial device. By leaving the venous system untouched, this approach offers the advantage of reduced risk of central venous stenosis and infection over an endocardial ICD with transvenous leads. This approach is particularly helpful for CKD and hemodialysis patients who rely on venous capital for their survival. SICD has been FDA approved and is currently being utilized in the United States and Europe.

Methods: Restrospective evaluation of SICD in patients with CKD and ESRD.

Results: Thirteen patients with CKD and ESRD on dialysis received successful SICD.

Conclusions: SICD can be successfully used in patients on hemodialysis and CKD.

FR-PO710

Modified Non-Transposed Brachiobasilic Arteriovenous Fistula for Hemodialysis: A Randomized Controlled Study Dayong Hu,[1] Chunyu Zhou,[1] Chandra Mohan,[2] Changbin Li,[1] Jie Tang,[3] Ai Peng.[1] *[1]Shanghai Tenth People's Hospital, Tongji Univ School of Medicine, Shanghai, China; [2]Univ of Houston, Houston, TX; [3]DHHA-Univ of Colorado School of Medicine, Aurora, CO.*

Background: Transposed brachiobasilic arteriovenous fistula (BBAVF) is technically challenging. It not only associates with severe arm swelling and pain, but also takes longer to be ready for use. Here we introduce a novel modified non-transposed BBAVF (mNT-BBAVF), and compare its outcomes to those of the standard brachiocephalic arteriovenous fistula (BCAVF).

Methods: From January 2010 to December 2012, 74 incident hemodialysis patients with suitable basilic and cephalic veins were randomized equally into mNT-BBAVF and

BCAVF groups. All participants were followed for 12-months after surgery. The main outcomes were blood flow velocities and volumes, vessel diameters, primary unassisted fistula patency rate (PUFPR), the cumulative fistula survival rate (CFSR) and complications.

Results: The baseline demographic and clinical characteristics were well matched between mNT-BBAVF and BCAVF groups. Blood flow velocities and flow volumes of the corresponding fistula segments increased significantly in both groups. Compared to BCAVF where only proximal cephalic vein increased in size, the proximal cephalic vein, distal cephalic vein and distal basilic vein in mNT-BBAVF all increased significantly compared to baseline over the 12-month period ($p<0.01$). Therefore, in addition to the proximal cephalic vein, the distal cephalic vein and distal basilic vein were also available for cannulation in mNT-BBAVF. At 12 months, the PUFPR of mNT-BBAVF was significantly better than that of BCAVF (73.0% vs. 45.9%, HR: 2.60; 95%CI: 1.21 to 5.59; $p=0.01$). Although, the CFSR did not differ between the two groups (91.9% vs. 78.4%, HR: 1.68; 95%CI: 0.55 to 5.17; $p=0.37$). Finally, there were no significant differences in complications between the two intervention groups at 1 and 12 month follow-ups, other than severe arm pain which was much less reported among patients with mNT-BBAVF at 1 month (vs. BCAVF, $p=0.03$).

Conclusions: mNT-BBAVF is an effective alternative for the construction of upper arm vascular access.

FR-PO711

Management of Catheter Related Bacteraemias: New Insights into an Old Problem Benjamin A. Oliveira,[1] Conor James Byrne.[1] *[1]Renal Medicine, Royal London Hospital, London, United Kingdom; [2]Renal Medicine, Royal London Hospital, London, United Kingdom.*

Background: Catheter related bacteraemias (CRB) pose a significant risk for those dialysing via such devices. Strategies are needed to minimise this risk as much as possible, especially in light of growing concerns over antibiotic resistance. Our unit routinely uses citrate to lock catheters. We sought to audit our CRB rate and long term complication rate. We believe this contemporary data will be useful to all involved in caring for patients with catheters.

Methods: We retrospectively reviewed all blood cultures taken from our institution's dialysis patients for 1 year (October 2013 and September 2014). The records of patients with positive cultures were reviewed to ascertain if the infection was related to their access. Data was then collected on the type of organism grown, management of the episode, recurrence rate, and any long term complications.

Results: 1014 cultures were taken from approximately 930 haemodialysis patients. 45% of these were dialyzing via a catheter. There were 52 instances of CRB giving a CRB rate of 0.34 per 1000 catheter days. 65% were due to gram-positive organisms, 29% were due to gram-negative organisms and 6% were fungal related. The overall recurrence rate was 26%. Catheter removal was performed in 32 instances (62%). Infective complications occurred in 5 (16%) patients with gram-positive infections and 6 (54%) of those with gram-negative infections; a statistically significant difference. The majority of these were endocarditis. CRB accounted for a total of 583 hospital in-patient days.

Conclusions: We observed significantly more infective complications with gram-negative organisms compared with gram-positive. This probably reflects the underlying characteristics of these patients rather than the pathogenicity of the organisms per se (19% of patients with gram-negative infections were intravenous drug users). Never the less our data suggests that gram negative infections are a risk factor for complications and clinicians should consider further investigations in these cases. Our CRB rate was low compared to quoted rates in the literature; this may reflect routine the use of citrate lock in our catheters.

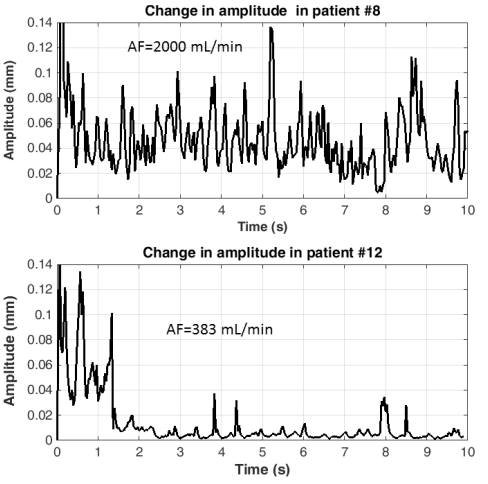
FR-PO712

Assessment of Arteriovenous Fistula Access Flow Using Video Image Processing Technology Schantel Williams,[1] Hannah Putnam,[1] Viviane Calice-Silva,[1,2] Israel David Campos Gonzalez,[1] Peter Kotanko,[1,3] Fansan Zhu.[1] *[1]Renal Research Inst, NY, NY; [2]Pontificia Univ Católica do Paraná, Curitiba, Brazil; [3]Icahn School of Medicine at Mount Sinai, NY, NY.*

Background: Vascular stenotic lesions are the main cause of failure in arteriovenous fistulas (AVF). Routine measurement of access flow (AF) is important in the timely detection of changes and planning interventions. The aim of this pilot study was to investigate whether video image processing (VIP) techniques can be used to detect AVF motion and explore the relationship between motion patterns and AF.

Methods: Skin above the AVF was imaged for 1 minute using a digital single lens reflex camera prior to HD. The video was processed using Eulerian video magnification (Wu et al*ACM Trans.Graph.*31(4), 2012) to amplify AVF motions. Thereafter the motion-amplified video was converted to quantitative waveform data using an algorithm based on change in color of each image (Matlab Image Processing Toolbox). Monthly AF measurements were recorded and correlated with the post-processed AVF waveform pattern.

Results: We studied 12 hemodialysis patients (51.5±11.3 years, 50% male) with a mean±SD AF 1501±392ml/min (N=9; AF was unavailable in 1 subject). Amplitude of skin displacement was 0.069±0.04mm (N=9; technical issues occurred in 2 subjects). While amplitudes of that size are hardly visible to the naked eye, they were clearly discernible in post-processed amplified videos. Amplitude was notably smaller in subjects with lower AF (Fig. 1). Amplitude analysis of the amplified video indicates a relationship with AF ($R^2=0.73$, $p<0.01$; N=9).



Conclusions: Our proof-of-concept study demonstrates this video imaging and analysis technique has potential to provide a quick, noninvasive, low cost way to obtain quantitative information related to AF. Research is underway to assess the impact of clinical interventions of the amplitude pattern.

Pre-Emptive Correction of Arteriovenous Access Stenosis: Systematic Review and Meta-analysis of Randomized Controlled Trials Pietro Ravani,[1] Robert R. Quinn,[1] Matthew J. Oliver,[2] Divya J. Karsanji,[1] Matthew T. James,[1] Jennifer M. MacRae,[1] Suetonia Palmer,[3] Giovanni F.M. Strippoli.[4] *[1]U of Calgary, Canada; [2]U of Toronto, Canada; [3]U of Otago, New Zealand; [4]Diaverum, Italy.*

Background: Elective stenosis correction in an arteriovenous (AV) access that is suitable for hemodialysis may prolong its survival, as compared to salvage procedures postponed to when the AV access becomes dysfunctional.

Methods: We did a systematic review and meta-analysis of randomized controlled trials (RCTs) evaluating pre-emptive correction of an AV access stenosis vs. stenosis correction in a dysfunctional access (deferred correction) in adults treated with hemodialysis therapy. We searched the Cochrane Kidney and Transplant Specialized Register (which includes MEDLINE and EMBASE) to 29 October 2014. Outcomes of interest were access loss (primary outcome), access thrombosis, infection, mortality, hospitalization, and access-related procedures. We did sub-group analyses of access outcomes by access type. We summarized the evidence using the Grading of Recommendations Assessment, Development, and Evaluation criteria.

Results: We included 14 studies (involving 1,390 participants; follow-up 6-38 months; N=58-189 participants). Nine studies enrolled adults without access stenosis (primary prophylaxis; three studies including people using fistulas) and five enrolled adults with a highly suspected or documented stenosis in a functioning access (secondary prophylaxis; three studies in people using fistulas). Relative to deferred salvage, access surveillance with pre-emptive correction of an AV stenosis did not reduce the risk of thrombosis (RR 0.95; 95% CI 0.8-1.12) or access loss (RR 0.9; 95% CI 0.71-1.15) in grafts (moderate-grade evidence), but reduced the risk of thrombosis (RR 0.5; 95% CI 0.35-0.71) and access loss (RR 0.5; 95% CI 0.29 to 0.86) in fistulas (low-grade evidence). Results were either heterogeneous or imprecise for mortality, rates of infection, procedures and hospitalization. There was unclear or high risk of bias in most studies.

Conclusions: Pre-emptive correction of a new or documented stenosis may not improve graft outcomes, but may prevent fistula thrombosis or loss.

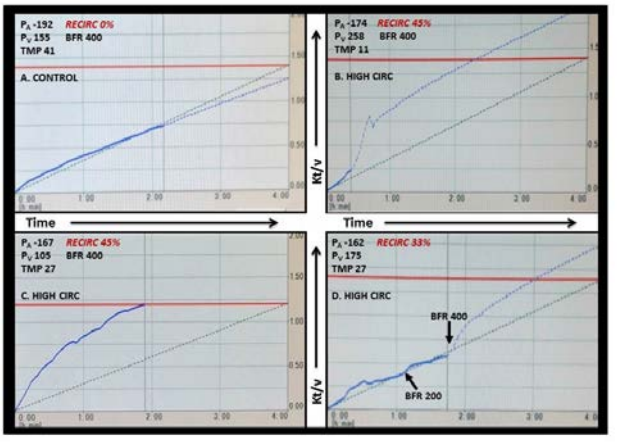
FR-PO714

Real-Time Kt/V Tracking Profile as a Predictor of Dialysis Access Recirculation Abhilash Koratala, Girish Singhania, A. Ahsan Ejaz. *Nephrology, Univ of Florida, Gainesville, FL.*

Background: On-line monitoring of ultraviolet absorption of spent dialysate in routine hemodialysis allows continuous measure of removed solutes from spent dialysate. We studied whether real-time Kt/V tracking profile could be a predictor of dialysis access recirculation.

Methods: End-stage renal disease patients undergoing maintenance dialysis with Dialog (B Braun AG) dialysis machine with a built-in UV-Spectrophotometer (Option Adimea, B Braun AG), high-flux polysulfone dialyzers, and at blood flow rate (Q_b) 400-450mL/min and dialysate flow rate (Q_d) 800ml/min were included in all recording sessions. Real-time Kt/V tracking profile and venous (P_V) and arterial pressures (P_A) were recorded and hemodialysis access recirculation values were biochemically measured using standard protocol.

Results: Distinct real-time Kt/V profiles were identified in patients with significant access recirculation (>5%) vs. none (Control).



In the control profile, real-time Kt/V (Fig 1a, solid line) closely followed the target line (Fig 1a, dashed line) and was associated with normal P_A and P_V. In patients with high access recirculation, real-time Kt/V tracking line deviated widely from the target line (High Recirc Kt/V Profile; Fig 1b, c, d) and remained deviant throughout the treatment session. Fig 1d. demonstrates a case wherein the initial low Q_b provided false impression of normal access function, however increasing Qb resulted in unmasking of high access recirculation, i.e., appearance of High Recirc Kt/V Profile. High access recirculation was confirmed by biochemical methods. Interestingly, all High Recirc Kt/V Profile events were associated with abnormal recirculation values, but not all were associated with elevated P_V.

Conclusions: Real-time Kt/V tracking profile provides a non-invasive, inexpensive and quick assessment of access recirculation in hemodialysis patients.

FR-PO715

Recurrent Vascular Access Stenosis as a Novel Marker for Cardiovascular Outcome in Hemodialysis Patients Hyo Jin Kim, Hajeong Lee, Dong Ki Kim, Kook-Hwan Oh, Yon Su Kim, Curie Ahn, Kwon Wook Joo. *Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

Background: Vascular access (VA) is essential component and its stenosis is a major complication in hemodialysis (HD) patients. Nevertheless, there are few data for outcomes of patients who had recurrent VA stenosis. We have explored the influence of recurrent VA stenosis on cardiovascular (CV) event, patient death, and VA failure.

Methods: This is a single-center, retrospective study. Patients who had VA operation at Seoul National University Hospital between January 2009 and March 2014 were enrolled. Patients who had two or more instances of percutaneous angioplasty or revision operation within 180 days were categorized recurrent group. The primary outcome was CV events, as coronary artery or heart failure or cerebrovascular, and or peripheral vascular events. The secondary outcomes were all-cause mortality (ACM), composite of ACM or CV events, and VA failure. The two groups were compared before and after matching with propensity scores (PSM).

Results: A total of 766 patients (59.7% male, age 59.6 ± 14.3 years) were analyzed. Recurrent group patients (n = 77; 10.1%) were older and had higher underlying CV disease and dyslipidemia. A total 213 patients (142 in non-recurrent, 71 in recurrent group) were selected by PSM. During 28.7±15.8 months follow-up, 46 patients (21.6%) had CV outcomes, 30 patients (14.1%) died, and 14 patients (6.6%) experienced vascular access failure. After adjustment, recurrent group was an independent risk factor for CV events (adjusted hazard ratio [HR] 2.66; 95% confidence interval [CI] 1.46–4.86, $P = 0.001$) and composite of ACM or CV events (adjusted HR 1.99; 95% CI 1.21–3.27, $P = 0.007$). However, it was not associated with increased ACM and VA failure.

Conclusions: Recurrent VA stenosis was a novel independent risk factor for CV event in HD patients, rather than VA failure. For patients suffered from recurrent vascular stenosis, diligent monitoring should be warranted not only for VA patency but also for CV events.

FR-PO716

Stent Insertion Is an Important Tool in Maintaining Arteriovenous Access Patency Stephen G. John,[1] Kumar Abayasekara,[2] Peter M. Bungay,[3] Mario De Nunzio,[3] James E. Kirk,[3] John Graham Pollock,[3] Peter D. Thurley,[3] Paul J. Owen,[1] Richard J. Fluck,[1] Lindsay J. Chesterton.[1] *[1]Nephrology, Royal Derby Hospital; [2]Vascular Surgery, Royal Derby Hospital; [3]Radiology, Royal Derby Hospital, Derby, United Kingdom.*

Background: Definitive access for haemodialysis (HD) remains the cornerstone of optimal dialysis. However, HD patients are becoming older, access attempts more problematic and vein preservation remains critical. Clinical examination and access monitoring enable appropriate, timely, endovascular intervention. Stents may be inserted for recurrent stenosis or after endovascular rupture, but their role remains debatable. We report on our single-centre experience of access surveillance and endovascular intervention, highlighting the role of stent insertion.

Methods: Electronic hospital records were retrospectively analysed in all access-related stents inserted from 2006-2014 by 5 vascular radiologists.

Results: 49 stents were inserted during 45 procedures in 39 patients. 12 had diabetes. Mean age was 64.5±25.5 yrs, median dialysis vintage was 1162±1504 days (range 5-5027). Median time from access creation (82% arteriovenous fistula) to stent insertion was 318±926 days (range 31-3752). 34 stents were inserted peripherally (cephalic arch and distally), the majority in the cephalic arch. Equal numbers of covered and bare-metal stents were inserted. 4 stents were placed in thrombosed access. 7 procedures were due to surveillance alone, a further 8 due to surveillance and pressure/flow problems. 12 stents were inserted for rupture or dissection (overall access procedure complication rate 1%). Median time from first stent to access failure/ceased HD was 333±653 days, assisted by median 2 (range 0-11) further procedures. Treatment for rupture was not associated with significantly shorter access longevity. Only 10 patients' access failed during follow-up. Our overall HD definitive access prevalence rate was 86-90%.

Conclusions: Appropriate HD access is essential in minimising HD morbidity. We reserve stent insertion for rapidly-recurring stenosis or rupture during endovascular procedures. Our data suggest that appropriate, judicious stent insertion in an appropriately structured pathway results in access durability and longevity.

FR-PO717

Association of Vascular Access Flow and Volume Status on Fistula Arm by Bio-Impedance Analysis in Hemodialysis Patients Hun Jeong,[2] Hyung Jong Kim,[1] Eun jung Ko,[1] Younhee Lee.[1] *[1]Internal Medicine, CHA Bundang Medical Center, CHA Univ, Seongnam, Korea; [2]Internal Medicine, Seoul Bukbu Hospital, Seoul, Korea.*

Background: Multi-frequency bioimpedance is a tool of body composition measure and can monitor changes in extracelluar volume during dialysis. Arterio-venous fistulae(AVF) could potentially affect fluid retention in the arm. We investigated whether multi-frequency bioimpedance could detect AVF stenosis or association of AVF with fluid retention in the AVF arm.

Methods: We measured the extracellular water(ECW) and total body water(TBW) in AVF arm following hemodialysis by multi-frequency bioimpedance(Inbody S10®) using an eight-electrode contact technique. We measured AVF flow by transonic ultrasonography using an ultrasound dilution technology (HD 03®) in hemodialysis.

Results: Total 28 patients (male 13 patients) were enrolled and the mean age of patients was 54.89 ± 13.21 years. ECW/TBW ratio of fistula arm was a significantly higher than ECW/TBW ratio of non-fistula arm(0.389 ± 0.01 vs 0.382 ± 0.001; p<0.05). ECW/TBW ratio of fistula arm was a significantly negative correlation with access flow level (mL/min) on fistula(p< 0.05). The 5kHz reactance of fistula arm was a significantly positive correlation with access flow level (mL/min) on fistula(p<0.05).

Conclusions: Absolute and also relative extracellular fluid volumes are increased in the fistula arm of hemdialysis. We thought that extracellular fluid volumes in the fistula arm were associated with access flow level (mL/min) and/or relative fistula stenosis. We suggest that multi-frequency bioimpedance can be a useful assistant tool of vascular access flow measure.

FR-PO718

Does Pre- and Post-Angioplasty Doppler Ultrasound Evaluation Help Predicting Vascular Access Outcome? Maria Guedes Marques, Pedro Maia, Fernando Neves, Aníbal Ferreira, Carlos Oliveira, Carlos Barreto, João Cruz, Dulce Carvalho, Telmo Carvalho, Pedro M. Ponce. *Vascular Access Center - Nephrocare Lumiar, Portugal.*

Background: KDIGO Guidelines recommend post-angioplasty (PTA) lesion should have <30% residual stenosis (RS) and hemodynamic parameters should improve. Access blood flow (ABF) is one of the most used. Primary end point: how post-PTA ABF improvement could predict vascular access (VA) outcome. Secondary: compare doppler ultrasound (DU) and angiography diagnostic accuracy; determine how other factors could predict outcome.

Methods: Prospective study in 80 patients with dysfunctional VA. DU evaluation was performed pre and post-PTA. Several parameters were recorded. Secondary patency verified during first 6 months.

Results: Initial DU in 80 patients; 26 excluded due to abnormalities absence or impossible endovascular approach - final 54. Two thirds male; age 68±15y; VA time 36±29months; initial ABF 537±248ml/min; final ABF 1013±354ml/min. Number and location of stenosis was highly correlated between DU and angiography (Pearson 0,828; p 0.000); mismatching in central vessels. Overall survival 83% at first trimester and 63% at semester; significantly better for fistulas (76%) than grafts (51.7%), p 0.044. Final angiographic RS>30% occurred in 14.8% patients, who had significantly better survival, p 0.038. Initial ABF<500 ml/min and multiple stenosis didn't affect the outcome (p 0.189 and p 0.811). A >2-fold ABF increase had no significant impact on fistulas survival (p 0.339) but it was highly significantly associated with worst outcomes in grafts (23.1% vs 73.5%, p 0.009). VA failure HR was 3.3 for grafts (p 0.034).

Conclusions: DU diagnostic accuracy is highly correlated with angiography. Although less accurate for central lesions, has a key role due to morphologic and hemodynamic assessment. PTA is a powerful therapy with immediate benefit; however final angiographic RS is not predictive of outcome. Grafts have worst patency, demanding more interventions. PTA is associated with mechanical endothelial injury. Higher ABF induce more turbulent flow that is likely to cause more intimal hyperplasia, which could explain the shorter patency, especially in grafts where inflammation is higher.

FR-PO719

Why Are Catheters Still Used to Initiate Hemodialysis Treatment of ESRD? Tanya Tocharoen Tang, Shubhada N. Ahya, James J. Paparello, Murray L. Levin. *Dept of Medicine/Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.*

Background: Complications of long-term use of tunneled catheters for hemodialysis involve a high risk of infection, thrombosis, hospitalization and expense. This study reviews a single center experience to identify factors that may contribute to the high rate of patients initiated with tunneled HD catheters.

Methods: We conducted a 13-question survey of 47 CKD patients who had been newly initiated on dialysis through a tunneled central vein dialysis catheter during their hospital admission in a university hospital from December 2013-May 2015.

Results: Of 47 subjects, 27 were male and 20 female. Subjects' mean age was 60 years old. Demographics included 26/47 (55%) African Americans, 7/47 (15%) Hispanics, 12/47 (26%) Caucasians and 2/47 (4%) Asian. Ninety-six % of patients (45/47) had been seen by a physician within the past year, and had been told their kidney function was poor. Eighty-three % of patients (39/47) were referred to a nephrologist. Thirty-six patients saw a nephrologist and, of those patients, only 13 patients were referred to a surgeon for access. Of the patients who saw a nephrologist, twenty two % (6/36) did not follow through with access placement secondary to noncompliance. Thus, of 47 patients starting hemodialysis with a catheter, only 7 had actually seen a surgeon for access placement. The largest drop off in the continuum of care of the patient is between seeing the nephrologist and seeing the surgeon. Since half of the patients surveyed received care elsewhere, it indicates this finding is not unique to our institution.

Conclusions: There are numerous points in the path to arteriovenous access where attrition occurs. Nephrologists and primary care physicians must oversee proper follow up and follow through to assure successful access placement. In our study, we found that there is a big attrition point from nephrology to surgery referral. A coordinator to help follow up patients or a joint clinic are options to improve this problematic step.

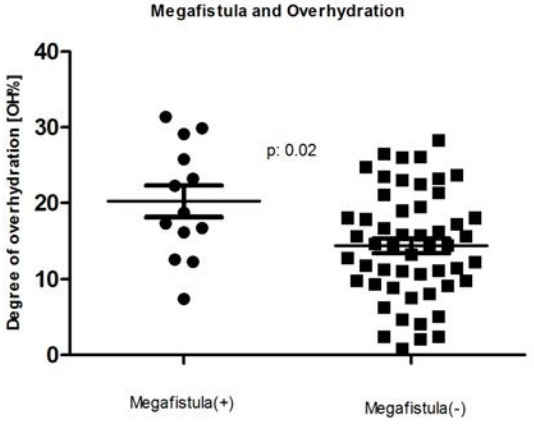
FR-PO720

The Association of Overhydration Status with Megafistulas in End-Stage Renal Disease Patients on Hemodialysis Mihaly B. Tapolyai,[1] Maria Faludi,[1] Melinda Forró,[1] Andras Tisler,[2] Tibor Fulop,[3] Klara Berta.[1] *[1]Dialysis, Fresenius Medical Care Semmelweis Univ, Budapest, Hungary; [2]Nephrology, Semmelweis Univ, Budapest, Hungary; [3]Nephrology, Univ of Mississippi, Jackson, MS.*

Background: Megafistulas are tortuous dilated fistulas that fold up on themselves and become visible on the arm and shoulders all the way to the clavicles. They may exacerbate low cardiac output, as well as represent a problematic dilatation of the dialysis access. We sought to investigate the association of bioimpedance apparatus (BCM) measured extracellular fluid volume overhydration (OH%) and the presence of megafistulas.

Methods: In a cross sectional study we compared the pre-dialysis BCM-measured OH% in 12 prevalent chronic dialysis patients with megafistulas (MEGA) who had negative angiographies with that of 52 control dialysis patients (CONTR).

Results: 10/12 MEGA patients had OH% >/=16% as compared to 20/52 CONTR patients (Chi square p: 0.02).



The degree of OH% was 20.2 ±7.4% among the MEGA vs. 14.4 ±7.1% in the CONTR group (Student t p: 0.01), representing 4.2 ±3.2 vs 2.8 ±1.6 L of excess fluid (p: 0.03). MEGA patients took an average of 1.7 ±1.4 vs. 0.8 ±0.8 (p: 0.002) antihypertensive medications compared to the CONTR patients yet their blood pressure was 156/91 vs 141/78 mmHg (p: 0.03/<0.0001). We found no difference in fistula vintage, body mass index, age, inflammatory markers, diabetes status or diuretic use. The odds ratio of overhydration being associated with a megafistula is 5.3 (p: 0.01).

Conclusions: There is an association of BCM-measured overhydrated clinical state with the presence of megafistulas; either as an increased volume capacitance or as a potential cause.

FR-PO721

The Observation of the Tunneled Cuffed Catheter Insertion Through Right Innominate Vein in Hemodialysis Patient Yanhuan Feng, Tianlei Cui, Ping Fu. *Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.*

Background: The routine vascular access for hemodialysis is often available due to thrombosis and occlusion after frequent cannulation, which leads to an increase in cost and difficulty of catheterization or recanalization. Further catheterization may accelerate exhaustion of vascular resources. We inserted cuff catheter through right innominate vein in patients with thrombosis or occlusion of right internal jugular vein and subclavian vein so as to preserved precious vascular access at other parts of body. Here we report our observation of right innominate vein catheterization.

Methods: We enrolled patients who had been receiving regular HD in our center and to whom catheter cannot be inserted due to thrombosis or occlusion of internal jugular vein and subclavian vein. We performed cuff catheter insertion by puncturing right innominate vein in 8 patients and recorded their clinical features, lesion position, and efficacy of the treatment.

Results: Among the 8 cases, where mean age is 67.6 years (range from 54-78), 3 of them are male and 5 are female. All the patients received central venous catheterization for more than 2 times, with median time of having a catheter for 36 months. The vascular ultrasound and CTA reveals that all of them suffered thrombosis or occlusion of right internal jugular vein and subclavian vein. By puncturing right innominate vein, all the patients' vascular accesses have been successfully established, with the end of cuff catheter located in the right atrium, superior vena cava(SVC) or SVC/ right atrial junction. No obvious discomfort has been reported, nor did complications such as hematoma and pneumothorax recorded. The mean follow-up period lasts for 12 months, all vascular access of these cases are patency.

Conclusions: For HD patients with limited vascular resources such as thrombosis or occlusion of right internal jugular vein and subclavian vein, the application of tunneled cuffed venous catheter through innominate vein has been proved to be safe and effective. It could preserve vascular access by bypassing the stenotic lesion internal jugular vein or subclavian vein, and reduce the incidence of vascular access exhaustion.

FR-PO722

Tunneled Hemodialysis Catheter and Hemodialysis Outcomes Vedran Pasara, Mladen Knotek. *Dept of Medicine, Renal Div, Univ of Zagreb, Merkur Hospital, Zagreb, Croatia.*

Background: Studies have reported that tunneled dialysis catheter (TDC) is associated with inferior hemodialysis (HD) patient (pt) survival, as compared to arteriovenous fistula (AVF). Since many cofactors may also affect survival of HD pts, it is unclear whether the risk for the worse survival arises from TDC *per se,* or from associated conditions. Therefore, the aim of this study was to determine the long-term outcome of HD patients, with respect to vascular access (VA).

Methods: Thisretrospective case-control studyincluded all 156 pts with TDC placed from 2010 to 2012 at Clinical Hospital Merkur. Control group consisted of 97 pts dialyzed through AVF. The groups were matched according to dialysis unit and time of VA placement. The site of choice for the placement of TDC was right jugular vein. Kaplan-Meier analysis with log-rank test was used to assess pt survival. A multivariate Cox regression analysis was used to determine independent variables associated with the pt survival.

Results: Cumulative one-year survival of pts who were dialyzed exclusively through TDC was 86.4 % and of those who were dialyzed exclusively through AVF the survival was 97.1 % (p=0.002). In a multivariate Cox regression analysis, male sex and older age were independently negatively associated with the survival of HD pts, while shorter duration of HD before the creation of the observed VA, hypertensive renal disease and glomerulonephritis were positively associated with survival. TDCturned to be an independent negative risk factor for survival of HD pts (HR 23.037, 95% CI 6.221-85.308).

	TDC	AVF	p
Patient age at the initiation of HD (yrs)*	62.08±14.39	63.85±13.23	0.215
Patient age at current VA creation (yrs)*	63.69±14.20	64.01±13.39	0.737
Sex (m/f)	88/68	64/33	0.081
HD vintage (days)**	658 (374, 1114)	536 (320, 1139)	0.836
Diabetes mellitus	44.2%	40.2%	0.464
Coronary artery disease	20.5%	20.6%	0.851
Cerebrovascular disease	16.7%	4.1%	0.001
Peripheral vascular disease	19.9%	20.6%	0.902
*mean ± SD; ** median with IQR			

Conclusions: TDC is an independant negative risk factor for the survival of patients on HD.

Funding: Government Support - Non-U.S.

FR-PO723

Carpal Tunnel Syndrome Is Associated with Arteriovenous Fistula in Hemodialysis Patients Il Young Kim,[1] Min Jung Kim,[1] Joo Hui Kim,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Su Min Park,[2] Jong Man Park,[2] Woo Jin Jung,[2] Sang Heon Song,[2] Eun Young Seong,[2] Harin Rhee,[2] Ihm Soo Kwak.[2] *[1]Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea; [2]Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea.*

Background: Carpal tunnel syndrome (CTS) is associated with various systemic diseases such as rheumatoid arthritis, hypothyroidism, peripheral neuropathy and diabetes mellitus (DM). In hemodialysis patients, several factors can contribute to CTS, including amyloid deposition, generalized fluid retention, increased synovial volume, edema around the nerve, and an ischemic or 'steal' effect distal to a dialysis access. This study aimed to evaluate the influence of arteriovenous fistula (AVF) dysfunction on the development of CTS.

Methods: The study included 43 patients (23 male & 20 female) on maintenance hemodialysis via AVF and 97 healthy controls. The median nerves of study population were examined by ultrasonography. Cross-sectional area (CSA) of the median nerve was measured at the distal wrist (CSA-D), and proximal forearm (CSA-P), and wrist-to-forearm ratio (WFR; CSA-P/CSA-D) was calculated for each hand. We also investigated the history of percutaneous transluminal angioplasty (PTA) in them.

Results: The mean age of hemodialysis patients was 60.4 ± 16.0 years. The mean duration on hemodialysis was 48.3 ± 39.6 months. The WFRs in hemodialysis patients were higher than those in healthy controls (1.37 ± 0.45 vs. 1.21 ± 0.25, $P < 0.05$). The hands with AVF (n = 43) showed higher WFR than those without AVF (n = 43) in hemodialysis patients (1.35 ± 0.47 vs. 1.25 ± 0.26, $P < 0.05$). The WFRs in patients with a history of PTA were higher than those in patients without a history of PTA (1.46 ± 0.56 vs. 1.23 ± 0.32, $P < 0.05$).

Conclusions: In maintenance hemodialysis patients, WFR of median nerve was significantly increased in the hand with AVF. Moreover, development of CTS was related not only to AVF itself, but also to AVF function.

FR-PO724

Factors Affecting Patency of Haemodialysis Arterio-Venous Fistulae and Grafts Ayesha Irtiza-Ali, Salman Ahmed, Nicola Ding, Joseph Russell, Nihil Chitalia, Maggi Steele, Hannah R. Wilson, David Makanjuola. *Renal Unit, St. Helier Hospital, Carshalton, United Kingdom.*

Background: Arterio-venous fistulae (AVF) are the preferred access for haemodialysis (HD), and where these cannot be created, arterio-venous grafts (AVGs) are the next best option. AVFs/AVGs however, not uncommonly fail to mature. The causes of this are varied, but loss of patency due to thrombosis and/or significant stenoses are major causes. We investigated the factors affecting patency of AVFs/AVGs in order to identify whether there were any characteristics which were predictive of this.

Methods: All AVFs/AVGs created in our unit between 2006 and 2014 were reviewed. Reasons for loss of primary patency were obtained from the dialysis access database. Characteristics reviewed were age, gender, co-morbidity score, diabetes status and site of AVF. Patients were grouped as follows: patency <30 days, patency <90 days, patency >90 days and patency >365 days.

Results: There were 1897 () AVFs and 251 () AVGs created. 649 (34.2%) of AVFs were lower arm, all the AVGs were upper arm, or lower limb. 1346 (62%) were male. The main reasons for AVF loss were clotted/stenosed vessels in 76% of cases. There was no association between ethnicity or gender with regard to patency rates. Other variables are shown in table 1.

Variable	<30 days	<90 days	>90 days	>365 days
AVF % patent	88%	70%	70%	39%
Age (mean)	72 years	72 years	70 years	71 years
AVG % patent	88%	75%	62%	35%
Age (mean)	70.5 years	70.5 years	66.8 years	67.1 years
Diabetic	31%	36%	35%	34%
Davies Co-morbidity score				
0 (no co-morbidities)	17.3%	13.1%	14.4%	14.3%
1 (1-2 co-morbidities)	60.3%	62.3%	60.9%	64.2%
2 (3 or more co-morbidities)	11%	13.1%	13.8%	13.0%

Conclusions: We did not find any definite predictive factors for loss of primary patency in the variables we studied. In particular, co-morbidity score, age and diabetes showed no association with poorer outcomes. There is quite a significant 'drop off' in primary patency at 12 months. In the majority of cases, this was due to thrombosis of the HD access. This highlights the importance of close surveillance, as measures to maintain patency (surgical or radiological) are more likely to be required in this period.

FR-PO725

Drug-Eluting Stents versus Bare-Metal Stents During Percutaneous Coronary Intervention in Patients on Dialysis Tara I. Chang,[1] Maria E. Montez-Rath,[1] Mark A. Hlatky,[1] Wolfgang C. Winkelmayer.[2] *[1]Stanford; [2]Baylor College of Medicine.*

Background: In patients undergoing percutaneous coronary intervention (PCI), drug-eluting stents (DES) reduce the need for repeat revascularization (RR) compared with bare-metal stents (BMS). The effects on death and MI are more controversial, with mixed results from observational studies and generally null results from clinical trials. However, few previous studies have focused patients with end-stage renal disease (ESRD). We compared the effectiveness of DES with BMS in a representative cohort of US patients on dialysis.

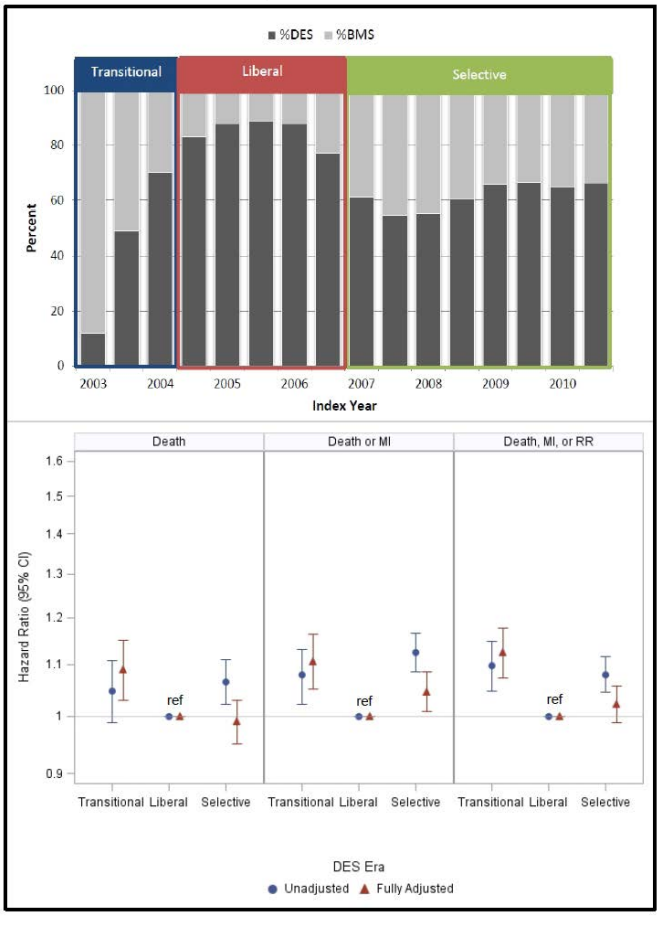
Methods: Using the US Renal Data System, we identified 36,117 patients on dialysis with Medicare Parts A+B who had PCI with stenting after DES became available in the US (4/23/03 – 12/31/10). We used propensity-score matching (PSM) and inverse probability of treatment weighting (IPTW) with Cox regression to examine the association of DES versus BMS on the following 1-year outcomes: death, death or MI, and death, MI or RR. Due to concerns about residual indication bias, we conducted a second, temporal analysis that leveraged the large changes in the prevalence of DES use during three distinct eras: Transitional (4/23/03 -6/30/04); Liberal (7/1/04 – 12/31/06); and Selective (1/1/07 – 12/31/10).

Results: In the PSM and IPTW analyses, DES was associated with lower risks of all three outcomes compared with BMS.

Table: Hazard ratios (95% CI) for DES vs BMS

	Death	Death/MI	Death/MI /RR
PSM	0.82 (0.78-0.86)	0.84 (0.91-0.87)	0.87 (0.84-0.91)
IPTW	0.82 (0.79-0.85)	0.85 (0.82-0.87)	0.88 (0.85-0.90)

DES use varied by era: Transitional=56%, Liberal=85%, and Selective=62%. In the temporal analysis, outcomes in the Liberal DES era were significantly better than in the Transitional Era, but not consistently better than in the Selective Era.



Conclusions: Adoption of DES for PCI was associated with improved outcomes in US patients with ESRD on dialysis.

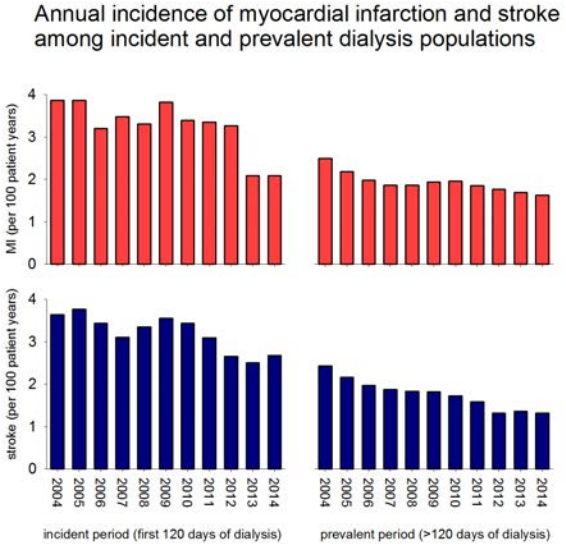
Eleven Year Trends in Myocardial Infarction and Stroke in the Incident and Prevalent Dialysis Population Kevin Chan,[1] Len A. Usvyat,[1] Ann Mooney,[1] Dugan Maddux,[1] Karen G. Butler,[1] Sophia Zhao,[2] Franklin W. Maddux.[1] *[1]Medical Office, Fresenius Medical Care North America, Waltham, MA; [2]Div of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Myocardial infarction (MI) and cerebrovascular (CVA) events are highly prevalent in the chronic dialysis population. We aimed to quantify the annual incidence and trends of MI and CVA events from 2004 to 2014 in a large dialysis population.

Methods: We analyzed >600,000 patients receiving chronic dialysis from a large dialysis provider from January 2004 to December 2014. For each calendar year, we calculated the incidence of MI and CVA (event per 100 patient years) identified by ICD9 code for the population in the first 120 days of chronic dialysis (incident period) and in the subsequent period after the first 120 days (prevalent period). Linear regression was used to quantify statistically significant trends in MI and CVA rate of the eleven year period.

Results: Over an eleven year period in the incident population, the mean incidence of MI and CVA was 3.3 and 3.2 events per 100 patient years respectively. Among the prevalent population, the mean incidence of MI and CVA was 1.9 and 1.8 events per 100 patient years respectively. Using linear regression models, the incidence of MI and CVA was found to decrease by 0.14 (p=0.005) and 0.11 (p=0.0009) per year among incident patients. Similarly, the incidence of MI and CVA was found to decrease by 0.06 (p=0.0007) and 0.10 (p<0.0001) per year among prevalent patients. See Figure 1.



Conclusions: Both MI and CVA rates are decreasing among incident and prevalent dialysis populations over the past eleven years.

FR-PO727

Relationship of Ticagrelor Dose and Platelet Reactivity in Patients with End Stage Renal Disease on Hemodialysis Jin sug Kim, Tae won Lee, Chun-Gyoo Ihm, Sang ho Lee, Se yun Kim, Shin yeong Lee, Yu ho Lee, Kyung-hwan Jeong. *Internal Medicine, KyungHee Univ School of Medicine, Seoul, Korea.*

Background: In our previous study, ticagrelor has superiority on platelet inhibition than clopidogrel in patients with end stage renal disease(ESRD) on hemodialysis(HD). One study compared two doses of ticagrelor(90 or 60mg) and placebo, reported that ticagrelor significantly reduced the risk of cardiovascular death, MI, or stroke and increased the risk of bleeding. The rate of bleeding is more frequent in 90mg group. We hypothesized there was some relationship between ticagrelor dose and platelet inhibition. We investigated efficacy and safety of standard and low dose ticagrelor, and clopidogrel in ESRD patients on HD.

Methods: In a single-center, prospective, randomized study, 50 ESRD patients were randomly assigned to receive clopidogrel(75mg once daily), standard dose ticagrelor(90mg twice daily) or low dose ticagrelor(90mg once daily) for 14days. Platelet function assessment which included transmittance aggregometry, and VerifyNow TM P2Y12 assay were then used to serially measure. Maximal platelet aggregation (MPA), inhibition of platelet aggregation (IPA), and P2Y12 reaction units (PRUs) were evaluated.

Results: Baseline characteristics, and concomitant medication of three groups were not significantly different. The standard dose ticagrelor showed significant lower MPA and higher IPA as compared with clopidogrel at 1,5,and 48 hours, and 14days after (p<0.05). Low dose ticagrelor showed significant lower MPA and Higher IPA at 5hours after(p<0.001). Although there was no statistical significance, after 1,48hours and 14days revealed lower MPA and higher IPA, as compared with clopidogrel. There was no significant difference between two ticagrelor doses. Two doses of ticagrelor showed significant lower PRUs, as compared with clopidogrel(p<0.001). 2 patients of standard dose ticagrelor and 1 patient of clopidogrel discontinued study because of bleeding. There was no bleeding in low dose ticagrelor.

Conclusions: Low dose ticagrelor may result in greater platelet inhibition than clopidogrel in ESRD patients on HD. Further studies with large number and various doses of medicine are needed.

FR-PO728

Prognostic Accuracy of Serial versus Single Troponin Measurements in Hemodialysis Patients Thomas A. Mavrakanas,[1,2] Allan Sniderman,[3] Ahsan Alam.[1] *[1]Div of Nephrology, McGill Univ Health Center, Montreal, QC, Canada; [2]Div of General Internal Medicine, Geneva Univ Hospitals, Geneva, GE, Switzerland; [3]Div of Cardiology, McGill Univ Health Center, Montreal, QC, Canada.*

Background: Cardiac troponin I (TnI) elevation in stable patients receiving chronic hemodialysis (HD) is associated with increased mortality. The frequency of measuring TnI to determine risk is not yet known. This study aimed to assess whether using serial TnI measurements improves the predictive accuracy for mortality compared with a single measurement.

Methods: Pre-dialysis TnI levels were measured in 130 stable HD patients monthly for 3 consecutive months. A value above the laboratory reference range (>0.06 mg/L) was considered to be elevated. To assess the prognostic accuracy of TnI measurement, three different approaches were used to determine high risk: i) only the first month's value was elevated; ii) at least one of three monthly TnI values were elevated; iii) at least two of the three monthly TnI values were elevated. All the patients were followed-up for 12 months. Multivariate Cox proportional hazard analysis was used to examine the association of TnI elevation with the outcomes of mortality or a composite of mortality with major cardiovascular events. The performance of each TnI classification method was compared using net reclassification index (NRI).

Results: Of 130 patients, 36 had an elevated TnI in the first month, 44 had at least one elevated TnI value, and 26 had 2-3 elevated TnI values. The composite outcome was significantly higher in patients with an elevated TnI compared with patients who had normal TnI levels, regardless of the method used [HR i) 3.66 (1.76-7.63) ii) 3.55 (95%CI 1.68-7.52) iii) 3.81 (95%CI 1.83-7.94)]. Similar associations were seen with the outcome of mortality alone. Patients classified as high risk using at least one elevated serial TnI measure, were associated with a NRI of 0.035, as compared with a single TnI measurement. If patients were classified as high risk using at least two elevated TnI values, the NRI was -0.072.

Conclusions: Serial TnI measurements are associated with only marginal improvement in predicting mortality or MACEs as compared with a single TnI measurement.

Funding: Government Support - Non-U.S.

FR-PO729

High Ultrafiltration Rates Are Associated with Increased Troponin Levels in Stable Hemodialysis Patients Thomas A. Mavrakanas,[1,2] Allan Sniderman,[3] Murray L. Vasilevsky,[1] Ahsan Alam.[1] *[1]Div of Nephrology, McGill Univ Health Center, Montreal, QC, Canada; [2]Div of General Internal Medicine, Geneva Univ Hospitals, Geneva, GE, Switzerland; [3]Div of Cardiology, McGill Univ Health Center, Montreal, QC, Canada.*

Background: An elevated troponin level in asymptomatic patients on hemodialysis is associated with a higher risk of mortality and cardiovascular events. The underlying mechanism for this association has not been elucidated. The objective of this study was to assess whether intra- and inter-dialytic parameters are associated with higher troponin I (TnI) levels.

Methods: Stable chronic hemodialysis patients at 2 tertiary care centers were enrolled in this study. Pre-dialysis TnI levels were measured with monthly bloods for three consecutive months. TnI was measured by immunoassay and was considered to be elevated if it exceeded the laboratory reference range (0.06 mg/L). We examined the association of the dialysis vintage, session duration, intradialytic hypotension (IDH), high ultrafiltration rate (UFR), defined as a UFR $\geq$ 12.4 ml/kg.h, and interdialytic weight gain (IDWG) using a mixed linear fixed effects model for repeated measures.

Results: 236 patients were enrolled in the study: mean age 67.5 years old, 56% male, 47% had diabetes and 28% had pre-existing coronary artery disease. There were 88 elevated TnI values (13% of all measured) in 52 patients. In univariate analysis, high UFR and dialysis vintage, but not IDH or IDWG, were associated with TnI variability. In multivariate analysis, both high UFR (p=0.02) and dialysis vintage (p=0.01) explained TnI variability. The intraclass correlation coefficient was found to be 1%, suggesting that the observed variability is within and not between subjects, with session related parameters being more important than inter-individual differences.

Conclusions: In this observational study we identify potentially modifiable factors associated with TnI elevation. Strategies to prevent hemodialysis-induced myocardial injury may include efforts to avoid excessive ultrafiltration, minimize IDWG, or offer more frequent dialysis, but these need to be validated by interventional studies.

FR-PO730

Prognostic Value of High-Sensitivity Troponin T in Stable Dialysis Patients Titi Chen, Angela Makris. *Dept of Nephrology, Liverpool Hospital, Liverpool, New South Wales, Australia.*

Background: We evaluated the prognostic value of high-sensitivity cardiac troponin T (hs-TNT) in predicting myocardial infarction (MI) and death in dialysis patients after 4 years.

Methods: A retrospective review of a cohort of 354 hemo- (HD, 254) and peritoneal-dialysis (PD, 109) patients was followed up to 4 years after baseline hs-TnT. All-cause mortality, cardiac mortality and new MI were assessed.

Results: The median hs-cTNT was 60 ng/L (interquartile range IQR 38-105 ng/L) with no observed difference between HD and PD patients (P=0.18). Patients dying (n=148) had higher baseline hs-TNT (median 90 vs 50 ng/L, P<0.001). Similar trends were observed for both HD and PD subgroups. Patients with cardiac mortality (n=25) had higher baseline hs-TNT compared with non-cardiac mortality (121 vs 75.5 ng/L, P=0.013). These trends were only observed in the HD subgroup. Patients with a new MI (n=65) had no difference in their baseline hs-cTNT (66 vs 59 ng/L, P=0.064) compared to controls. The group was divided into quartiles based on hs-cTNT. Incremental increase in mortality (P<0.001), cardiac mortality (P<0.001) and MI (P=0.033) were observed with increasing hs-cTNT quartiles. Similar trends were observed for both HD and PD subgroups except MI in the HD subgroup. For every increase of 25 ng/L in hs-cTNT, the unadjusted hazard ratio (HR) was 1.094 for cardiac mortality (P=0.043, 95%CI 1.003-1.192), 1.123 for MI (P=0.000, 95%CI 1.053-1.198). The adjusted HR for MI was 1.107 (P=0.018, 95%CI 1.018-1.205). Kaplan-Meier curves demonstrated increasing hs-cTNT quartiles was associated with an increase in the incidence of cardiac mortality (P=0.014) and MI (P=0.013) but not overall mortality. 178 patients had hs-cTNT repeated at 4 years. There was a significant increase in hs-cTNT from a baseline of 60 ng/L (IQR, 38-105 ng/L) to a 4-year concentration of 64 ng/L (IQR, 42-104 ng/L) (P=0.000). This was true for both patients with (P= 0.008) or without (P<0.001) new MI. Similar trends were observed for both HD and PD subgroup analysis.

Conclusions: Hs-cTnT has a useful role in predicting all-cause mortality, cardiac mortality and MI in stable dialysis population. There was an increase in hs-cTNT level over a 4-year period.

FR-PO731

Temporal Trends in Myocardial Infarction Incidence and 30-Day Mortality in U.S. Dialysis Patients Charles A. Herzog,[1] Keri L. Monda,[2] Anne C. Beaubrun,[2] Wolfgang C. Winkelmayer,[3] Til Stürmer,[4] Allan J. Collins,[1] Akhtar Ashfaq,[2] Kenneth J. Rothman,[5] David T. Gilbertson.[1] *[1]Chronic Disease Research Group, MMRF; [2]Ctr for Observational Rsrch, Amgen; [3]Baylor College of Medicine; [4]UNC Gillings School of Global Public Health; [5]RTI Health Solutions.*

Background: Acute myocardial infarction (MI) is a catastrophic event in dialysis pts. Few data exist on current MI hospitalization rates. We assessed trends in type of MI (ST-elevation MI [STEMI], non-ST-elevation MI [NSTEMI], and unclassifiable MI [other]), and death rates by type of MI in 2005-2011.

Methods: Using Medicare claims data, we created yearly cohorts of dialysis pts point prevalent on January 1 of each year 2005-2011. We assessed STEMI, NSTEMI, and other MI hospitalization rates, and calculated annualized 30-day death rates following MI.

Results: In 2005 there were 10,275 NSTEMI, 1,892 STEMI, and 1,918 other MI vs 2011 16,235 NSTEMI, 1,269 STEMI, and 1,634 other MI. Demographics: mean age 67; 5% < 45, and 6% > 84 yrs; 47% female; 48% white, 32% black; 55% ESRD from DM. While overall MI rate increased slightly from 2005-2011 (80.1 /1,000 PY in 2005 vs 91.2 in 2011), STEMI and other MI decreased by 44% and 29% respectively, while NSTEMI increased by 31%. Short term mortality was relatively unchanged for NSTEMI (295 deaths/1000 PY), increased slightly for STEMI (495/1000 PY in 2005 to 565/1000 PY in 2011), and was highest following other MI (881/1000 PY in 2005 and 915/1000 PY in 2011).

Conclusions: In the recent treatment era there has been little change in either rates of overall MI hospitalization or 30-day mortality. The increase in NSTEMI rates may be due to greater utilization of more sensitive cardiac biomarkers (cardiac troponins) for MI diagnosis. MI remains a catastrophic event for dialysis pts. Aggressive interventions to reduce the burden of ischemic heart disease and to improve its prognosis in dialysis pts are warranted.

FR-PO732

Risk of Acute Coronary Events and Coronary Interventions for Overweight and Obese Patients versus Normal Weight Patients Undergoing Dialysis – A National Study Austin G. Stack,[1,2,3] Mohamed Elsayed,[1,2] Muhammad Umair Sharif,[1,2] John P. Ferguson.[2] *[1]Nephrology, Univ Hospital Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland; [3]Health Research Inst, Univ of Limerick, Ireland.*

Background: Although elevated body mass index (BMI) is associated with increased risk of cardiovascular events in the general population, it is suggested that the converse may hold true for patients on dialysis.

Methods: We tested this hypothesis in a national cohort of 1,072,737 incident Medicare-eligible US patients, who began dialysis between 5/1995 and 12/2008. Hospitalizations attributed to first myocardial infarction (MI) [ICD 9 codes; 410] and major coronary interventions (coronary angioplasty, stent, and coronary bypass surgery) following first MI were obtained from the US Renal Data System. Multivariable Cox regression compared hazard ratios [HR] of MI and subsequent coronary interventions among BMI categories.

Results: The adjusted HR of MI was highest for underweight patients and lowest for morbidly obese patients, decreasing significantly with increasing BMI category. Overweight patients were significantly more likely to receive a coronary intervention post-MI compared to normal weight individuals but this benefit did not extend to morbidly obese or underweight patients.

		HR of MI	HR of Intervention Post STEMI	HR of Intervention post Non-STEMI
BMI Category (Kg/m^2)	N (%)			
Underweight (< 18.5)	58, 659 (5.7)	1.04 (1.00-1.08)	0.79 (0.56-1.12)	1.00 (0.82-1.24)
Normal (18.5-25)	380, 587 (37.0)	1.00	1.00	1.00
Overweight (25-30)	290, 542 (28.3)	0.96 (0.94-0.98)	1.31 (1.11-1.54)	1.17 (1.06-1.29)
Class I Obesity (30-35)	159, 895 (15.6)	0.90 (0.87-0.92)	1.24 (1.01-1.52)	1.01 (0.89-1.15)
Class 2 Obesity (35-40)	75, 823 (7.4)	0.85 (0.82-0.88)	1.20 (0.91-1.59)	1.05 (0.89-1.26)
Class 3 Obesity (> 40)	63, 027 (6.1)	0.84 (0.81-0.88)	1.04 (0.74-1.45)	0.89 (0.72-1.10)

Conclusions: In contrast to the general population, higher BMI is associated with lower risk of major coronary events in US dialysis patients suggesting a protective effect. Furthermore, access to coronary interventions following a major coronary event is not equal across BMI categories.

Funding: Government Support - Non-U.S.

FR-PO733

Propensity-Based Comparison of Haemodialysis and Peritoneal Dialysis with Risk of Haemorrhagic and Ischaemic Stroke Among New Dialysis Patients Austin G. Stack,[1,2,3] Mohamed Elsayed,[1,2] Muhammad Umair Sharif,[1,2] John P. Ferguson.[2] *[1]Nephrology, Univ Hospital Limerick, Ireland; [2]Graduate Entry Medical School, Univ of Limerick, Ireland; [3]Health Research Inst, Univ of Limerick, Ireland.*

Background: The risk of stroke is between 6-10 fold higher in dialysis patients compared to the general population. It is hypothesised that the choice of dialysis modality at initiation may influence the risk of stroke.

Methods: We tested this hypothesis in a national cohort of 1,097,747 US patients (n=86,168 on PD) who were Medicare eligible and began dialysis between 5/1995 to12/2010 and followed until 9/2011. Hospitalizations attributed to first Haemorrhagic Stroke (H-CVA) and Ischaemic stroke (I-CVA) were obtained from the US Renal Data System files and merged with data from the medical evidence, treatment history and mortality files. Multivariable Cox regression compared the hazards ratio [HR] of H-CVA and I-CVA for PD versus HD with a propensity-matched intent-to-treat (ITT) approach and as-treated analysis. Patients were censored at transplantation, death, recovery of kidney function, or end of study (Sept1 2011). Approval was received from University Hospitals Ethics Committee.

Results: The adjusted PD/HD HRs for first hospitalized H-CVA using the intent-to-treat model was 0.89 (0.83,0.95) and this decreased from 0.73 (0.61,0.87) in the period 1995-1998 to 0.64 (0.51,0.80) in the period 2007-2010. In contrast, overall HRs for I-CVA were 1.15 (1.12-1.18) and this decreased from 1.20 (1.13-1.27) in the period 1995-1998 to 1.06 (0.97-1.15) in the period 2007-2010. The as-treated model suggested more favourable outcomes for H-CVA with overall HR of 0.61 (0.57,0.67) and for I-CVA with a HR 0.96 (0.93-0.99) in 2007-2010 period. Patients who switched from PD to HD or HD to PD had significantly higher HR of H-CVA, while patients who switched from PD to HD had higher HR of I-CVA.

Conclusions: PD and HD contribute differentially to the overall risk of I-CVA and H-CVA among new dialysis patients. While PD is similar to HD with regard to hazards of I-CVA, it appears to protect against the hazard of H-CVA. These associations should be taken into consideration when choosing treatment options for new dialysis patients.

FR-PO734

Predictors of Sudden Cardiac Death in Hemodialysis Patients with and without Previous Arrhythmia – Results from a Multinational Cohort
Viviane Calice-Silva,[1] Stephan Thijssen,[2] Xiaoling Ye,[2] Aileen Grassmann,[3] Daniele Marcelli,[3] Bernard J. Canaud,[3] Peter Kotanko,[2] Roberto Pecoits-Filho.[1] *[1]Pontifícia Univ Católica do Paraná, Brazil; [2]Renal Research Inst; [3]Fresenius Medical Care, Germany.*

Background: Cardiac dysfunction, rapid electrolyte shifts and high ultrafiltration rates during hemodialysis (HD) are associated with increased vulnerability to arrhythmogenic events. Patients with previous arrhythmia(ARR) are at a higher risk of sudden cardiac death (SCD – Herzog et al, 2011). Our aim was to analyze predictors of SCD in HD patients with and without previous ARR.

Methods: Incident HD patients from the Monitoring Dialysis Outcomes (MONDO) cohort who received in-center treatment between 1/2006-12/2011 and survived at least 90 days on HD were included and followed until 12/2012. Causes of death were classified as SCD according ICD-10/ICD-9. Patients with comorbidity or prior hospitalization due to ARR and/or ARR predisposition were identified. Cox proportional hazards models were constructed to explore associations between baseline parameters and SCD.

Results: We studied 19,129 patients (16 countries). 7,538 patients with complete data were included in the models, 613 died of SCD. Mean age 62.7(±15.5)years, 58.1% male, 48.4% diabetics. Age, ischemic heart disease, albumin, serum sodium, interdialytic weight gain in % of post-HD weight and pre-HD-systolic blood pressure were identified as predictors of death in both subgroups. Distinct predictors are shown below.

Table 1: Predictors of SCD in patients with (N=158) and without ARR history and/or predisposition (N=455).

Parameter	SCD with ARR	
	Hazard Ratio(±SE)	**P-value**
Serum bicarbonate [mmol/L]	0.07(0.04)	0.04
Leukocytes [1000/mm^3]	0.023(0.005)	<.0001
	SCD without ARR	
Hemoglobin [g/dL]	-0.11(0.04)	0.005
Dialysate sodium [mmol/L]	0.093(0.03)	0.0008
Catheter as vascular access	0.41(0.1)	<.0001

Conclusions: Despite the small sample size, some predictors of SCD seem to differ depending on the presence or absence of arrhythmia history or predisposition. These findings may assist the identification of patients at high risk for SCD. Further studies have to be done to corroborate these results.

FR-PO735

The Risks of Acute Health Events After Incident Atrial Fibrillation in Older Hemodialysis Patients
Medha Airy,[1] Benjamin A. Goldstein,[2] Mark A. Hlatky,[3] Nisha Bansal,[4] Alan S. Go,[5] Wolfgang C. Winkelmayer.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Duke Univ, Durham, NC; [3]Stanford Univ, Palo Alto, CA; [4]Univ of Washington, Seattle, WA; [5]Kaiser Permanente Northern California, Oakland, CA.*

Background: Limited data exist about whether incident atrial fibrillation/flutter (AF) impacts the risks of major acute health events in patients with ESRD undergoing hemodialysis (HD).

Methods: From the US Renal Data System, we studied older (≥67 years) adults with ³2 years of uninterrupted Medicare A&B coverage before starting HD (2006-11) and no known AF prior to ESRD. Incident AF was ascertained from ICD-9 diagnosis codes (427.3x) in inpatient claims. We used extended Cox regression adjusted for sociodemographic characteristics and key comorbidities to estimate hazard ratios (HR [95% confidence intervals]) for death, ischemic stroke, myocardial infarction (MI), and hip fracture (as a negative control outcome). AF was treated as a time-varying covariate, with time since first AF diagnosis further categorized as £30, 31-90, and >90 days. Patients were censored at time of kidney transplant or end of data (12/31/2011).

Results: We identified 85,377 eligible HD patients; 16.7% developed incident AF and 58.2% died during follow-up. Incident AF was associated with higher adjusted mortality: 8-fold higher during the first 30 days (HR=8.2 [7.9-8.6]), 4-fold higher between 31-90 days (HR=4.2 [4.0-4.4]), and 2-fold higher beyond 90 days after AF diagnosis (HR=2.2 [2.1-2.2]). Incident AF also increased the adjusted rate of ischemic stroke 1.5-2.5-fold: during the first 30 days (HR=2.1 [1.6-2.7]), 31-90 days (HR=2.5 [2.0-3.0]), and beyond 90 days (HR=1.5 [1.3-1.7]). Quantitatively similar findings were obtained for MI. However, the adjusted rate of hip fracture was only marginally increased following AF diagnosis (<=30 days: 1.1 [0.7-1.6]; 31-90 days: 1.4 [1.0-1.8]; >90 days: 1.2 [1.1-1.4]. All associations were attenuated when requiring incident AF to be indicated as principal discharge diagnosis.

Conclusions: While AF was independently associated with higher risks of ischemic stroke, MI, and hip fracture in older ESRD patients on HD, it was more strongly associated with excess all-cause mortality.

FR-PO736

The CRASH-ILR Study: Half a Million Hours of Continuous ECG Monitoring in a Hemodialysis Population
Robert Lewis,[1] Darren Green,[2] Philip A. Kalra,[2] Donah Zachariah,[3] Paul Kalra,[1] Paul R. Roberts.[4] *[1]Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom; [2]Salford Royal NHS Trust, Salford, United Kingdom; [3]Royal Bournemouth Hospital, Bournemouth, United Kingdom; [4]Southampton Univ Hospitals Trust, Southampton, United Kingdom.*

Background: Sudden cardiac death (SCD) may cause 25% of all hemodialysis (HD) patient deaths. Multiple potential mechanisms may contribute to the risk of life-threatening arrhythmias in this population. The CardioRenal Arrhythmia Study in Hemodialysis has continuously monitored patients using an Implantable Loop Recorder (ILR) for more than 500,000 hours.

Methods: 30 patients (60% male) aged 67±12 years on established HD for 39 ±44 months with varied etiology of CKD (diabetes 37%, hypertension 23%) and ejection fraction of 56±8% were implanted with a Reveal XT ILR (Medtronic, MN, USA). Patients transmitted data at each HD session and were asked to activate their ILR if symptomatic with palpitations, dizziness or syncope.

Results: Patients were monitored for an average of 17,810±8,108 hours performing 94±92 transmissions. 6 patients (20%) died during the study. The final arrhythmia was VF in 2 patients and agonal bradycardia in 3. One patient died from SCD 2 weeks after device explantation due to infection. All 3 bradycardic deaths occurred in patients during end-of-life care. 1 VF death occurred during a GI bleed: the other was unheralded. A surviving patient received a biventricular pacemaker for 2:1 block detected by ILR. Atrial arrhythmias (AA) were noted in 7 (23%), 4(13%) of which were incident. 1 patient had asymptomatic sustained VT managed with antiarrhythmic drugs. Frequent ectopy was recorded in 2 patients. There were 19 symptomatic activations in 6 patients all corresponding to sinus rhythm (or AA in cases of permanent AF). 6 patients had device explantation, 4 after renal transplantation and 2 due to device infection.

Conclusions: CRASH-ILR is the longest ILR follow up in HD patients to date and provides new insights into arrhythmia and SCD. Arrhythmias occurred in 15 (50%) of the study population. Mortality was high, but this was due to SCD as an expected end-of-life event in 5 of 6 patients.

Funding: Pharmaceutical Company Support - Medtronic, MN, USA

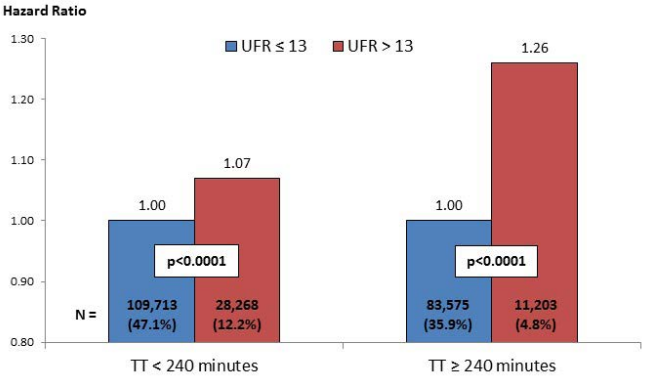
FR-PO737

Revisiting Ultrafiltration Rate (UFR), Treatment Time (TT) and Mortality in Thrice Weekly Hemodialysis
Jennifer L. Bragg-Gresham, Brett W. Plattner, Debabrata Ray, Yi Li, Rajiv Saran. *KECC, Univ of Michigan, Ann Arbor, MI.*

Background: UFR and TT are two potentially modifiable practices for improving outcomes in HD. UFR > 13ml/kg/hour has been associated with higher mortality. We re-examined this association, focusing on the effect of higher UFR at TT ≥ 4 hours, as longer TT has been claimed to be 'protective', even though TT > 4 hours is logistically difficult to implement in the prevailing US practice setting.

Methods: Using recently available national data from CROWNWeb (CW), we analyzed 232,759 adults on thrice-weekly, in-center HD. Baseline CW data was extracted from June 2012. Patients were followed through December 31, 2013. Cox regression was used to examine the association between UFR (calculated as the intradialytic weight loss / TT and expressed in ml/kg post HD-weight/hr) and mortality, adjusting for demographics, comorbidities, dialysis vintage, interdialytic weight gain (IDWG) and dialysis dose (Kt/V), stratified by TT. Average follow-up was approx 1 year.

Results: Individuals receiving TT ≥ 240 were younger, more likely to be black and male, and had larger BMI. In both strata of TT (< 240 and ³240) those patients with UFR >13 tended to be younger, non-black race, have a lower BMI, longer HD vintage, higher Kt/V, and higher IDWG than patients with UFR < 13. Congestive heart failure was more prevalent in patients with UFR ≤ 13 regardless of TT. In both strata of TT, patients with a UFR >13 had higher hazard of mortality, with a larger risk found in those with TT ≥ 240.



Conclusions: A higher UFR (>13) was associated with higher mortality irrespective of TT category. The association was surprisingly stronger among those receiving longer TT. In the US, longer TT is prescribedin order to achieve small solute targets (confounding-by-indication) and not necessarily to lower the UFR, as high UFR is a consequence of high IDWG and the average shorter TT.

FR-PO738

Sudden Death and Dialysate Potassium in Hemodialysis: Results from the Dialysis Outcomes and Practice Patterns Study (DOPPS)

Angelo Karaboyas,[1] Jarcy Zee,[1] Steven M. Brunelli,[2] Len A. Usvyat,[3] Daniel E. Weiner,[4] Franklin W. Maddux,[3] Allen R. Nissenson,[5] David C. Mendelssohn,[6] Michel Y. Jadoul,[7] Friedrich K. Port,[1] Bruce M. Robinson,[1,8] Francesca Tentori.[1,9]
[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]DaVita Clinical Research, Minneapolis, MN; [3]FMCNA, Waltham, MA; [4]Tufts Medical Center, Boston, MA; [5]DaVita Healthcare Partners, Inc., El Segundo, CA; [6]Humber River Regional Hospital, Toronto, Canada; [7]Univ Catholique de Louvain, Belgium; [8]U of Michigan, Ann Arbor, MI; [9]Vanderbilt U, Nashville, TN.

Background: Sudden death (SD) is common in hemodialysis (HD) patients. We investigated trends in dialysate (DK) and pre-dialysis serum (SK) potassium across the Dialysis Outcomes and Practice Patterns Study (DOPPS) phases 1-5 (1996-2015) and evaluated whether the risk of SD is higher with lower DK.

Methods: 67,263 patients in 21 countries were studied. Instrumental variable methods were used to model the effect of DK on SK. Adjusted Cox regression was used to test the associations of baseline DK and SK with all-cause death, and an arrhythmia composite (AC) of SD or arrhythmia-related hospitalization.

Results: In the US, DK and SK (mEq/L) have been stable over time (70% DK=2, 25% DK=3; mean±StdDev SK=4.7±0.7). In Europe, DK has increased (currently 15% DK=1-1.5, 45% DK=2, 33% DK=3) while mean SK has decreased from 5.2 to 4.9. SK was only 0.08 mEq/L higher per 1 mEq/L higher DK. SK ≥ 6 (ref 4.5-4.9) was associated with death (HR=1.12, 95% CI: 1.05-1.19) and AC (HR=1.17, 1.04-1.33). Compared to DK=2, DK=3 was not associated with death or AC, overall or at any level of SK (Fig).

Conclusions: In this large international cohort, SK was associated with elevated risk of SD, but risk of SD was similar for DK=2 or DK=3 across SK levels. Because DK had minimal influence on pre-dialysis SK, efforts to limit dietary K intake may be a more effective strategy to lessen the risks associated with high SK.

FR-PO739

Acute Health Events and the Risk of Incident Atrial Fibrillation in Older Patients Undergoing Maintenance Hemodialysis

Medha Airy,[1] Benjamin A. Goldstein,[2] Mark A. Hlatky,[3] Alan S. Go,[4] Nisha Bansal,[5] Wolfgang C. Winkelmayer.[1]
[1]Baylor College of Medicine, Houston, TX; [2]Duke Univ, Durham, NC; [3]Stanford Univ, Palo Alto, CA; [4]Kaiser Permanente Northern California, Oakland, CA; [5]Univ of Washington, Seattle, WA.

Background: Acute health events might increase the risk of developing atrial fibrillation (AF). We examined the incidence of new onset AF relative to several acute events in patients with ESRD initiating hemodialysis (HD).

Methods: From the USRDS, we studied older (67+ years) patients with 2 years of Medicare A&B coverage prior to initiating HD (2006-11) who had no documented diagnosis of AF, or claims indicating ischemic stroke, myocardial infarction (MI), or hip fracture prior to ESRD. We used time-varying Cox regression to estimate adjusted hazard ratios for incident AF relative to the acute events of interest, adjusted for socio-demographics and baseline comorbidities. The incidence of AF after either an acute stroke, MI, or hip fracture was modeled in time-varying fashion, during the periods of <=30, 31 to 90, and >90 days after the acute event. Patients were censored at kidney transplantation or end of database (12/31/2011).

Results: 85,377 older HD patients met the inclusion criteria. The risk of AF was approximately doubled in the 90 days after an ischemic stroke, and remained elevated thereafter (Table). The risk of AF after an acute MI followed a similar pattern, with highest risk in the 30 days after the MI. The risk of AF after hip fracture followed a slightly different pattern, peaking between 30 and 90 days after the event, with no significant late hazard after 90 days. These associations were essentially unchanged when requiring that the acute health event be reported as principal diagnosis.

Time since event:	Ischemic Stroke	Myocardial Infarction	Hip Fracture
<=30 days	2.1 (1.7-2.7)	2.9 (2.5-3.4)	1.5 (1.1-2.0)
30-90 days	1.9 (1.5-2.4)	2.3 (2.0-2.6)	2.1 (1.7-2.5)
>90 days	1.5 (1.3-1.6)	1.6 (1.5-1.7)	1.1 (1.0-1.3)

Conclusions: The risk of incident AF among patients on HD is increased after a stroke, MI, or hip fracture. Risks were highest in the first 90 days after the event, and remained elevated >90 days after an ischemic stroke or MI, but not after a hip fracture.

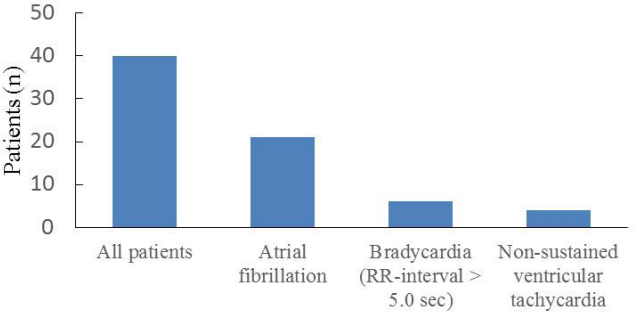
Arrhythmias as a Potential Cause of Dizziness and Syncope in Patients with End-Stage Renal Disease

Kati Kaartinen,[1] Jani Ahvonen,[2] Seppo Ojanen,[2] Joonas Markku Rautavaara,[5] Olli Anttonen,[2] Tuomas Kerola,[2] Kati Vaaraniemi,[3] Marja H. Miettinen,[3] Juhani Koistinen,[4] Atte Aitkoski,[5] Tuomo Nieminen.[5]
[1]Dept of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland; [2]Dept of Nephrology, Päijät-Häme Central Hospital, Lahti, Finland; [3]Dept of Nephrology, Central Hospital of Central Finland, Jyväskylä, Finland; [4]Dept of Cardiology, Vaasa Central Hospital, Vaasa, Finland; [5]Dept of Internal Medicine, Univ of Helsinki, Helsinki, Finland.

Background: It is unknown how often arrhythmias underlie dizziness and syncope in end-stage renal disease. We launched a study to implant subcutaneous loop recorders for their estimation.

Methods: Data is shown for 40 patients (62.4±8.2 years [mean±SD], range 39 to 78 y, 26 M) with stage 4 or 5 renal failure and f-u of > 2 months. Main kidney diseases were diabetic (18), polycystic disease (8) and chronic glomerulonephritis (6). One patient was pre-dialytic, five had peritoneal dialysis, and rest were on hemodialysis. Median time since the start of dialysis was 1.6 years. Seven patients (18%) had either chronic or paroxysmal atrial fibrillation (AF) prior to the implantation of the recorder, being in line with published data.

Results: During the f-u of 14±7 months, recorder revealed bradyarrhythmia in six (15%) patients with an R-R arrest of >5.0 sec with a max. of 9.0 sec; two patients with symptoms thus far received a pacemaker. AF occurred in 21 (53%) patients. The median time to detect new AF was 235 days. Four patients (10%) had non-sustained ventricular tachycardia unknown before the recorder data.



Conclusions: Arrhythmias are more typical than estimated in patients with severe kidney disease. Particularly, symptomatic bradycardia is relatively common and can be easily treated with a pacemaker. AF is three times more common than known before. These findings may change diagnostics and treatment of dizziness in these patients.

FR-PO741

Blood Pressure and Risk of Cardiovascular Events Among Hemodialysis Patients: The CRIC Study

Nisha Bansal,[1] Charles E. McCulloch,[2] Feng Lin,[2] Cassianne Robinson-Cohen,[1] Mahboob Rahman,[3] John W. Kusek,[4] Amanda Hyre Anderson,[5] Raymond R. Townsend,[5] Jackson T. Wright,[6] Alan S. Go,[7] Arnold B. Alper,[8] Radhakrishna Reddy Kallem,[5] Chi-yuan Hsu.[2]
[1]UW; [2]UCSF; [3]UH; [4]NIDDK; [5]UPenn; [6]Case Western; [7]KPNC; [8]Tulane.

Background: Among hemodialysis (HD) patients, previous studies have reported a U-shaped association between systolic blood pressure (SBP) and risk of mortality. However, the shape of the association between SBP and risk of cardiovascular events (CVD) is not well characterized.

Methods: We studied participants on HD in the Chronic Renal Insufficiency Study (CRIC). SBP was measured at the dialysis unit ("dialysis-unit-SBP", N=403) and at the CRIC study visit ("out-of-dialysis-unit SBP", N=326). We studied the association of SBP

with time to adjudicated CVD (defined as heart failure, myocardial infarction, peripheral vascular disease and stroke), adjusting for demographics, diabetes, smoking, BMI, prior CVD, kt/v, serum albumin and hemoglobin.

Results: Mean age was 60 (±11) years, 42% were women and 64% were Black. There were a total of 121 CVD events over a median time of 1.15 years. The association between dialysis-unit-SBP was U-shaped, with the greatest risk of CVD at the highest and lowest quartiles of dialysis-unit-SBP.

Table. Association between SBP and CVD events

	Unadjusted		Adjusted for patient characteristics + dialysis variables	
Dialysis-unit SBP (N=403)	HR (95% CI)	P value	HR (95%CI)	p value
Q1 SBP (< 138 mm Hg)	1.27 (0.77, 2.11)	0.4	1.26 (0.69, 2.31)	0.5
Q2 SBP(138- 150 mm Hg)	0.86 (0.50, 1.48)	0.6	1.06 (0.58, 1.91)	0.9
Q3 SBP (151 – 166 mm Hg)	Ref		Ref	
Q4 SBP (>166 mm Hg)	1.52 (0.94, 2.46)	0.09	1.73 (1.01, 2.96)	0.05
Out-of-dialysis-unit SBP (N=326)	HR (95% CI)	P value	HR (95%CI)	p value
Q1 SBP (< 113 mm Hg)	Ref		Ref	
Q2 SBP (113 - 128 mm Hg)	1.30 (0.69, 2.47)	0.4	1.40 (0.68, 2.88)	0.4
Q3 SBP (129 - 145 mm Hg)	2.02 (1.13, 3.62)	0.02	2.67 (1.37, 5.22)	0.004
Q4 SBP (>145 mm Hg)	1.98 (1.09, 3.62)	0.03	2.72 (1.35, 5.51)	0.005

Conversely, the association between out-of-dialysis-unit-SBP was linear, with the highest quartile having greater than 2-fold risk of CVD than the lowest quartile.

Conclusions: Among HD patients, the association of SBP measured in the dialysis unit with CVD is U-shaped, while the association of SBP measured outside the dialysis unit with CVD is linear, similar to what has been reported for mortality (Bansal et al, Hypertension 2015). Targeting SBP measured outside the dialysis unit may improve CVD outcomes in HD patients.

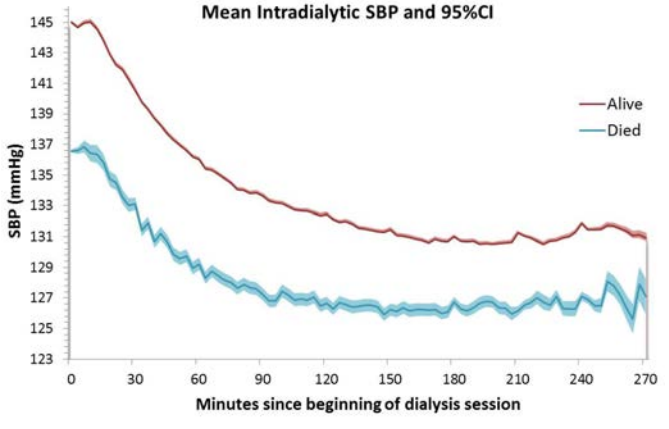
Intradialytic Dynamics of Systolic Blood Pressure in Hemodialysis Patients Based on Survival Status

John W. Larkin,[1] Dugan Maddux,[1] Yue Jiao,[1] Jeroen Kooman,[2] Frank van der Sande,[2] Hao Han,[1] Sophia Rosen,[1] Len A. Usvyat,[1] Peter Kotanko,[3,4] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America (FMCNA), Waltham, MA; [2]Maastricht Univ Medical Centre, Maastricht, Netherlands; [3]Renal Research Inst, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Low systolic blood pressure (SBP) before dialysis has been reported to be associated with worsened outcomes in hemodialysis (HD) patients (Maddux et al., ASN 2014). However, the dynamics of intradialytic SBP and patient outcomes have not been well characterized in this population. We aimed to understand the dynamics of SBP during dialysis in patients based on their survival status.

Methods: We studied HD patients treated at FMCNA facilities in 2014 with recorded intradialytic SBP data. The population mean intradialytic SBP was computed in 20 minute intervals during dialysis per patient per treatment; all treatments were then averaged per patient and thereafter for the entire cohort. Patient survival was recorded in 2014 (i.e. "alive" or "died").

Results: 31,053 and 2,835 patients (338,771 and 20,380 measurements respectively) were used for calculation of the mean SBP at each 20 minute time point in "alive" and "died" groups, respectively. The results show that the mean intradialytic SBP declines to a similar extent in both patients who died and survived, but patients that died exhibited a lower initial predialysis SBP and greater overall intradialytic variability.



Conclusions: These investigations of the dynamics of intradialytic SBP identify increased variability during dialysis and lower starting levels in patients who died. In both patients who were alive and died, SBP declines to a similar extent throughout dialysis. These findings suggest that lower predialysis SBP and intradialytic variability may be associated with mortality in the HD population.

Choosing the Right Analysis of Repeated Events for Clinical Trials in Dialysis

George Tomlinson,[1] Stephanie Dixon,[2] Amit X. Garg,[3] Charmaine E. Lok.[1] *[1]Medicine, Toronto General Hospital, Toronto, ON, Canada; [2]ICES-KDT; [3]London Health Sciences Centre.*

Background: Cardiovascular (CV) events are a leading cause of morbidity and mortality in hemodialysis (HD) patients. There is a paucity of randomized clinical trials (RCT) in nephrology and fewer positive ones, perhaps due to incorrect choice of endpoints or inadequate power. We simulated RCTs with repeated CV events and competing non-CV death to determine how different analytic methods affected study power (sample size).

Methods: We simulated 1000 RCTs of 1100 patients, with frequency and timing of CV events (CV death, MI, stroke, PVD, CV revascularization, and leg amputation) based on real observations in an Ontario HD administrative cohort (n=9647) from 2004-2011. In simulations, patients were randomized to placebo or a treatment with a known effect and censored at 4 years or non-CV death. We analyzed this data with 1) a Cox model for time to first event, 2) a model with non-CV death as a competing risk, 3) a negative binomial (NB) model and 4) several adaptations of the Cox model for repeated events (e.g., Wei, Lin and Weissfeld, WLW). To check for 2 potential problems (finding a difference when there was none and missing a true difference), we ran simulations in 2 scenarios: 1) with zero treatment effect, we calculated the false positive rate; 2) when the treatment delayed CV events by 33%, we calculated the true positive rate (power) based on the 1000 simulations.

Results: In the source (real) data, 45% of patients had ³2 CV events; the overall CV event rate was 0.26/yr. When there was no effect of treatment, the NB model had a false positive rate of 11%; for all other models, it was the expected 5%. For the time to first event, competing risk and the WLW marginal Cox model, power was similar (72%) and notably higher than for the remaining Cox-type models (52%-61%).

Conclusions: The WLW Cox model for repeated events was as powerful as models for time to first event but has the advantage of assessing the impact on all (repeated) events a patient experiences. This highlights the importance of choosing the appropriate analytic method when designing a clinical trial in HD patients to maximize the likelihood of both a positive and a meaningful result.

FR-PO744

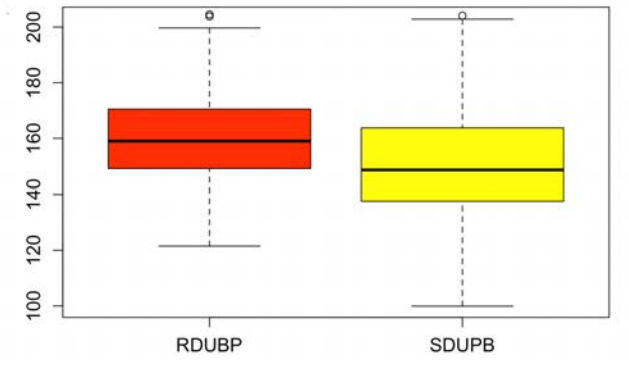
Routine Predialysis Measurements of Systolic Blood Pressure Are Higher Than Predialysis Standardized Measurements of Systolic Blood Pressure

Dana Miskulin,[1] Jennifer J. Gassman,[4] David W. Ploth,[5] Manisha Jhamb,[6] Lavinia A. Negrea,[7] Mahboob Rahman,[7] Ronald Schrader,[2] Susan Paine,[2] Philip Zager.[2,3] *[1]Tufts; [2]UNM; [3]DCI; [4]Cleveland Clinic; [5]MUSC; [6]Univ of Pittsburgh; [7]Case Western.*

Background: Measurement of blood pressure (BP) in the dialysis unit does not follow American Heart Association recommendations. We determined the differences between systolic BP (SBP) measured in routine practice versus a standardized procedure.

Methods: The Blood Pressure in Dialysis Study is a pilot, multicenter, randomized clinical trial that assesses treatment of hypertensive HD patients to two BP targets. Measurement of predialysis SBP is done after 5 minutes rest, 3 readings 1 minute apart, with attention to cuff size, placement and patient positioning. We compared the 2-week averaged routine predialysis SBP (RDUSBP) taken immediately prior to enrollment with the 2-week averaged predialysis standardized SBP (SDUSBP) in the first 2 weeks of baseline. The within subject variability in SBP, (s^2_W) was estimated by mixed linear regression.

Results: We studied 186 patients. The two week averaged RDUSBP was a mean (SD) 10.3 (16.6) mm Hg higher than 2 week averaged SDUSBP (p<0.001).



The RDUSBP was ± 5 mm Hg of the SDUSBP in 20% of patients, 6-15 mm Hg higher in 30%, 15-25 mm Hg higher in 17%, >25 mm Hg higher in 17% and >5 lower in 16%. Estimates of s^2_W for RDUSBP (15.7^2) and SDUSBP (19.6^2) were not significantly different, (p>0.99). Differences between RDUSBP and SDUSBP tended to be greatest among those with a high body mass index.

Conclusions: SDUSBP were, on average, 10 mm Hg lower than RDUSBP measured in the dialysis unit. Reliance on routine BP measurements may lead to over-treating hypertensive HD patients. More attention to the measurement of BP in dialysis unit is needed.

Comparison of Central and Peripheral Blood Pressure in Predicting Cardiovascular Surrogates in Patients with End-Stage Renal Disease

Kyoung Sook Park, Younkyung Kee, Shin-Wook Kang, Tae-Hyun Yoo. *Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Hypertension is an established cardiovascular (CV) risk factor and is closely related with mortality in end-stage renal disease (ESRD) patients. Recent studies have demonstrated that central blood pressure (cBP) is a significant predictor of CV disease in the general population, because cBP reflects the loading conditions of the coronary and cerebral arteries and vascular damage. Therefore, we investigated the association between cBP and CV surrogates compared with peripheral blood pressure (pBP) in patients with ESRD.

Methods: A cohort of 92 ESRD patients from the Cardiovascular and Metabolic Disease Etiology Research Center between November 2013 and February 2015 was selected. cBP was measured by SphygmoCor noninvasively. CV surrogates were determined by carotid intima-media thickness, pulse wave velocity (PWV) and left ventricular mass index (LVMI). Linear regression analysis and Steiger's Z test were used to compare predictive ability of cBP and pBP for CV surrogates.

Results: The mean age was 53.2 years and 52 (56.5%) were male. Mean systolic cBP (cSBP) and central pulse pressure (cPP) was 140.2±28.9 and 57.1±22.8 mmHg. Mean systolic pBP (pSBP) and peripheral pulse pressure (pPP) was 145±25.8 and 65.8±22.2 mmHg. There was an independent association of cSBP and pSBP with PWV (ß=0.408, P<0.01; ß=0.322, P=0.001) and LVMI (ß=0.370, P=0.001; ß=0.382, P<0.001). cPP and pPP also were independently associated with PWV (ß=0.381, P<0.001; ß=0.353, P=0.001) and LVMI (ß=0.411, P<0.001; ß=0.497, P<0.001) after adjustment for confounding factors. However, there were no significant differences in the predictive value of cSBP and pSBP for estimating PWV (adjusted R^2, 0.494 vs. 0.431, P=0.07) and LVMI (adj R^2, 0.215 vs. 0.220, P=0.885). No significant difference was found for cPP and pPP for predicting PWV (adj R^2, 0.451 vs. 0.429, P=0.546) and LVMI (adj R^2, 0.220 vs. 0.269, P=0.320).

Conclusions: Although cBP values were closely associated with CV surrogates, these values did not provide additional information beyond pBP in predicting CV risk in patients with ESRD.

FR-PO746

Early Mortality in Hemodialysis Patients Anticoagulated for Atrial Fibrillation

Stanislav S. Bushik,[1] N. Stanley Nahman,[1] Riad Elmor,[2] Jennifer L. Waller,[2] Robert A. Sorrentino,[1] William R. Maddox,[1] Mufaddal F. Kheda,[1] Matthew J. Diamond.[1] *[1]Medicine, Georgia Regents Univ, Augusta, GA; [2]Biostatistics & Epidemiology, Georgia Regents Univ, Augusta, GA.*

Background: Atrial fibrillation (AF) is prevalent in the Hemodialysis (HD) population and portends a high mortality rate. AF also causes embolic stroke and is treated with lifelong oral anticoagulation (OAT). We have previously shown early increased mortality in HD patients receiving OAT without significant stroke reduction (JASN, 25:609A, 2014). It is unclear why OAT increased early mortality in these patients. To address this question, we queried the USRDS for unique risk factors for mortality in this cohort.

Methods: All incident adult HD cases from the USRDS for 2005-2008 were queried for demographics, access type, risk factors before dialysis, and mortality. Data were derived from ICD9 and CPT codes, or Form 2728. Proportional hazards models were used to estimate the hazard ratio (HR) for death within 90 days.

Results: 34,522 incident HD patients with AF were identified, 6664 (19.3%) of whom died within 90 days of the initiation of dialysis. For the entire group, demographics showed: 83.1% Caucasian, mean age 75.4 years (SD=9.0), and 41.5% female. When controlling for diabetes, cardiomyopathy TIA, pulmonary hypertension, aortic stenosis, CHF, MI, coagulation defects, obesity, cardiac device, age and access type the HR for death in the OAT group was 1.10 (95% CI 1.04 - 1.16). The 1-, 2- and 3-month mortality rates were 6%, 15% and 22% in OAT and 5%, 12% and 19% in non-OAT, respectively. Major bleeding episodes were not significantly associated with mortality (p=0.59).

Conclusions: OAT therapy in HD patients with AF may contribute to the increased death rate observed during the first 90 days of dialysis, but not apparently due to bleeding. We speculate that OAT use may be associated with non-hemorrhagic complications that may lead to increased mortality in the HD population. Defining this level of clinical detail is beyond the scope of an administrative dataset like the USRDS. Future studies addressing non-hemorrhagic effects of OAT may provide new insights on possible causes of early mortality in these patients.

FR-PO747

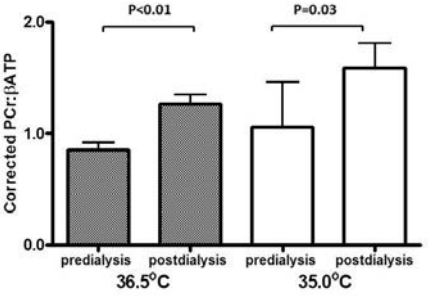
Reduced Temperature Hemodialysis Augments Dialysis Induced Improvement of Cardiac High Energy Phosphate Levels

Rajan Patel, Elaine Rutherford, Kathryn K. Stevens, Sandosh Padmanabhan, Alan G. Jardine, Patrick B. Mark. *Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom.*

Background: ^{31}Phosphorus magnetic resonance spectroscopy (^{31}P-MRS) measures levels of high enery phosphates, including phosphocreatinine:β ATP (PCr:β ATP) ratio which evaluates cardiac metabolic activity. PCr:β ATP is significantly reduced in end stage renal disease (ESRD) patients. Reducing hemodialysate temperature by 1-2°C improves intradialytic hypotension and cardiac function. The effects of reduced temperature dialysis on cardiac metabolism have not been evaluated. We compared myocardial function and PCr:βATP ratios levels before and after normothermic and reduced temperature dialysis.

Methods: Twelve hemodialysis patients underwent cardiac MRI and ^{31}P MRS of their left ventricle (LV) within 30 minutes before (pre) and after (post) three normothermic (36.5°C) and three reduced temperature (35.0°C) maintenance dialysis sessions. Left ventricular dimensions were measured by an observer blinded to intervention. PCr: β ATP were calculated from ^{31}P-MR spectra.

Results: Reduced temperature hemodialysis was significantly associated with increased predialysis LV ejection fraction (36.5°C:64.5%±6.6 vs. 35.0°C:69.0%±6.1;p=0.03). At both temperatures, hemodialysis was significantly associated with increased mean LV ejection fraction (36.5°C:pre 64.5%±6.6,post 70.9%±6.8, p=0.002;35.0°C :pre 69.0%±6.1, post 74.2%±8.3, p<0.01). PCr:βATP was significantly higher after normothermic (p<0.01) and reduced temperature hemodialysis (p=0.03:). Mean increase in PCr:βATP was higher after reduced temperature compared to normothermic hemodialysis (+51.5% vs +74.1% respectively).



Conclusions: Hemodialysis is associated with improved myocardial metabolic activity and this effect may be amplified by reducing the dialysate temperature even in patients with no intradialytic hypotension.

FR-PO748

Risk Grading by CHA2DS2_Vasc Score Is Useful in Non-Dialysis Subjects with Atrial Fibrillation while It Is Not Useful in Dialysis Patients Because of Their Very High CHA2DS2_Vasc Scores

Masaki Ohsawa.[1,2] *[1]Dept of Internal Medicine, Iwate Medical Univ, Morioka, Japan; [2]Dept of Internal Medicine, Morioka Tsunagi Onsen Hospital, Morioka, Japan; [3]Dept of Hygiene and Preventive Medicine, Iwate Medical Univ, Iwate Prefecture, Japan.*

Background: Whether CHA2DS2_Vasc score is useful for predicting the risk of outcomes has not been sufficiently examined in dialysis patients with AF.

Methods: Two prospective studies of 1,109 dialysis patients (AF group (n=35); non-AF group (n=1,074)) and 26,469 community dwellers (AF group (n=26,058); non-AF group (n=411)) living in the same area were conducted. Subjects were subdivided into four groups according to CHA2DS2_Vasc score (G1: CHA2DS2_Vasc score = 0~1; G2: score = 2; G3: score = 3; G4: score = 4+). Crude mortality rates of all-cause and cardiovascular death and crude incidence rates of stroke (per 1000 person-years) were estimated in each group.

Results: Results were shown in the table.

	AF (-)	AF (+)	CHADS2 Vasc 0-1	2	3	4+
community dwellers						
subjects (n)	26058	411	108	133	88	82
all-cause death (mortality rate)	993 (6.8)	57 (26.3)	11 (11.8)	17 (23.4)	12 (26.0)	17 (43.6)
cardiovascular death (mortality rate)	211 (1.5)	27 (12.5)	4 (6.8)	8 (11.0)	6 (13.0)	9 (23.1)
stroke (incidence rate)	692 (4.8)	57 (28.2)	9 (16.2)	18 (26.5)	13 (30.3)	17 (47.8)
dialysis patients						
AF (+) subjects (n)		35	6	1	6	22
all-cause death (mortality rate)		26 (278.9)	2 (81.4)	1 (404.9)	3 (158.1)	20 (423.7)
cardiovascular death (mortality rate)		9 (96.6)	0 (0)	0 (0)	1 (52.7)	8 (169.5)
stroke (incidence rate)		5 (59.7)	0 (0)	0 (0)	0 (0)	5 (132.4)
AF (-) subjects (n)	1074		218	331	242	283
all-cause death (mortality rate)	384 (88.7)		26 (25.9)	83 (58.3)	100 (106.4)	175 (181.8)
cardiovascular death	187 (43.2)		14 (13.9)	41 (28.8)	55 (58.5)	77 (80.0)
stroke (incidence rate)	192 (49.7)		21 (21.5)	49 (37.4)	48 (59.4)	74 (96.4)
Mortality/incidence rates are expressed as per 1000 person-years.						

Conclusions: CHA2DS2_Vasc score is useful for predicting the risk of outcomes in non-daialysis subjects with AF and dialysis subjects without AF. Dialysis patients with AF already had very high scores and the risk grading by CHAD2DS2_Vasc score is not useful.

FR-PO749

Post Stroke In-Hospital Disability Deterioration and Mortality of Community-Onset Stroke in Patients with and without End-Stage Renal Disease

Tomoko Usui,[1] Norio Hanafusa,[1] Hideo Yasunaga,[2] Masaomi Nangaku.[1]
[1]Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Japan; [2]Dept of Clinical Epidemiology and Health Economics, School of Public Health, the Univ of Tokyo, Japan.

Background: Increasing evidence suggests that end-stage renal disease is associated with higher risk and severity of cerebrovascular disease. However, the risk factors for post stroke disability and mortality is not clear. We examined the association between risk factors including dialysis treatment and disability deterioration and mortality during hospital stay of community-onset stroke.

Methods: The Japanese Diagnosis Procedure Combination database includes administrative claims and discharge abstract data of about 50% of all acute-care inpatients in Japan. Using this database, we extracted data of inpatients age ³20 years old, admitted within 3 days after community-onset stroke between July 2010 and March 2013. Disability level was divided into modified Rankin Scale (mRS) 0-1, 2-3, 4-5, and 6 (death). Disability deterioration was defined as an increase in disability level. The odds ratio (OR) for in-hospital disability deterioration and mortality was calculated using a logistic regression model.

Results: Out of 438,569 patients, 7,633 (1.7%) had dialysis therapy. The median length of stay was 21 and 20 days for patients with and without dialysis, respectively. During the hospital stay, there were 101,024 (23.0%) disability deterioration and 46,029 (10.5%) death. The patients with dialysis had higher rate of disability deterioration (26.7%) and mortality (13.0%) compared to those without. After adjustment with age, gender, BMI, mRS, Activities of Daily Living, smoking habits, hypertension, diabetes, dyslipidemia, atrial fibrillation, coronary heart disease, heart failure, peripheral arterial disease, cerebrovascular complications, antiplatelet, anticoagulant, and thrombolytic medications, multivariate-adjusted ORs of dialysis for deterioration of disability was 1.57 (95%CI 1.48-1.66), and in-hospital mortality was 1.72 (95%CI 1.59-1.86).

Conclusions: Dialysis treatment was an independent risk factor for in-hospital disability deterioration and mortality of community-onset stroke.

FR-PO750

Proportion of Treatments with Low Systolic Blood Pressure and Short Term Mortality in Incident Hemodialysis Patients

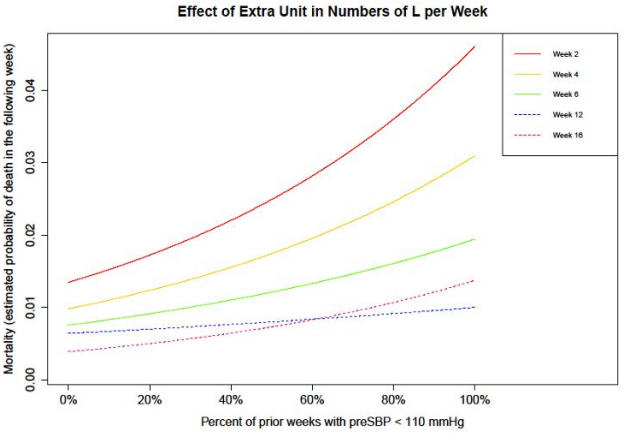
Dugan Maddux,[1] John W. Larkin,[1] Danqing Xu,[2] Len A. Usvyat,[1] Frank van der Sande,[3] Jeroen Kooman,[3] Peter Kotanko,[4] Franklin W. Maddux.[1] *[1]Medical Office, Fresenius Medical Care North America, Waltham, MA; [2]Univ of California at Santa Barbara, Santa Barbara, CA; [3]Maastricht Univ Medical Centre, Maastricht, Limburg, Netherlands; [4]Renal Research Inst, New York, NY.*

Background: Prior studies have associated low mean predialysis systolic blood pressures (preSBP) with increased 120 day risk for mortality in incident hemodialysis (iHD) patients (Maddux et al., ASN 2014). This study aimed to investigate how the percent (%) of low mean preSBP during the prior weeks' hemodialysis (HD) treatments affects the short term risk of mortality in iHD patients.

Methods: For this study, 50,525 iHD patients at Fresenius Medical Care North America (FMCNA) clinics were investigated from 1/1/2004 to 12/31/2010. From the first date of outpatient chronic dialysis (FDD), the % of the prior weeks' mean preSBP <110 mmHg was calculated for the first 4 months of HD. Mortality risk in the following week (7 days) was analyzed by the % of the prior week's mean preSBP <110 mmHg at weeks 2, 4, 6, 12, and 16 from FDD.

Results: We observed that the short term risk for mortality in the following week increases in iHD patients as the % of the prior week's mean preSBP <110 mmHg increases at weeks 2, 4, and 6 from the FDD; the risk for mortality was found to be the greatest at week 2 and was slightly reduced by week 6. Conversely, by week 12 and 16 from the FDD, the % of the prior week's mean preSBP <110 mmHg was not found to be related with the risk of mortality in the next week.

Figure 1: iHD Patient 7 Day Risk of Mortality by the % of the Prior Week's Low preSBP



Conclusions: This study demonstrates that increases in the % of low mean preSBP during the prior weeks' hemodialysis (HD) treatments is associated with heightened short term risks of mortality during the first 6 weeks of iHD, but not during weeks 12 and 16 from the FDD.

FR-PO751

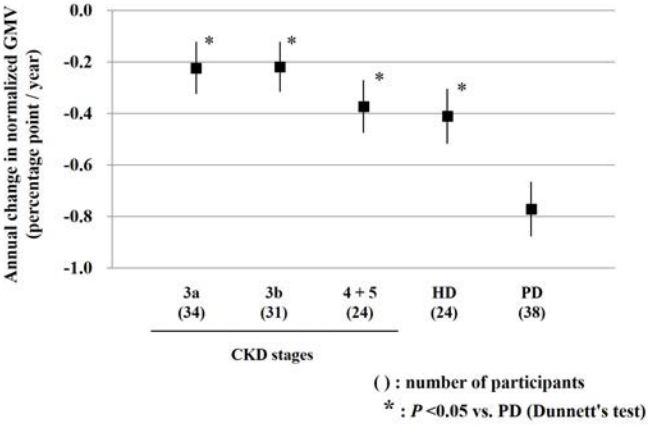
The Possibility of Faster Progression of Brain Atrophy in Patients on Peritoneal Dialysis Compared with Hemodialysis

Kazuhiko Tsuruya,[1] Hisako Yoshida,[1] Takanari Kitazono.[2] *[1]Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; [2]Dept of Medicine and Clinical Sciences, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.*

Background: Brain atrophy has been reported in chronic kidney disease (CKD) patients, especially in hemodialysis (HD) patients. Recently, we reported faster decline in normalized gray matter volume (GMV) in peritoneal dialysis (PD) patients compared with non-dialysis-dependent CKD (ND) (Tsuruya, et al. Am J Kidney Dis, 2015). However, it has not been reported on the comparison of the progression rate of brain atrophy between PD and HD patients. In the present study, we compared it among PD, HD, and ND patients.

Methods: A total of 151 patients of 38 PD patients aged 60 ± 12 years (men 23, diabetes 11), 24 HD patients aged 64 ± 6 years (men 18, diabetes 9), and 89 ND patients (CKD stage 3a, 34; stage 3b, 31; stages 4-5, 24) patients aged 62 ± 11 years (men 46, diabetes 25, eGFR 38.9 ± 11.6 mL/min/1.73m^2) were recruited and underwent MRI scanning at baseline and after two years. T1-weighted MRI images were analyzed with statistical parametric mapping software. Total gray matter, total white matter, and cerebrospinal fluid were segmented and each volume was quantified. Normalized GMV was calculated as percentage of intracranial volume to normalize for head size variability. We compared the annual change in normalized GMV among CKD stages.

Results: Annual change in normalized GMV was significantly higher in PD patients than other CKD patients. This finding remained significant even after adjustment for potential confounding factors.



Conclusions: Progression of brain atrophy is significantly higher in PD patients than other CKD patients including HD patients, independent of age, gender, diabetes, and blood pressure level.

FR-PO752

In Centre Nocturnal Haemodialysis: Improving Outcomes and Experience for Patients Matthew P.M. Graham-Brown,[1,2] Darren Robert Churchward,[1,2] Alice C. Smith,[1,2] Richard J. Baines,[1,2] James O. Burton.[1,2] *[1]John Walls Renal Unit, Univ Hospitals of Leicester, Leicester, United Kingdom; [2]Dept of Infection, Immunity and Inflammation, Univ of Leicester, Leicester, United Kingdom.*

Background: Extended periods of haemodialysis (HD) improve patient outcomes. Home HD schedules can deliver extended dialysis, but there are patient and physician related barriers that make home therapies impossible for many. We explored in centre nocturnal HD (INHD) as a method of offering extended periods of HD to patients unsuitable for home therapy.

Methods: Ten prevalent HD patients switched from standard HD (3x4 hours) to INHD (3x>5 hours) for four months. Mean ultrafiltration (UF) volumes (L), relative UF rates (ml/kg/hour) and absolute UF rates (ml/hour) were calculated. Additional, biochemical and haematological data, data on dialysis adequacy and blood pressure control were collected. Changes in quality of life (QoL) were assessed using SF12, EQ-5D and the Hospital Anxiety and Depression Score (HADS) questionnaires.

Results: Seven patients completed four months of INHD. Mean dialysis time per session was 355 minutes (SD±43.92). Mean total UF volume increased from 2.0±5.1L to 2.6±3.4L (p=0.02), but there was a reduction in absolute mean UF rates from 513±121ml/hour on standard dialysis, to 356±66 ml/hour on INHD (p=0.03) and a decrease in mean relative UF rates from 6.5±1.7ml/kg/hr to 4.6±1.6ml/kg/hr (p=0.03). Adequacy measured by urea reduction ratio improved from 72±2% to 80±3% (p<0.001), with a trend towards improved phosphate control to within therapeutic targets; from1.7±0.6mmol/L to 1.2±0.2mmol/L (p=0.08). In addition, there were improvements in all QoL scores. Mean EQ-5D visual analogue score improved from 48±16.9 to 72±13.2 (p=0.003). Mean HADS anxiety score decreased from 9±5.83 to 3.57±3.04 (p=0.03). SF12 physical component score improved from 31.31±3.32 to 41.69±10.19 (p=0.05).

Conclusions: Despite an increase in total UF volume, extended INHD led to an overall reduction in UF rate that has been shown to abrogate HD induced cardiac injury. Other physiological benefits included improved urea clearance and better phosphate control. There were also significant improvements in patient QoL measures over four months.

FR-PO753

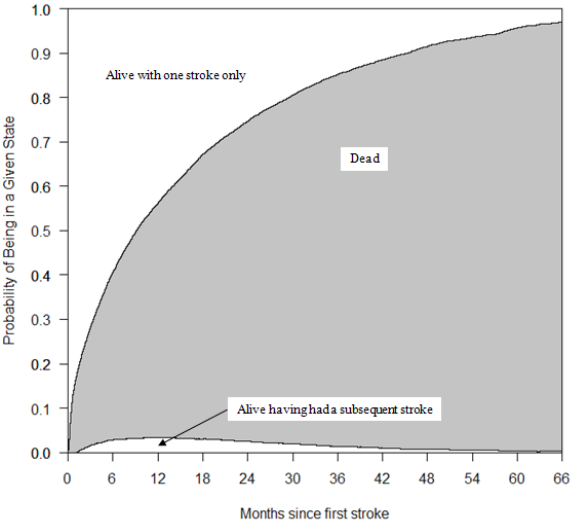
Association of Multiple Strokes on Mortality in Incident Hemodialysis Patients: An Application of Multistate Model to Determine Transition Probabilities James B. Wetmore,[1] Jonathan D. Mahnken,[2] Milind A. Phadnis.[2] *[1]Medicine, Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; [2]Biostatistics, Univ of Kansas Medical Center, Kansas City, KS.*

Background: Little is known about the effect of multiple, or subsequent, ischemic strokes in patients receiving dialysis.

Methods: A retrospective cohort study of incident hemodialysis patients with Medicare Parts A and B coverage who had experienced a first ischemic stroke was performed. A multistate model with Cox proportional hazards was used to predict transition probabilities from first ischemic stroke to subsequent stroke or to death. Demographic and clinical factors associated with the respective transition probabilities were determined.

Results: Overall, 12,054 individuals (mean age 69.7 years, 41.3% male, 53.0% Caucasian and 34.0% African-American) experienced a first stroke. Female sex was associated with an increased risk of having a subsequent stroke (adjusted hazard ratio1.37, 95% confidence intervals 1.20 – 1.56, P < 0.0001); African-Americans, as compared to Caucasians, had lower likelihood of dying after a first stroke (0.81, 0.77 – 0.85, P < 0.0001). A subsequent stroke trended towards having a higher likelihood of transitioning to death compared to a first new stroke on dialysis (1.72, 0.96 – 3.09, P = 0.071). The probability of transitioning to a subsequent stroke increased over the first 6 months, peaked at approximately 12 months, then declined steadily over time (Figure). When a subsequent stroke occurs at 24 months, probability of survival dropped >15%, in absolute terms, from 0.254 to 0.096, with substantial drops observed at subsequent time points such that the probability of survival was more than halved.

Conclusions: Likelihood of subsequent ischemic stroke and of survival in dialysis patients appears to vary by sex and race.



Transition probabilities (Pr) at different time points after first new stroke

Time in Months	Transitioning from first stroke to subsequent stroke	Transitioning from first stroke to death	Remaining alive with a with a first stroke only
t = 3	Pr = 0.015	Pr = 0.268	Pr = 0.717
t = 6	Pr = 0.028	Pr = 0.379	Pr = 0.593
t = 12	Pr = 0.033	Pr = 0.529	Pr = 0.438
t = 24	Pr = 0.025	Pr = 0.721	Pr = 0.254
t = 36	Pr = 0.014	Pr = 0.838	Pr = 0.148
t = 48	Pr = 0.007	Pr = 0.908	Pr = 0.085

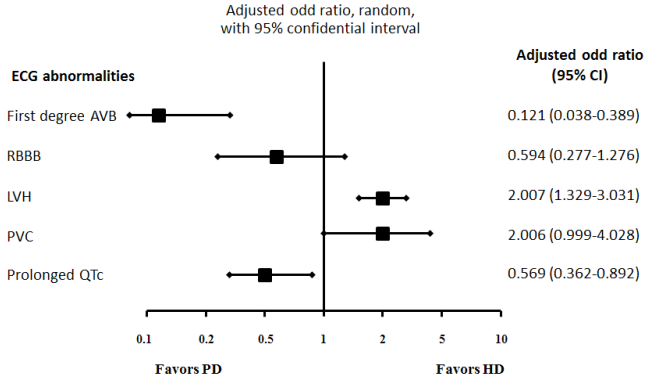
Electrocardiographic Manifestation in End-Stage Renal Disease Patients with Different Renal Replacement Treatment Thasinas Dissayabutra,[1] Eiji Kusano.[2] *[1]Biochemistry, Chulalongkorn Univ, Pathumwan, Bangkok, Thailand; [2]Internal Medicine, Div of Nephrology, Jichi Medical Univ, Shimotsuke, Tochigi, Japan.*

Background: End-stage renal disease commonly coexists with certain type of cardiovascular diseases, partially reflects the burden of cardiac in uremic state and dialysis methods. Hemodynamic changes are different between predialysis state, hemodialysis (HD), peritoneal dialysis (PD) and post-kidney transplant (Post-KT) patients. This study aimed to investigate the cardiac disorders using electrocardiographic (ECG) features between each stage of CKD patients, including HD, PD and Post-KT.

Methods: ECG records were analyzed retrospectively in 974 participants, including (a) 48 Early CKD (CKD stage 1-2), (b) 188 Advanced CKD (CKD stage 3, 4 and 5), (c) 567 Hemodialysis (HD), (d) 112 chronic ambulatory peritoneal dialysis (PD) and (d) 59 post-kidney transplant (KT) patients. ECGs were analyzed by two examiners for major ECG abnormalities.

Results: A few ECG abnormalities were observed in Early CKD, but highly frequent QTc prolongation and first degree atrio-ventricular block (AVB) were detected in Advanced CKD. PD patients developed more left ventricular hypertrophy (LVH) and premature ventricular contraction than HD counterparts.



Four-consecutive-year annual ECGs showed the significant increase of AVB, LVH and QTc prolongation in HD patients. QTc prolongation recovery was observed in KT with the fewer LVH prevalence. We found that the age was a dependent factor for AVB and RBBB development, and the remaining GFR correlated with the prevalence of AVB and QTc prolongation in CKD patients.

Conclusions: Prolonged QTc, first-degree AVB, LVH and PVC were prevalent in ESRD and depended on renal replacement therapy method. The physicians should be cautious and promptly treat to the fatal arrhythmias.

The Relation Between Sclerostin, Peripheral Vascular Calcification, and Cardiovascular Events in ESRD Patients Young Ju Na, Sung Yoon Lim, Myung-gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Nephrology, Korea Univ Hospital, Seoul.*

Background: Sclerostin, a negative regulator of Wnt signaling pathway produced by osteocyte, is a potent regulator of bone metabolism and a novel candidate for the bone vascular axis in chronic kidney disease patients. Although sclerostin is known as an inhibitor of vascular calcification, recent studies demonstrated conflicting results about the association between sclerostin and cardiovascular events or mortality. In this study we tested the association between sclerostin, peripheral vascular calcification, and cardiovascular events in end stage renal disease (ESRD) patient starting peritoneal dialysis.

Methods: In this prospective study, we included 45 ESRD patients admitted to Korea University Anam Hospital for starting peritoneal dialysis. Circulating sclerostin level was measured in all patients before the start of peritoneal dialysis. Simple vascular calcification score (SVCS) was measured using plain radiographic films of both hands and the pelvis. Median follow up period was 36 months.

Results: Higher sclerostin level was associated with male sex, diabetes mellitus, higher left ventricle (LV) mass index, and lower LV fractional shortening in univariate analysis. ESRD patients with severe vascular calcification (SVCS ³3) had significantly higher prevalence of diabetes mellitus. They had higher pulse wave velocity, alkaline phosphatase, and lower cholesterol levels, LV fractional shortening and in multivariate analysis, the presence of diabetes mellitus (OR, 44.59, p=0.023), lower cholesterol levels (OR, 0.94, p=0.032) were independent risk factors predicting severe vascular calcifications. In multivariate Cox regression model, higher pulse wave velocity (HR 1.03, p=0.028) was significant predictor for cardiovascular events. In addition higher sclerostin group (HR 9.82, p=0.094) and lower albumin levels (HR 0.23, p=0.081) display a strong tendency of increased cardiovascular events.

Conclusions: This study showed the possible important role of sclerostin in the development of vascular calcification and cardiovascular events in PD patients. Longer term follow up with larger sample size will be needed to clarify this issue.

FR-PO756

Use of Anticoagulants in Patients with Atrial Fibrillation and End Stage Renal Disease: A Study of Real World Data Lloyd P. Haskell,[1] Chris Knoll,[2] Patrick Ryan,[3] Zhong Yuan.[3] *[1]Cardiovascular, Janssen R and D, Raritan, NJ; [2]Epidemiology, Janssen R and D, Raritan, NJ; [3]Epidemiology, Janssen R and D, TItusville, NJ.*

Background: End stage renal disease (ESRD) in patients with atrial fibrillation (AF) is a significant cause of morbidity and mortality.While these patients are at high risk for stroke, there are limited data with respect to use of anticoagulants in clinical practice and current guidelines are not clear on how to manage them.

Methods: US-based, four large healthcare databases (Truven MarketScan Commercial Claims/Encounters [CCAE], Medicare Supplemental [MDCR], Medicaid [MDCD]) and Optum Clinformatics [Optum]) were used to establish cohorts of patients with AF and ESRD, who were identified using ICD-9 codes. The first encounter with evidence of both conditions during the inception period of 2010-2012 was the index date; patients must have had at least 1 year enrolment prior to and after the index date to be eligible for the study. The use of anticoagulants was examined during the follow-up period.

Results: Table 1 shows patient demographics and use of anticoagulants by data source. As expected, the privately-insured patient populations (CCAE and Optum) as well as the Medicaid population [MDCD] were younger as compared with the Medicare eligible population (MDCR). Across study cohorts, approximately 37% to 40% of patients with AF and ESRD received at least one dispensing of warfarin, with the exception of the Medicaid population (14%). About 3% to 4% of patients (except for Medicaid) received at least one dispensing of novel oral anticoagulant therapy (rivaroxaban, apixaban, or dabigatran).

Table 1. Use of Anticoagulants in Patients with AF and ESRD

Datasource	N	Mean Age [S.D.]	Male, %	Novel Oral Anticoagulants	Warfarin
Commercial	3650	56 [7.7]	66.2%	2.5%	37.7%
Medicare	9866	77 [7.7]	59.7%	3.4%	40.1%
Medicaid	5663	64 [3.7]	41.6%	0.6%	14.0%
Optum	2825	65 [12.4]	66.8%	4.1%	37.5%

Conclusions: Less than 40% of patients with AF and ESRD received anticoagulant therapy. As these are high risk patients, anticoagulant therapy may be underutilized. Further research is necessary to investigate clinical outcomes associated with anticoagulation in these patients.

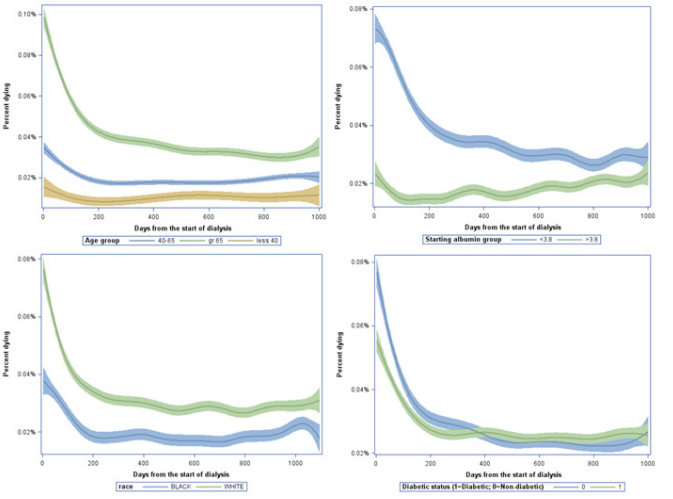
FR-PO757

Factors Determining Changes in Mortality Rates in Incident Hemodialysis Patients Jochen G. Raimann,[1] Len A. Usvyat,[2] Dugan Maddux,[2] Jeroen Kooman,[3] Frank van der Sande,[3] Kevin Chan,[2] Franklin W. Maddux,[2] Peter Kotanko.[1,4] *[1]Renal Research Inst; [2]Fresenius Medical Care North America; [3]Maastricht Univ Medical Centre; [4]Icahn School of Medicine at Mount Sinai.*

Background: The higher risk of death for incident hemodialysis (HD) patients decreases during the first year (Chan, 2011). Next to vintage, risk is also affected by patient characteristics, and the evolution of clinical and laboratory parameters. We analyzed how mortality rates change in different age groups, levels of albumin, in black and white, and in diabetic and non-diabetic patients after HD initiation.

Methods: We analyzed patients commencing HD in Fresenius Medical Care North America clinics between 1/1/2005 and 11/30/2014. We calculated proportions of patients dying from all causes in diurnal intervals starting with the first day on HD up to 1000 days. Only patients who had their first outpatient treatment on day 1 of their first ever HD were analyzed. We analyzed differences in mortality in the following strata: a) age groups (<40, between 40 and 65, and >65 years); b) serum albumin greater and below 3.8 g/dL; c) black and white; and d) diabetic and non-diabetic patients. We fitted penalized B-splines with 95% CIs through all available daily rates.

Results: We studied 334,880 patients. For all groups, mortality rates dropped within the first year. There were differences between groups of age, albumin and between black and white patients, but none between diabetic and non-diabetic patients.



Conclusions: Mortality rates decrease substantially once patients initiate HD. After approximately one year on HD, mortality remains consistent in all groups, but remains lower for those with higher albumin, younger age and black race. Diabetes appears to not affect mortality. Since only patients starting in an outpatient setting were included, selection bias may apply differently to the patient groups.

FR-PO758

Strong Association of Geriatric Nutritional Risk Index with the Infection-Related Mortality in Hemodialysis Patients: The Q-Cohort Study Yuta Matsukuma,[1] Shigeru Tanaka,[1] Masatomo Taniguchi,[1] Toshiaki Nakano,[1] Kosuke Masutani,[1] Hideki N. Hirakata,[2] Kazuhiko Tsuruya,[1,3] Takanari Kitazono.[1] *[1]Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; [3]Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan.*

Background: Geriatric Nutritional Risk Index (GNRI) is a simple but useful predictive marker for all–cause and cardiovascular mortality inhemodialysis(HD) patients. However, it is unclear whether the GNRI could predict the infection–related mortality in HD patients. We herein investigated the association between GNRI and the infection–related mortality in Japanese HD patients.

Methods: A total of 3,452 Japanese HD patients aged >18 years were prospectively followed for 4 years. Patients were divided into three groups by tertile of GNRI: Tertile1 (T1): <92.67; T2: 92.67–98.63; T3: >98.63. We estimated the relationship between GNRI and the all–cause mortality and infection–related mortality using a Cox proportional hazards model. To assess the additional predictive value of GNRI in risk assessment, we compared the c–statistics between serum albumin and GNRI.

Results: During the follow–up period, 566 patients died totally, and 121 patients died of infection–related mortality. All–cause mortality and infection–related mortality increased linearly with lower GNRI levels. After adjusting for confounding risk factors, the GNRI was an independent predictor of not only all–cause but also infection–related mortality (hazard ratio 6.51, 95% confidence interval 3.16–13.4 , p <0.001 for T1 vs. T3, and hazard ratio 3.04, 95% confidence interval 1.44–6.43, p = 0.004 for T2 vs. T3). When

GNRI was incorporated into a model with potential risk factors instead of serum albumin, the c–statistics increased significantly both in all–cause mortality (0.783 vs. 0.787, p = 0.021) and in infection–related mortality (0.802 vs. 0.812, p = 0.011).

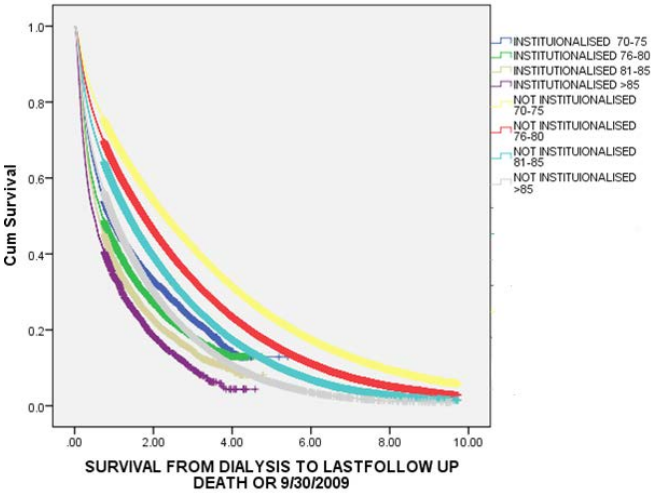
Conclusions: A lower GNRI is strongly associated with infection–related mortality in HD patients, and Our finding suggest that the predictive value of GNRI is superior to serum albumin.

FR-PO759

Survival in Elderly on Dialysis and Impact of Institutionalization Amarpali Brar, David Kau, Moro O. Salifu, Mary C. Mallappallil. *Renal, SUNY Downstate, Brooklyn, NY.*

Background: We hypothesized that in the very elderly dialysis patients in the United States, institutionalization in nursing homes would increase mortality in addition to age alone.

Methods: Data was obtained from the U.S. Renal Data System. Incident dialysis patients from 2001 to 2008 above the age of 70 were included. Follow-up period was from incident dialysis date to either death or last follow up on September 30, 2009. Patients above 70 were categorized into four groups according to age as 70-75 years, 76-80 years, 81-85 years, greater than 85 years and further divided into institutionalized and non-institutionalized.



Results: A total of 349,440 patients were identified above the age of 70 years at the time of initiation of dialysis. Major causes of end stage renal disease were diabetes, hypertension, glomerulonephritis, cystic kidney disease, and urological causes. Mean survival for non instutionalised patients was 3.15 ± 0.01 years for those between 70-75 years of age, 2.55±0.01 years for 76-80 years of age, 2.12±0.01 years for 81-85 years of age and 1.64± 0.01 years for those above 85 years at the time of initiation of dialysis respectively. For institutionalized patients, mean survival was significantly lower, 1.71±0.03 years for 70-75 years old, 1.44± 0.02 years for 75-80 years old , 1.25±0.02 years for 81-85 years old and more than 85 years and 1.04 ±0.02 for > 85 years age group, p=0.0001.The oldest group in non-institutionalized over the age of 85 years had a similar survival as the institutionalized ESRD patients 70-75 years of age.

Conclusions: There was increased mortality in institutionalized elderly patients as compared to non instutionalised elderly patients in the same age group. Keeping with the increased frailty and decreased benefits of therapies in the very elderly especially in those with additional co-morbidities besides age, palliative and end of life care should be considered.

FR-PO760

Geriatric Nutritional Risk Index Is a Simple Predictor of Mortality in Chronic Hemodialysis Patients Kosaku Nitta, Ken Tsuchiya. *Dept of Medicine, Kidney Center, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

Background: Malnutrition is common in hemodialysis (HD) patients, and it is associated with increasing risk of mortality. The geriatric nutritional risk index (GNRI) has been developed as a tool to assess the nutritional risk. The aim of the present study was to examine the reliability of the GNRI as a mortality predictor in a Japanese HD cohort.

Methods: We prospectively examined the GNRI of 332 maintenance HD patients aged 65.4 ± 13.2 years, 213 males, and followed up on them for 36 months. The patients were divided into quartiles (Q) according to GNRI values (Q1: <91.6, Q2: 91.7-97.0, Q3: 97.1-102.2, Q4: >102.3). Predictors for all-cause mortality were examined using Kaplan–Meier and Cox proportional-hazards analyses.

Results: The GNRI presented a normal distribution. During the follow-up period of 36 months, a total of 76 patients died. The overall mortality at the end of the 3-year observational period was 22.3 %. At the 3-year follow-up period, Kaplan-Meier survival rates for all-cause mortality were 72.3%, 79.3%, 84.9%, and 92.6% in Q1, Q2, Q3, and Q4, respectively (p = 0.0067). Multivariate Cox proportional-hazards analysis demonstrated that the GNRI was a significant predictor of adjusted all-cause mortality (HR 0.958; CI 0.929–0., p < 0.001).

Conclusions: The results of the present study demonstrate that the GNRI is a strong predictor of overall mortality in HD patients. However, cardiovascular mortality was not associated with GNRI values, and did not differ among the GNRI quartiles. The GNRI score can be considered a simple and reliable marker of predictor for mortality risk in Japanese HD patients.

FR-PO761

Frailty and Clinical Outcomes in Chronic Dialysis Patients Dong Ho Yang,[1] Eun jung Ko,[1] Hye yun Jeong.[1] *[1]Internal Medicine, CHA Bundang Medical Center, Seongnam, Republic of Korea; [2]Internal Medicine, CHA Gumi Medical Center, Gumi, Republic of Korea.*

Background: Frailty is a biological syndrome of decreased reserve and resistance to stressors and is independently associated with mortality and hospitalization in the general population. We investigated the relationship between frailty and clinical outcomes in chronic dialysis patients.

Methods: In this prospective study, 1,658 patients receiving chronic dialysis were enrolled. Chronic dialysis was defined as dialysis for more than 6 months. Of the 1,658 patients, 1,255 received hemodialysis. The remainder received peritoneal dialysis. Fried's criteria for frailty as modified by Woods et al. was used. A trained interviewer asked study participants about 5 frailty phenotypes (slowness, weakness, exhaustion, shrinking, and physical inactivity) using the RAND 36-item Short Form.

Results: The mean age was 55.2±11.9, and 55.2% were male. Overall, 577 (34.8 %) patients met the study definition of frailty. Another 757 (45.7%) patients were pre-frail. Table 1 shows the prevalence of frailty and its components by age group. During the 30-month follow-up period, 607 patients (79 non-frail, 249 pre-frail, and 279 frail) were hospitalized; and 87 patients (10 non-frail, 24 pre-frail, and 53 frail) died (P<0.001). Frailty was strongly associated with hospitalization (adjusted hazard ratio [HR] 1.80; 95% CI 1.4 to 2.3) and mortality (HR 2.37, 95% CI 1.11 to 5.02) in multivariate analysis. The relationship between frailty and hospitalization was strongest among patients age 40 to 49, with a HR of 3.02 (95% CI 1.48 to 6.20).

Table 1. The prevalence of frailty and its components by age.

	Age group (years)					P value
	< 40	40-49	50-59	60-69	≥ 70	
Frail, %	21.1	20.6	32.8	38.0	63.8	<0.001
Pre-frail, %	57.8	55.9	47.2	41.0	26.5	<0.001
Slowness/Weakness, %	33.0	40.9	35.2	34.6	30.6	0.130
Exhaustion, %	60.8	59.7	65.3	66.2	80.2	0.001
Inactivity, %	58.3	45.6	42.8	35.6	50.6	0.013
Shrinking, %	13.7	7.6	9.8	10.6	10.1	0.777

Conclusions: We found a high prevalence of frailty in chronic dialysis patients across all age groups. The risk of hospitalization and mortality in the 30-month follow-up period significantly increased in frail chronic dialysis patients.

FR-PO762

Outcomes of Early Initiation of Dialysis in Elderly Patients with End-Stage Renal Disease: A Propensity-Matched Analysis of a Prospective Cohort Study Jae Yoon Park,[1] Kyung Don Yoo,[1] Jeonghwan Lee,[2] Dong Ki Kim,[1] Kwon Wook Joo,[1] Shin-Wook Kang,[3] Chul Woo Yang,[4] Yong-Lim Kim,[5] Chun Soo Lim,[1] Yon Su Kim,[1] Jung Pyo Lee.[1] *[1]Seoul National Univ College of Medicine, Seoul, Korea; [2]Hallym Univ Hangang Sacred Heart Hospital, Seoul, Korea; [3]Yonsei Univ College of Medicine, Seoul, Korea; [4]The Catholic Univ of Korea College of Medicine, Seoul, Korea; [5]Kyungpook National Univ School of Medicine, Daegu, Korea.*

Background: The optimal timing for initiating dialysis in end-stage renal disease (ESRD) remains controversial, especially in elderly patients. We therefore investigated the effect of dialysis initiation timing on clinical outcomes in elderly patients with ESRD.

Methods: A total of 665 patients aged equal or over 65 years who started dialysis from August 2008 to February 2015 were enrolled in Clinical Research Center for End Stage Renal Disease cohort study in Korea. They were divided into 2 groups based on the median estimated glomerular filtration rate, which was 8.85 mL/min/1.73m^2. The primary outcome was patient survival and the secondary outcomes were cardiovascular events and Kidney Disease Quality of Life Short Form 36 (KDQOL-36) score.

Results: Overall cumulative survival rates were lower in early initiation group (Log-rank *P*<0.001). However, the survival rates showed no significant difference after matching propensity score. Additionally, early initiation of dialysis was not associated with survival rates after adjustment for age, sex, Charlson comorbidity index, hemoglobin, serum albumin, serum calcium and phosphorus level. Although the early initiation group showed lower physical component summary in KDQOL-36 at 3 months after dialysis, the difference of the scores was not significant at 12 months after dialysis.

Conclusions: Early initiation of dialysis was not associated with prognosis in elderly patients with ESRD. The physical functioning was worse for 3 months after dialysis but it became similar to late initiation of dialysis at 1 year after dialysis.

FR-PO763

1- and 2-Year Mortality Prediction Models for Patients Starting Chronic Dialysis Mikko Haapio,[1] Jaakko Helve,[1] Carola Gronhagen-Riska,[1,2] Patrik Finne.[1,2] *[1]Nephrology, Univ of Helsinki and Helsinki Univ Hospital, Helsinki, Finland; [2]Finnish Registry for Kidney Diseases, Helsinki, Finland.*

Background: Mortality risk of patients with end-stage renal disease (ESRD) is highly elevated compared to patients without ESRD. Taking into account our limited nephrological care resources and the simultaneously increasing number of ESRD patients there is a great need for means of mortality risk estimation to assist both in individualized patient care as well as in sound use of resources. Some mortality prediction models already exist, but many have shown a lack of comprehensiveness in data or in patient recruitment in their development.

Methods: Our objective was to design a prediction model for 1- and 2-year all-cause mortality in patients starting chronic renal replacement therapy. In addition, we aimed to build an easy-to-apply model consisting of only a few variables. We used the comprehensive data of the Finnish Registry for Kidney Diseases with complete coverage of Finnish ESRD patients. Model training group included all incident adult patients who started chronic dialysis in Finland from 1 January 2000 to 31 December 2008 (n=4335). The external validation cohort consisted of all those who started dialysis from 1 January 2009 to 31 December 2012 (n=1768). Prediction algorithms for 1- and 2-year mortality were developed using multivariate logistic regression with stepwise selection of variables. Our primary analyses included 32 variables, from which the most important ones were selected.

Results: Both final prognostic models, including only 6-7 variables, showed adequate discrimination (c-statistic 0.77 and 0.74 for 1- and 2-year mortality, respectively). Because of a significantly lower mortality in the newer (validation) cohort, both models somewhat overestimated mortality risk.

Conclusions: Mortality prediction algorithms could be more widely implemented into clinical treatment-planning of ESRD patients. Our prediction models perform sufficiently and are convenient to use, and could assist in individualized risk-stratification and, furthermore, in equal and fair sharing of limited health care resources.

FR-PO764

Comorbidity Burden at Dialysis Initiation and Mortality: A Retrospective Cohort Study Alwyn Titus Gomez,[1] Bryce A. Kiberd,[1] Talal A. Alfaadhel,[2] Brenda Hemmelgarn,[3] Karthik K. Tennankore.[1] *[1]Medicine, Dalhousie Univ, Halifax, NS, Canada; [2]Medicine, Univ of Toronto, Toronto, ON, Canada; [3]Medicine, Univ of Calgary, Calgary, AL, Canada.*

Background: Contemporary assessments of the validity and prognostic value of comorbidity indices in dialysis are lacking. We sought to assess the validity of two comorbidity indices used for dialysis patients and to determine if a high degree of comorbidity was associated with mortality.

Methods: We conducted a retrospective cohort study of incident chronic dialysis patients in a tertiary care institute from 2006-2013. The Charlson Comorbidity Index (CCI) and End-Stage Renal Disease Comorbidity Index (ESRD-CI) were calculated in all patients at dialysis initiation. These indices combine individual medical conditions into an overall score. Comorbid conditions were ascertained using electronic records. The primary outcome was all-cause mortality.

Results: The cohort consisted of 771 patients. Most were male (62%) and Caucasian (91%). Patients had a high prevalence of diabetes (48%) and history of myocardial infarction (31%). The c-index was 0.61 for the CCI, and 0.63 for the ESRD-CI. In an adjusted analysis, ESRD-CI scores of 4, 5 and ≥6 were associated with a similar mortality risk (Table 1). There was a small increased mortality risk for CCI scores of 4, 5 and ≥6.

Conclusions: The CCI and ESRD-CI had a limited ability to discriminate risk of death for incident dialysis patients. Although a higher comorbidity burden was associated with mortality, increases in index scores did not considerably change the risk of death.

Table 1. Multivariable Cox survival analysis for the ESRD-CI and CCI

End-Stage Renal Disease Comorbidity Index	
Score	*Relative Hazard [95% Confidence Interval]**
0/1	Reference
2	1.63 [1.12 to 2.36]
3	1.28 [0.84 to 1.91]
4	1.95 [1.34 to 2.85]
5	1.89 [1.25 to 2.86]
≥6	1.99 [1.41 to 2.81]
Charlson Comorbidity Index	
Score	*Relative Hazard [95% Confidence Interval]**
2	Reference
3	1.76 [1.10 to 2.82]
4	1.86 [1.22 to 2.83]
5	2.38 [1.53 to 3.72]
≥6	2.71 [1.81 to 4.06]

*Adjusted for age, sex, race, cause of end-stage renal disease, type of dialysis (hemodialysis or peritoneal dialysis), estimated GFR, albumin, phosphate and hemoglobin

FR-PO765

Cumulative Risk of Death in Propensity-Matched Incident Dialysis Patients: A Nationwide Prospective Multicenter Cohort Study in Korea Hee-Yeon Jung,[1] Sukyung Lee,[1] Ji-Young Choi,[1] Se-Hee Yoon,[2] Jang-Hee Cho,[1] Sun-Hee Park,[1] Chan-Duck Kim,[1] Yong-Lim Kim.[1] *[1]Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; [2]Internal Medicine, Konyang Univ, Daejeon, Republic of Korea.*

Background: Our previous study reported the superior outcome of peritoneal dialysis (PD) than hemodialysis (HD) in the early dialysis period. This study investigated the impact of dialysis modality after the early period of incident dialysis patients.

Methods: Incident dialysis patients were enrolled from Korean nationwide prospective cohort from September 2008 to December 2013. The patients were stratified by modality at day 90 after the first dialysis or the modality at dialysis initiation if death occurred prior. The survival of PD and HD patients were compared by propensity score matching analysis. Relative risk of death was estimated using the cumulative hazard ratio from the stratified Cox proportional hazard model adjusted for residual confounding.

Results: A total of 1348 patients were matched from 2658 incident dialysis patients with mean follow-up of 29.9 ± 14.1 months. All clinical parameters including baseline residual renal function were comparable between PD and HD patients. The cumulative risk of death was significantly lower in PD than HD from 6 months after dialysis initiation. The cumulative hazard ratio for death was 0.70 (95% confidence interval [CI] 0.41-0.98) at one year for PD compared with matched HD and 0.68 (95% CI 0.46-0.90) at two years. The cumulative survival probability was higher in PD patients for up to 3.5 years on dialysis, with no difference after the period.

Conclusions: Overall survival in maintenance dialysis patients favored PD in the early period of dialysis and the survival advantage lasted to 3.5 years after initiation of dialysis. However, PD and HD patients had similar survival outcomes thereafter.

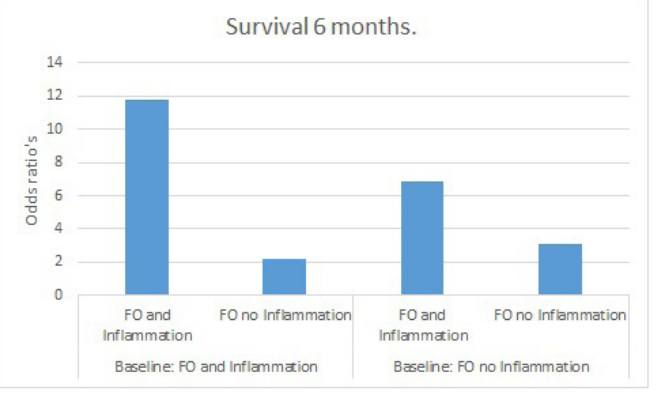
FR-PO766

Inflammation and Fluid Overload a Complex Interaction: Results from the International MONDO Initiative Marijke J.E. Dekker,[1] Len A. Usvyat,[2,3] Daniele Marcelli,[3] Frank van der Sande,[4] Constantijn Konings,[1] Peter Kotanko,[2] Jeroen Kooman.[4] *[1]Catharina Hospital Eindhoven; [2]Renal Research Inst; [3]Fresenius Medical Care; [4]Maastricht Univ Medical Center.*

Background: In hemodialysis (HD) patients, the presence of inflammation or fluid overload (FO) is associated with increased mortality. The combined presence of these two is associated with even a greater risk of death. This study aims to unravel the temporal relationship between fluid status alterations and inflammation.

Methods: We conducted a longitudinal study (baseline and follow-up 3 months each) in a European subset of the MONDO-Initiative. Fluid status was assessed by multifrequency bioimpedance and inflammation by C-reactive protein (CRP). We divided patients into 4 groups based on fluid- and inflammation status. FO was defined as overhydration above >2.5L. Inflammation was defined as CRP >10mg/L.

Results: We included 5954 patients (56.1% male, age 63 years, vintage 5.1 years). At baseline inflammation and FO were jointly present in 1092 (18.3%) patients. 141 (11.8%) developed inflammation during follow up. Of the 1192 (20%) patients with inflammation but with normal fluid status at baseline, 111 (10.2%) had FO during follow up. Inflammation at baseline predicted FO during follow up (odds ratio(OR) 1.20(95% CI 1.05-1.37)). Likewise, FO during baseline predicted inflammation during follow up (OR 1.30 (95% CI 1.15-1.47)). However, in a minor of patients the presence of FO and/or inflammation appears to be a relatively stable condition. The presence of both inflammation and FO during baseline was associated with an increased mortality risk compared to the absence of both.



Conclusions: FO and inflammation are associated in prevalent HD patients. FO is a predictor for inflammation and vice-versa inflammation predicts FO. The combined presence of FO and inflammation is associated with poor survival.

FR-PO767

Blood Volume Analysis as a Guide for Dry Weight Determination in Chronic Hemodialysis Patients Line Malha,[1,2] Hasan Fattah,[3] Frank Modersitzki,[1] David S. Goldfarb.[1,2] *[1]Internal Medicine, Div of Nephrology, NYU School of Medicine, New York, NY; [2]Internal Medicine, Nephrology Section, New York Harbor VA Healthcare System, New York, NY; [3]Internal Medicine, Div of Nephrology, Virginia Commonwealth Univ Medical Center, Richmond, VA.*

Background: Volume overload and depletion both lead to high morbidity and mortality. Achieving euvolemia is a challenge in patients with end stage kidney disease (ESKD) on hemodialysis (HD). Blood volume analysis (BVA) uses radiolabeled albumin to determine intravascular blood volume (BV). The measured BV is compared to an ideal BV (validated in healthy controls). We hypothesized that BVA could be used in HD to evaluate the adequacy of the current clinically prescribed "estimated dry weight" (EDW) and to titrate EDW in order to improve overall volume status. We were also interested in the reproducibility of BVA results in ESKD. This is the first longitudinal study of BVA in HD patients.

Methods: 12 adults on chronic HD were recruited; 10 completed the study. BVA (Daxor, New York, NY, USA) was used to measure BV at baseline. EDW was kept the same if the patient was deemed to be euvolemic by BVA otherwise, the prescribed EDW was changed with the aim that measured BV would match ideal BV. A second BVA measurement was done 1-3 months later in order to measure BV again.

Results: Based on BVA, 6/10 patients were euvolemic at baseline and 5/10 were euvolemic at the second measurement. When comparing patients who had their prescribed EDW changed after the initial BVA to those who did not, both groups had similar differences between measured and ideal BV (P=0.75). BV values were unchanged at the second measurement (P=0.34) and there was no linear correlation between BV change and weight change (r^2 =0.8).

Conclusions: This pilot study is the first longitudinal measurement of BVA in HD patients. It revealed that changing weight did not proportionally change intravascular BV. BV remained stable for 1-3 months. BVA may not be helpful in clinically stable HD patients but studies on patients with hemodynamic instability and uncertain volume status are needed.

Funding: Pharmaceutical Company Support - Daxor provided BVA equipment and supplies but was not involved in study design or execution and did not participate in the analysis of data or preparation of the manuscript

FR-PO768

Effects of Physician Payment Reform on Provision of Home Dialysis Kevin F. Erickson,[1] Wolfgang C. Winkelmayer,[2] Glenn Matthew Chertow,[1] Jay Bhattacharya.[1] *[1]Medicine, Stanford Univ, Palo Alto, CA; [2]Medicine, Baylor College of Medicine, Houston, TX.*

Background: Patients with end-stage renal disease can receive dialysis at home or in-center. In 2004 the Centers for Medicare and Medicaid Services reformed physician payment for in-center hemodialysis care from a capitated to a tiered fee-for-service model, augmenting physician payment for frequent in-center visits. We evaluated whether payment reform influenced dialysis modality assignment.

Methods: Using a national cohort of patients starting dialysis in the US in the three years before and after payment reform, we conducted difference-in-difference analyses comparing patients with Traditional Medicare coverage (who were affected by the policy) to others with Medicare Advantage (who were unaffected by the policy). We also examined whether the policy had a more pronounced influence on dialysis modality assignment in areas with lower costs of traveling to dialysis facilities.

Results: Patients with Traditional Medicare coverage experienced a 12% (95% CI, 2% to 21%) reduction in home dialysis use following payment reform compared to patients with Medicare Advantage. Patients living in areas with larger dialysis facilities (where payment reform made in-center hemodialysis comparatively more lucrative for physicians) experienced a 16% (95% CI, 8% to 23%) reduction in home dialysis use following payment reform compared to patients living in areas with smaller facilities (where payment reform made in-center hemodialysis comparatively less lucrative for physicians).

Conclusions: National physician payment reform intended to improve the quality of dialysis care resulted in fewer patients receiving home dialysis. This highlights a major failure of the policy and the importance of considering unintended consequences of future physician payment reform efforts.

Funding: NIDDK Support, Other NIH Support - Funding: F32 HS019178 from AHRQ (Dr. Erickson); DK085446 (Dr. Chertow); Dr. Winkelmayer receives research and salary support through the endowed Gordon A. Cain Chair in Nephrology at Baylor College of Medicine. Dr. Bhattacharya would like to thank the National Institute on Aging for support for his work on this paper (R37 150127-5054662-0002).

FR-PO769

Characteristics and Outcomes Amongst Patients Who Switch Dialysis Provider Scott Reule, Paul E. Drawz, Robert N. Foley. *Dept of Medicine, Univ of Minnesota, Minneapolis, MN.*

Background: Associations between provider switch and inferior clinical outcome have been demonstrated in primary care settings. It is plausible that similar associations extend into those on renal replacement therapy (RRT) as nephrology care often extends beyond that of RRT management alone. There is a paucity of literature available describing the characteristics and outcomes amongst those whom switch dialysis provider.

Methods: Using USRDS data, a change in provider will be defined the presence of any non-contiguous facility codes while receiving maintenance RRT. As patients transitioning to maintenance RRT may experience early adverse outcomes, only those patients having initiated RRT with a vintage of at least 1 year were included in the analysis. Means and proportions were calculated for continuous and categorical variables, respectively. Logistic regression was used for adjusted comparisons with adjustments for baseline demographic characteristic including age, sex, and race. All estimates with p-value < 0.05 were considered significant.

Results: Applying these criteria, a total of 187,510 (9.1%) of prevalent patients requiring RRT were identified as having changed provider at least once. The mean age of those who have changed provider (vs. no change) was 41.3 years (vs. 57.3 years), 57% were male (vs. 55.1%), 51.3% were white (vs. 49.1%), diabetes as comorbidity in 29.9% (vs. 49.4%), heart disease in 10.9% (vs. 21.1%), and 23.2% utilized peritoneal dialysis at initiation (vs. 9.75%). Risk of death was lower in those who change provider (OR 0.69; CI 0.68 – 0.70) and odds were higher for both listing for (OR 2.9; CI 2.9 – 3.0) and receipt of renal transplantation (OR 4.1; CI 4.0-4.2).

Conclusions: Patients who switch dialysis providers constitute a distinct population of patients who are younger and lack comorbid conditions frequency observed in those on dialysis. Compared to those who do not switch providers, those who switch are more likely to be listed for and receive renal transplant.

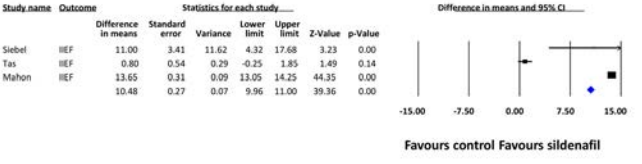
FR-PO770

Effects of Sildenafil in Dialysis Patients with Erectile Dysfunction: A Systematic Review and Meta-Analysis Anawin Sanguankeo,[1,2] Sikarin Upala.[1,2] *[1]Internal Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY; [2]Preventive and Social Medicine, Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.*

Background: Erectile dysfunction (ED) is prevalent in dialysis patients. Sildenafil, a PDE-5 inhibitor, has been shown to be very effective against ED in general population. However, there is some evidence that dialysis patients are resistant to sildenafil treatment. We performed this meta-analysis to evaluate efficacy of sildenefil in dialysis patients with ED compared with control.

Methods: We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published RCT comparing sildenafil therapy to placebo or controls on ED in patients with dialysis. The primary outcome was change in International Index of Erectile Function (IIEF) score. The diagnosisof ED was confirmed with a score of 21 or less in IIEF.

Results: From 153 full-text articles, 3 studies involving 153 dialysis patients were included in the meta-analysis. All included studies were RCT comparing sildenefil with active control in either hemodialysis or peridoneal dialysis patients. A meta-analysis using fixed-effects model was performed. Those who received sildenafil had a significant improvement in IIEF with a MD of 10.48 (95% CI: 9.96 to 11.00, p-value<0.01).



Conclusions: This is the first meta-analysis to show that sildenafil is effective in dialysis patients with erectile dysfunction compared with control. Further study comparing other benefits and side effects of PDE-5 inhibitor in dialysis patients should be conducted.

FR-PO771

Validation of Screening Questionnaires for Sleep Apnea in Hemodialysis Population Farhanah Yousaf, Mitesh K. Patel, Saw H. Mu, Alla Goldberg, Chaim Charytan, Bruce S. Spinowitz. *New York Hospital Queens.*

Background: Sleep apnea hypopnea syndrome (SAHS) is common in end stage renal disease (ESRD). We investigated the validity of Berlin and STOP-BANG questionnaires against nocturnal oximetry in identifying high risk hemodialysis patients for SAHS.

Methods: After obtaining local IRB approval, adult hemodialysis patients who were undergoing regular chronic hemodialysis for at least 3 months were consented and asked to complete Berlin and STOP-BANG questionnaires. Nocturnal oximetry from hemodialysis night using Pulsox 300i wristwatch was also completed. The saturation recordings were downloaded and analyzed using Profox software. The first hour of recording was deleted in efforts to capture oximetry reading from sleep time only. Motion artifacts and aberrant data were also excluded from analysis. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥ 3% from baseline lasting ≥ 10 seconds, per hour. Sensitivity, specificity, positive and negative predictive values were calculated for the Berlin and STOP-BANG questionnaires.

Results: Twenty HD patients (11 males and 9 females) aged 54 ± 13 years with a mean body mass index of 25.5 ± 4.6 kg/m^2 and neck circumference of 38.4 ± 5.8 cm participated in the study. ODI was ≥ 5 in 80% of patients. Both Berlin and STOP-BANG questionnaires had modest sensitivities (69-71%) but poor specificities (17-50%). Positive predictive value and negative predictive value was 67% and 67% for Berlin questionnaire, respectively. STOP-BANG questionnaire had a positive predictive value of 85% and a negative predictive value of 29%.

Conclusions: Reliable screening tools for SAHS in ESRD population are limited. Both Berlin and STOP-BANG questionnaires lack specificity to be utilized in this setting. Additional studies are warranted to elaborate the role of screening questionnaires for SAHS in end stage renal disease population.

FR-PO772

Moderate to Severe Nocturnal Hypoxemia and Executive Dysfunction in Patients Undergoing Maintenance Hemodialysis Farhanah Yousaf, Mitesh K. Patel, Chaim Charytan, Alla Goldberg, Bruce S. Spinowitz. *New York Hospital Queens.*

Background: Nocturnal hypoxemia and executive dysfunction is common in end stage renal disease. We investigated the impact of moderate to severe nocturnal hypoxemia on executive function in patients undergoing maintenance hemodialysis.

Methods: Following local IRB approval, adult hemodialysis patients were consented to complete 1 night of nocturnal oximetry using Pulsox 300i wristwatch. The first hour of recording was deleted in efforts to capture oximetry reading from sleep time only. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥ 3% from baseline lasting ≥ 10 seconds, per hour. Trail making tests A and B were also completed during dialysis session. Trail making test A and B performance was compared using t-test in patients with ODI < 15 versus those with ODI ≥ 15. Executive dysfunction was defined as trail making A and B completion time > 75 seconds and 180 seconds, respectively.

Results: Nine of 20 patients aged 45 ± 12 years with a mean body mass index (BMI) of 23 ± 3 kg/m^2 and neck circumference of 35 ± 4 cm had ODI < 15. The remaining eleven patients aged 60 ± 12 years with a mean BMI of 28 ± 5 kg/m^2 and neck circumference of 41 ± 6 cm had ODI ≥ 15. Patients with ODI ≥ 15 took significantly longer (77 ± 34 seconds) to complete trail making test A versus patients with ODI < 15 (45 ± 23 seconds). Five of 11 (45%) patients with ODI ≥ 15 required > 75 seconds to complete trail making test A compared to only 1 patient out of 9 (11%) with ODI < 15. Mean duration for completion of trail making B test was also longer in patients with ODI ≥ 15 (157 ± 87 seconds) compared to ODI < 15 (117 ± 67 seconds) [p=0.3]. Two of 11 patients with ODI ≥ 15 and 2 of 9 patients with ODI < 15 required > 180 seconds to complete trail making test B.

Conclusions: Patients with ODI < 15 performed better on trail making test A, were younger with a smaller BMI and neck circumference, compared to those with ODI ≥ 15. Additional research is warranted to confirm these findings. Whether treatment of moderate to severe nocturnal hypoxemia may slow or prevent executive function decline in patients undergoing maintenance hemodialysis remains to be determined.

FR-PO773

Indoxyl Sulfate (Indican) and Sleep Disorders in Hemodialysis Patients: The Retained Organic Solutes and Clinical Outcomes (ROSCO) Study Yunnuo Zhu,[1] Tanushree Banerjee,[1] Tariq Shafi,[2] Timothy W. Meyer,[3] Michal L. Melamed,[4] Thomas H. Hostetter,[5] Neil R. Powe.[1] *[1]UCSF; [2]JHU; [3]Stanford; [4]Albert Einstein; [5]Case Medical Center.*

Background: Although sleep disorders are common in dialysis patients, the pathophysiology of sleep disturbance is unclear. Protein-bound solutes inadequately removed during dialysis may contribute to sleep disorders.

Methods: We examined the association of total and free levels of IS with sleep disorder in 1,241 prevalent dialysis patients from the HEMO study. IS levels were measured using mass spectroscopy and modeled as tertiles. Sleep disorder was assessed using a 5-level categorical question in the Short Form (36) Health Survey. We used ordinal logistic regression to assess the relation of IS with sleep disorder, adjusting for confounders including age, race, gender, ICED score, body mass index, diabetes, congestive heart failure, serum albumin, creatinine, and phosphate levels. The lowest tertile of IS was the reference group. Effect modification was tested for IS levels with Kt/V and gastrointestinal (GI) disease (due to IS's GI origin).

Results: Patients were on average 57.5 years old, 62.8% were black, and 43.2% were male. There was a significant association between increasing tertiles of free IS and more severe sleep disorder in both unadjusted [OR 1.44 (95% CI: 1.1-1.89)] and adjusted models [1.78 (1.24-2.58)]. There was effect modification by Kt/V (p=0.03) but none by GI disease (p=0.17). Similar results were observed with total IS and sleep disorder [2.09 (1.37-3.19)]. Stratified analyses by Kt/V did not show an association between higher tertiles of free IS and sleep disorder in the high Kt/V group [0.72 (0.45-1.14)]. However greater odds of sleep disorder with highest tertile of IS were noted in the low Kt/V group. This relation was also present for total IS; those with low Kt/V had greater odds of sleep disorder with the highest total IS tertile [2.11 (1.29-3.45)] but not with the high Kt/V group [0.91 (0.61-1.35)].

Conclusions: Higher levels of IS are significantly associated with sleep disorder. Patients with a lower dialysis dose may be more susceptible. Further research on whether removal of IS improves sleep outcomes is needed.

FR-PO774

Quantifying Physical Activity Levels and Sleep in Hemodialysis Patients Using a Commerically-Available Activity Tracker Maggie Han,[1] Schantel Williams,[1] Anna Meyring-Wosten,[1] Viviane Calice-Silva,[1,2] Melissa Mendoza,[1] Hanjie Zhang,[1] Xiaoling Ye,[1] Stephan Thijssen,[1] Peter Kotanko.[1,3] *[1]Renal Research Inst, New York, NY; [2]Pontificia Univ Católica do Paraná, Curitiba, Brazil; [3]Icahn School of Medicine, New York, NY.*

Background: Hemodialysis (HD) patients are less active than their healthy counterparts (Johansen, Kidney Int, 2000). In addition, HD patients frequently experience poor sleep. Our aim was to objectively quantify activity and sleep quality in HD patients.

Methods: The number of steps taken and sleep data were collected by the Fitbit®Flex™ in ambulatory chronic HD patients for 5 weeks. A questionnaire was given at the end of the study. Sleep efficiency is defined as the ratio of sleep duration to time in bed.

Results: We collected data of 22 HD patients (55% males, 86% black, age 54±10 years). Average steps walked were 7,584±5,429 (Table 1). 36% of patients were sedentary, walking less than 5,000 steps per day. Patients walked 2,000 steps less on Sundays compared to the rest of the week (P<0.0001). Slightly more steps were taken on HD days. Patients slept less than 6 hours, which was significantly less than the NIH recommendation of 7 hours (P<0.0001). Sleep efficiency was 80±14%, significantly less than 85%, the lower limit of what is defined as poor sleep quality (P<0.05). When asked to what extent they agreed with the statement "I have walked more than usual", 36% replied "not at all", 23% replied "somewhat" or "moderately", and 41% replied "definitely" or "most definitely".

Table 1

Physical Activity[Steps/d]					Sleep Quality	
All Days	HD Day	Non-HD Day	Monday-Saturday	Sunday	Sleep Duration† [min/day]	Sleep Efficiency‡ [Sleep Duration/ time in bed]
7,584± 5,429	7,859± 5,007	7,390± 5,707	7,879± 5,508	5,851± 4.594**	340± 145**	80± 14%*

*P<0.05
**P<0.0001
†NIH recommends 420 min/day
‡<0.85 is poor sleep quality

Conclusions: The activity tracker was well accepted by patients. Programs and interventions to increase activity should target Sundays in particular. The described methodology may assist in identifying patients with poor sleep quality and facilitate the deployment of programs to improve sleep quantity and quality.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

FR-PO775

Using Decision Tree Analysis to Identify Risk Factors for Functional Impairment in Hemodialysis Patients J. B. Chen. *Div of Nephrology, Kaohsiung Chang Gung Memorial Hospital and Chang Gung Univ College of Medicine, Kaohsiung, Taiwan.*

Background: Hemodialysis (HD) patients frequently developed functional impairment. The study used decision tree analysis to identify risk factors for functional impairment in HD patients.

Methods: A total 1166 maintenance HD patients were enrolled in one hospital-based HD center. The observational period was from 2009 to 2013. Karnofsky Performance Status Scale (KPS) was used to quantify functional status. KPS assessment was based on HD nurse single visit yearly for consecutive five years. High KPS score was defined as ≥ 80 and low score as < 80. Decision tree analysis was used to analyze odds ratio (OR) of functional impairment from variables in demographics, laboratory test and primary renal disease classification.

Results: Subjects (853) with high KPS scores demonstrated significantly younger age (58.2 vs 71.3 years), longer HD duration (7.2 vs 4.7 years), higher nutritional indices, higher Kt/V (1.65 vs 1.59) and lower cardiothoracic (CT) ratio compared to subjects (313) in low KPS scores. A total 3509 KPS values were collected. 2697 (76.9%) values belonged to high functional scores, 812 (23.1%) values in low functional scores. The first variable chosen by decision tree analysis to split the data was age (67.5 years). There were six leaf nodes and twenty-eight subgroups. In age > 67.5 years group, the orders of consecutive chosen were serum albumin level (≤ 3.75 g/dL, OR 27.58, p= 1.77E-199), Cr level (≤8.93 mg/dL, OR 5.60, p =1.68E-37), HD duration (≤ 0.95 year, OR 39.40, p =1.68E-27), ferritin (>664.5 ng/ml, OR 26.26, p =2.06E-13), P level (>5.35 mg/dL, OR 9.28, p =8.88E-24), Hb level (>10.85 g/dL, OR 0.89, p =1.00). In age ≤67.5 years group, the orders of consecutive chosen were primary renal disease classification, Cr level (£10.43 mg/dL, OR 11.23, p= 2.03E-72), age (≤58.5 years, OR 1.65, p = 0.06), iPTH level (> 356.4 pg/ml, OR 0.44, p = 0.72), CT ratio (> 0.44, OR 11.16, p =9.17E-35).

Conclusions: : By decision tree analysis, age was the main risk factor for functional impairment in HD patients. Overall, the weight contribution of different risk factors for functional impairment in HD patients were identified by classification tree analysis.

Working Patients and Years on Dialysis: A Review Deborah S. Evans,[1] Duane V. Dunn,[1] Martha Donaho,[1] Laura M. Stewart,[1] Rich Mutell,[2] Paul J. Broughton,[2] Allen R. Nissenson,[1] Deborah A. Benner.[1] *[1]DaVita HealthCare Partners Inc, Denver, CO; [2]Apex Health Innovations, Simi Valley, CA.*

Background: Unemployment rates are high among dialysis patients; a 2011 study found approximately 71% of working-age dialysis patients are unemployed.[1] Another study found that dialysis negatively impacts employment status and has the largest effect between dialysis years 1 and 2.[2] We examined whether prolonged dialysis (dialysis vintage) affected employment status.

Methods: Dialysis vintage data and mean age were obtained from a sample of 16,069 employed patients from a large dialysis organization (Nov 2014-April 2015). Employment status was defined as regular full-time (³30 hrs/wk), regular part-time (<30 hrs/wk), and per diem (<24 hrs/wk).

Results: Regular full-time employed patients were older (52.6 yrs) than part-time (49.1 yrs) and per diem (49.0 yrs) patients. Employment status was highest among all patients for all categories of employment during year 1 of dialysis (35.7%) and dropped significantly by year 2 (14.4%) [Table]. Employment status continued to drop as vintage

increased and was lowest in the 10-year group (1.9%). Although there were more full-time employed patients in year 1 (42.4%) than part-time (28.3%) or per diem (28.9%), by year 10, only 1.3% remained employed full-time. Employment status rates were similar among per diem and part-time employees.

Table. Employment Status and Dialysis Vintage Among Surveyed Adult Dialysis Patients at a Large Dialysis Organization

Employment Status	Mean Age (years)		Years on Dialysis (Vintage)											Total
			1	2	3	4	5	6	7	8	9	10	10+	
Regular Full-Time	52.6	n	3553	1191	907	630	469	345	276	206	177	112	507	8373
		%	42.4	14.2	10.8	7.5	5.6	4.1	3.3	2.5	2.1	1.3	6.1	100
Regular Part-Time	49.1	n	1585	787	633	496	437	358	249	197	171	150	537	5600
		%	28.3	14.1	11.3	8.9	7.8	6.4	4.4	3.5	3.1	2.7	9.6	100
Per Diem <24 Hours	49.0	n	605	332	265	191	136	119	96	68	53	43	188	2096
		%	28.9	15.8	12.6	9.1	6.5	5.7	4.6	3.2	2.5	2.1	9	100
Total	50.2	n	5743	2310	1805	1317	1042	822	621	471	401	305	1232	16,069
		%	35.7	14.4	11.2	8.2	6.5	5.1	3.9	2.9	2.5	1.9	7.7	100

Conclusions: Our study found that dialysis vintage negatively impacts employment status and has the largest effect between years 1 and 2. Further study is needed to reveal if any underlying factors contribute toward this decrease, but these results should alert dialysis staff that support and intervention may be needed to help patients stay employed. References: 1) Muehrer RJ et al. Clin J Am Soc Nephrol. 2011;6(3):489-496. 2) van Manen JG et al. Perit Dial Int. 2001;21(6):595-601.

FR-PO777

Provider Visit Frequency During Hemodialysis and Its Effect on End Stage Renal Disease Comorbidities Juan E. Kusnir, Roberto J. Echeverri, Joslyn Wiley, Hazem Abu Grara, Rene Armando Garcia, Alberto J. Sabucedo, Marco A. LadinoAvellaneda. *Div of Nephrology, Miami VA Medical Center/Univ of Miami, Miami, FL.*

Background: In the United States, patients with End Stage Renal Disease (ESRD) on Hemodialysis visit their Nephrologist one to four times per month during their dialysis sessions. Medicare reimbursement policy encourages frequent provider visits for patients with ESRD on hemodialysis. We believe that increasing the number of face-to-face provider visits improves the care and clinical outcomes of comorbidities related to ESRD (hypertension, hyperphosphatemia, and hyperkalemia).

Methods: We used a Pre and Post-test pilot study design to evaluate the effect on laboratory measurements and blood pressure by increasing the frequency of Nephrologist face-to-face visits at the Miami VA Medical Center. Seventeen patients that were evaluated during a period of six months were included in the analysis. In the initial three months, the patients were evaluated four times per month (usual care). The number of face-to-face visits was increased to eight times per month (or twice weekly) for the following three months.

Results: A paired-sample t-test was conducted to compare the mean systolic blood pressure measure before and after the intervention. Additional provider face-to-face visits per month were associated with a significant difference in the systolic blood pressure before and after the intervention (p= 0.004, t=3.303, Mean=8.235, and Standard Deviation=16). In addition, we found improvement of the phosphorus levels with a difference that was statistically significant (p= 0.028, t=2.419, Mean=0.512, and Standard Deviation=16). Patients reported increased perceived quality of care when they had the opportunity of seeing the Nephrologist more frequently.

Conclusions: Hypertension and electrolyte abnormalities are known risk factors that increase morbidity and mortality in patients with End Stage Renal Disease. Adherence to medications is a major problem in patients on Hemodialysis therapy. Increasing the number of visits per month with the Nephrologist during Hemodialysis sessions increases adherence to a renal diet, medication use and patient satisfaction.

FR-PO778

Response Rate of Hepatitis B Virus Vaccination in Various Stages of Chronic Kidney Disease So Mi Kim,[1] Eun kyoung Lee,[2] Yun Jung Oh.[3] *[1]Divsion of Nephrology, Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Jejudo, Republic of Korea; [2]Divsion of Nephrology, Dept of Internal Medicine, Dankook Univ Hospital, Cheonan, Chungnam, Republic of Korea; [3]Divsion of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Jedudo, Republic of Korea.*

Background: Although hepatitis B virus (HBV) vaccination is recommended for all dialysis patients, the response rate of HBV vaccination in dialysis patients is very low. Therefore, we tried to investigate the necessity of early HBV vaccination in pre-dialysis patients analyzing the response rate of vaccination in various stages of chronic kidney disease (CKD).

Methods: A total of 87 patients in 3 different stages of CKD was enrolled in this study. Patients in stage 3 (n=30) and 4 (n=28) were received the HBV vaccine as standardized schedule, consisting of 1 mL of the recombinant vaccine, Hepavax-gene TF at 0, 1, and 6 months. And then, the patients with stage 5 (n=29) were received the same vaccine for doubling doses at 0, 1, 2, 6 months. Three months after each of the last vaccination, serum level of Anti-HBs was measured in all patients.

Results: There was no significant difference in baseline characteristics including age, sex, presence of DM among the 3 groups. The overall seroconversion rate after vaccination was 79.4 %. The seroconversion rate was significantly higher in patients with stage 3 than other patients (stage 3 : 94%, stage 4 : 79%, stage 5: 66%, p=0.031). Analyzing based on dialysis, seroconversion rate was also significantly higher in pre-dialysis patients than that in dialysis patients (pre-dialysis group : 86%, dialysis group: 63%, p=0.02). There was no significant factor to contribute seroconversion in multivariate analysis.

Conclusions: Our study showed the high seroconversion rate after HBV vaccination in CKD patients with stage 3 and pre-dialysis. Therefore, the HBV vaccination should be considered in early CKD stages.

FR-PO779

Hepatitis C Infection in Hemodialysis Patients Is Associated with Increased Anemia-Related Events in the DOPPS Brian Bieber,[1] Michel Y. Jadoul,[2] Paul Martin,[3] Takashi Akiba,[4] Chizoba Nwankwo,[5] Jean Marie Arduino,[5] Ronald L. Pisoni,[1] David A. Goodkin.[1] *[1]Arbor Research Collaborative for Health; [2]Univ Catholique de Louvain; [3]Univ of Miami; [4]Tokyo Women's Medical Univ; [5]Merck & Co., Inc.*

Background: Hepatitis C virus infection (HCV) remains common among hemodialysis (HD) patients, is associated with elevated mortality risk, and is rarely treated. The association of HCV with anemia-related events is not well characterized.

Methods: The Dialysis Outcomes and Practice Patterns Study (DOPPS) is a prospective cohort study of adult in-center HD patients (pts) in 21 countries, including nations recently joining the DOPPS (China, Russia, Turkey, Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates). We studied 67,290 pts in DOPPS phases 1-5 (1996-2015). Pts were considered to have HCV infection (HCV+) at DOPPS enrollment based on an established diagnosis of HCV infection or positive HCV serology. Associations of HCV with transfusions, GI bleed hospitalizations, and Hgb excursions below 8.5 g/dL were estimated via Cox regression (adjustments listed in table).

Results: HCV+ (vs. HCV-) pts were younger (58 vs. 63 yrs), had longer time on dialysis (3 vs. 8 yrs), and were more likely to have hepatitis B (8% vs. 2%) and cirrhosis (9% vs. 1%). Mean baseline Hgb levels for HCV+ pts were similar to HCV- pts (10.8 vs. 10.9 g/dL) and ESA doses by region were similar. In adjusted analyses, HCV+ pts were more likely to be transfused, be hospitalized for a GI bleed, and to have their Hgb drop below 8.5 g/dL (table).

Table: Anemia-related events for HCV+ vs. HCV- patients

Anemia Event	HCV status	N Events	Crude Rate[a]	Unadjusted HR[b] (95% CI)	Adjusted HR[c] (95% CI)
Transfusion[d]	+	237	48.2	1.33(1.16-1.52)	1.43(1.25-1.64)
	-	2600	43.7		
Hgb < 8.5 g/dL[e]	+	1399	239.1	1.11(1.02-1.20)	1.16(1.07-1.25)
	-	13726	208.5		
GI bleed[f]	+	103	12.8	1.16(0.93-1.45)	1.22(0.98-1.51)
	-	988	11.7		

a. Time to first event (per 1000 patient years)
b. Stratified by DOPPS country and phase and accounting for facility clustering
c. Stratified by DOPPS country and phase and accounting for facility clustering; adjusted for age, sex, time on dialysis, 13 summary comorbidities and hepatitis B infection, hemoglobin, albumin, phosphorus, creatinine, and ESA dose
d. N=46,395 patients; Excludes DOPPS phase 1 where transfusions were not included as an option on the hospitalization worksheet; In DOPPS 2-3 transfusions were only ascertained on the hospitalization worksheet (as inpatient or outpatient events); in phases 4 and 5, transfusion events were additionally captured every month on the interval summary; however, dialysis units may not be aware of or record all blood transfusions that their HD patients receive when transfusions occur outside the dialysis facility; US large dialysis organizations in DOPPS 4 and 5 were excluded due to differential reporting of hospitalization cause
e. N=59,253 patients; Restricted to patients with baseline Hgb ≥ 8.5 g/dL
f. N=67,290 patients

Conclusions: The disease burden of HCV+ pts on HD includes a greater likelihood of experiencing anemia requiring transfusion. The reasons for this are unclear but may include gastrointestinal blood loss due to portal hypertension as well as hypersplenism. Anemia in turn may contribute to a reluctance to initiate antiviral therapy for HCV infection.

Outbreaks of Hepatitis C Virus Infection Reported in U.S. Hemodialysis Facilities, 2008-2014 Duc B. Nguyen, Melissa Collier, Anne Moorman, Yury Khudyakov, Priti R. Patel. *US Centers for Disease Control and Prevention.*

Background: Hepatitis C virus (HCV) infection is more prevalent among hemodialysis (HD) patients than the general population. HCV transmission of in dialysis units may contribute, and is difficult to detect due to lack of symptoms and systematic screening. We summarized HCV outbreaks reported to CDC to characterize their frequency and factors contributing to transmission in HD facilities.

Methods: We defined a healthcare-associated outbreak as ³2 new HCV infections (positive anti-HCV £1 year after negative anti-HCV, or positive anti-HCV with acute hepatitis) in the same facility. We reviewed outbreaks in 2008–2014 reported to CDC. For HD unit outbreaks, we summarized type of facility, number of new cases, number of patients notified for HCV testing, infection control lapses identified, and results of HCV molecular testing. Intrafacility transmission was confirmed if there was epidemiologic and molecular evidence of transmission.

Results: During 2008–2014, 22 outbreaks of HCV infection in healthcare settings were reported to CDC; 11 (50%) of these outbreaks occurred in outpatient HD clinics. Seventy-nine (median 4, range 2–21) new HCV infections were identified. More than 1,800 HD patients were notified and screened for HCV in outbreak facilities. Intrafacility HCV transmission was confirmed in all 11 outbreaks. New cases had treatment time and location overlap with their HCV-infected source patient. For 9 outbreaks, lapses in infection control were identified, including environmental disinfection (8), hand hygiene (5), injectable

medication handling (3), separation of clean and contaminated workspaces (2), and vascular access care (1). Multiple lapses were identified in 7 outbreaks. No specific infection control lapses were identified at the time of the investigation in 2 outbreaks.

Conclusions: Outpatient hemodialysis clinics remain a common setting for healthcare-related HCV outbreaks. Infection control lapses were frequently identified in reported outbreaks. Rigorous adherence to recommended infection control practices is needed to protect patients and prevent future outbreaks in this setting.

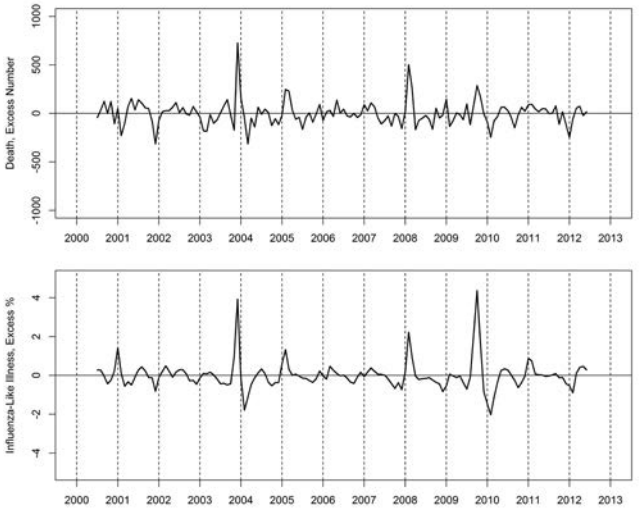
FR-PO781

Influenza and Outcomes in ESRD Patients David T. Gilbertson,[1] Anne C. Beaubrun,[2] Kenneth J. Rothman,[3] Jiannong Liu,[1] Brian D. Bradbury,[2] Akhtar Ashfaq,[2] Charles A. Herzog,[1] Allan J. Collins.[1] *[1]Chronic Disease Research Group, MMRF; [2]Ctr for Observational Rsrch, Amgen; [3]RTI Health Solutions.*

Background: Yearly influenza vaccination is recommended for all ESRD patients, due to a high risk of influenza-related complications. Through the CDC's Outpatient Illness Surveillance, information on patient visits to health care providers for influenza-like illness (ILI) is collected. These data give estimates of the percent of all OP visits that are for presumed influenza, and give national information on timing and severity of each influenza season. We assessed the association between CDC ILI data and outcomes in ESRD patients.

Methods: We aggregated weekly ILI data from 2000-2012 to monthly, and calculated the monthly number of deaths and hospitalizations among US ESRD patients during the same time period. Using time series decomposition, we subtracted out seasonal and trend components from both series, and computed correlations between the ILI and mortality/hospitalization data.

Results:



The figure displays deaths and ILI data after removing seasonal and trend components. There were 2 influenza seasons (2003-2004 and 2009-2010) during this time period where the peak was at the end of the calendar year (early in the influenza season) instead of at the beginning of the next calendar year. Similar "early" peaks are seen in deaths among ESRD patients. There is also correlation between other peaks and valleys of the ILI data and ESRD deaths; correlation coefficient = 0.63. Correlations were also calculated with cause-specific hospitalizations: 0.69 for ILI-influenza/pneumonia; 0.42 for ILI-any infection; 0.16 for ILI-MI; and 0.02 for ILI-stroke.

Conclusions: The association between ILI and outcomes in ESRD patients is strong. While influenza vaccination rates among ESRD patients have improved over the last decade, the overall rate is still below 70%, suggesting room for further improvement.

FR-PO782

The Burden of Pneumonia in Patients Receiving Dialysis: Incidence, Case Fatality, and Costs to Medicare Scott Sibbel,[1] Reiko Sato,[2] Abigail Hunt,[1] Wendy Turenne,[1] Steven M. Brunelli.[1] *[1]DaVita Clinical Research, Minneapolis, MN; [2]Pfizer Inc, Collegeville, PA.*

Background: End-stage renal disease patients receiving dialysis are at particular risk for infection. We assessed the clinical and economic burden of pneumonia in a population of Medicare-enrolled ESRD patients with respect to incidence and case fatality rates, rates of all-cause hospitalization, and costs.

Methods: Patients included in the analysis received dialysis between 01 Jan 2009 and 31 Dec 2011, and were enrolled in Medicare Parts A and B. Pneumonia episodes were identified from institutional and supplier claims. Patients were considered at-risk from the first date of Medicare coverage and were censored from the analysis upon transplant, withdrawal from dialysis, recovery of renal function or death. Linear mixed effects models were used to assess hospitalization rates and costs over the 3 months prior to and 12 months following a pneumonia diagnosis.

Results: The pneumonia incidence rate for the study period was 21.4 events/100 patient-years with the majority of episodes (90.1%) requiring inpatient treatment. The 30-day case fatality rate was 10.7%; case fatality rates were higher for older patients and for pneumonia requiring inpatient treatment (11.2%). All-cause hospitalization rates were greater in the month of the pneumonia episode vs month -3 prior to diagnosis (IRR, 4.61; 95%CI: 4.46, 4.76) and remained higher than baseline over the 1-year follow-up period. Mean per patient per month costs were $10,976 (95% CI: $10,717, $11,275) higher in the month of the index episode compared to month -3, largely driven by increased inpatient costs, and remained elevated through end of follow-up.

Conclusions: Pneumonia episodes are frequent among ESRD patients and result in hospital admissions and greater overall costs to Medicare (~$20,000 incremental) over the following year.

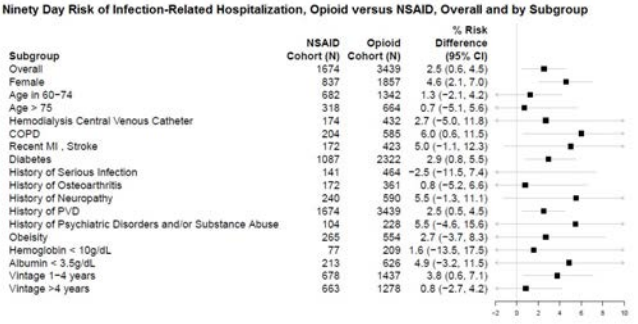
Opioid Use Associates with Infection Related Morbidity and Mortality in Hemodialysis Patients Abhijit V. Kshirsagar, Diane Reams, Magdalene M. Assimon, Anne Mobley Butler, Jennifer E. Flythe, M. Alan Brookhart. *Univ of North Carolina at Chapel Hill.*

Background: Opiates are frequently prescribed for pain in the US hemodialysis (HD) population but have intrinsic properties that increase risk of infection, a common cause of morbidity and mortality for patients. Data regarding the association of opioids with infection are lacking.

Methods: We conducted a retrospective cohort study using data from a large national dialysis provider linked with the United States Renal Data System and Medicare Part D (2006-2010). We used a new user design – comparing only new users of opioids to new users of prescription non-steroidal anti-inflammatory drugs (NSAIDS) to address confounding, as well as excluding patients with cancer, use of hospice services, or use of > 1 opiate. We assessed treatment effects on infection-related morbidity and mortality using inverse probability of treatment weighted Kaplan-Meier methods, adjusting for many comorbid, lab, and clinical variables.

Results: 5,113 patients met entry requirements, of which 3,439 (67.3%) received an opioid. Relative to new NSAID users, new opioid users had similar baseline laboratory values, but were slightly younger, and had a higher prevalence of comorbidities, including recent infections (8.7% vs 6.8%), diabetes (52.3% vs 49.3%), and chronic obstructive pulmonary disease (COPD), 17% vs 12.2%. After multivariable adjustment, we observed an elevated risk of 90-day infection-related hospitalization, (Risk Difference (RD) 2.5/100 patients, 95% CI 0.6-4.5) (Figure 1), and 90-day risk of infection-related mortality (RD 0.6%, 95% CI 0.3-0.9), no figure. For subgroups, infection-related hospitalizations were elevated among females and patients with diabetes, COPD, and lower dialysis vintage.



Conclusions: Our results suggest that opioid initiation increases the short-term risk of infection-related morbidity and mortality among HD patients.

A Retrospective Review of the Two-Step Tuberculin Skin Test in Manitoba's Dialysis Population

Rukhsana A. Foster,[2] Thomas W. Ferguson,[1] Claudio Rigatto,[1,2] Navdeep Tangri,[1,2] Blake R. Lerner,[2] Reid Whitlock,[1] Paul Komenda.[1,2] *[1]Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; [2]Medicine, Univ of Manitoba, Winnipeg, MB, Canada.*

Background: Reactivation of latent *Mycobacterium Tuberculosis* (LTBI) is a health concern for patients on dialysis due to their immunosuppressed state. The most frequently used test for LTBI screening in this population is the Tuberculin Skin Test (TST). The diagnostic accuracy (sensitivity and specificity) and clinical utility of the TST in a contemporary North American dialysis population is unknown.

Methods: We performed a retrospective cohort study of 483 hemodialysis and peritoneal dialysis patients across 4 dialysis units. All patients received a two-step TST and full TB risk assessment between February 2008 and December 2008. We then linked the cohort with the Manitoba Health TB Registry to ascertain if treatment was received for LTBI.

Results: At an induration cut-off of 5mm, 62 (13%) patients had a positive two-step TST. Patients with a BCG vaccination were more likely to test positive (50 vs. 34%, p = 0.05). Using a diagnostic gold standard of an abnormal chest X-ray as a proxy for LTBI, the sensitivity of the TST was only 13.9%, and the specificity was 87.7 %. Only 8 of 62 patients (13%) received treatment for LTBI. None of the patients who tested negative were treated.

Conclusions: The TST has limited diagnostic and clinical utility for LTBI screening in patients on dialysis. Further research into the diagnostic accuracy of interferon-gamma release assays, and a revision of LTBI screening guidelines in patients on dialysis should be considered.

FR-PO785

Reliability and Construct Validity of the Coping Strategy Inventory-Short Form in Hemodialysis (HD) Patients in 13 Countries in the Dialysis Outcomes and Practice Patterns Study (DOPPS)

Elodie Speyer,[1] Hal Morgenstern,[1,2] Yasuaki Hayashino,[3] Peter G. Kerr,[4] Hugh C. Rayner,[5] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health; [2]Univ of Michigan; [3]Tenri Hospital; [4]Monash Health & Monash Univ; [6]Birmingham Heartlands Hospital.*

Background: In international studies, questionnaires are often translated into several languages without consideration of cultural and linguistic differences that may compromise the reliability and validity of survey instruments, especially those measuring psychosocial factors. The Coping Strategies Inventory-Short Form (CSI-SF) is a 16-item questionnaire, developed in English, and previously validated in US cardiac failure patients. It is scored by computing 4 scales (each with 4 items) to measure 4 different coping strategies. The aim was to assess reliability and construct validity of the CSI-SF in HD patients across 13 countries.

Methods: The CSI-SF was self-administered to HD patients across 13 countries in 9 languages in DOPPS 4 (2009-11). Cronbach's alpha was used to assess internal consistency. Exploratory and confirmatory factor analyses were used to assess the factor structure of the CSI-SF by country and language.

Results: 6,656 HD patients completed the CSI-SF and were included in this analysis (55% male; median age=63, range: 18-96 yrs). Using the English version in 4 countries and the Swedish version, we found good internal consistency (α=0.63-0.77) for 3 of the 4 scales; the 4th scale was internally consistent if two items were dropped. In these countries, both types of factor analyses indicated a factor structure perfectly consistent with these same 4 scales. In the 8 other non-English versions, results were very different: internal consistency was lower for the 4 scales; no country showed an exploratory factor structure similar to that found previously, nor was the 4-factor structure confirmed with factor analysis.

Conclusions: The CSI-SF is reliable for measuring coping in HD patients in English and Swedish versions, as tested in the DOPPS. The importance of coping for predicting outcomes in HD patients can now be described in these countries. More research is needed for measuring coping strategies in other countries and languages.

FR-PO786

Associations Among Psychosocial/Medical Factors and Quality of Life in Hemodialysis Patients with End-Stage Renal Disease

Gun woo Kang. *Internal Medicine, Catholic Univ of Daegu School of Medicine, Daegu, Korea.*

Background: Patients with end-stage renal disease(ESRD) have a significant impairment in quality of life(QoL). Most previous studies have focused on medical factors mainly. However, quality of life can also be affected by psychosocial problems in the circumstances of chronic illness. The aim of this study was to identify the associations among psychosocial factors, medical factors and QoL in hemodialysis(HD) patients.

Methods: The study included 101 patients with ESRD who were undergoing HD(mean age 57.1 ± 12.1 years). Psychosocial factors were evaluated using the Hospital Anxiety and Depression Scale(HADS), Multidimensional Scale of Perceived Social Support, Montreal Cognitive Assessment and Pittsburgh Sleep Quality Index. In addition, for evaluating caregivers' burden in part of psychosocial factors, HADS and Zarit Burden Interview of main caregivers were administered. We also accessed medical factors(Kt/V and urea reduction ratio, etc.) with laboratory results(body mass index, albumin, hemoglobin, etc.). The QoL was evaluated using WHO Quality of Life-BREF(WHOQOL-BREF). Canonical correlation analysis was used to investigate the patterns of associations.

Results: The canonical correlation between psychosocial factor and QoL was significant. The first canonical correlation was 0.673(proportion = 60.6%, p = 0.001) and the second was 0.519(proportion = 26.9%, p = 0.006). However, the canonical correlation between medical factor and QoL was not significant(the first: p = 0.586, the second: p = 0.713).

Canonical function	Canonical correlation	Proportion	P-value
Between **Quality of life and medical factors**			
The 1st	0.436	0.382	0.586
The 2nd	0.412	0.332	0.713
Between **Quality of life and psychosocial factors**			
The 1st	0.673	0.606	**0.001**
The 2nd	0.519	0.269	**0.006**

Conclusions: The QoL of patients with ESRD was not associated with medical factor, but psychosocial factor in canonical correlation analysis. This finding may suggest that medical workers should recognize and treat psychosocial problems as well as clinical problems. We also would like to emphasize the comprehensive approach with cooperation between psychiatrists and nephrologists for improvement of QoL in ESRD patients.

FR-PO787

Longitudinal Associations of Dietary Protein and Energy Intake with Protein-Energy Wasting Syndrome in Hemodialysis Patients

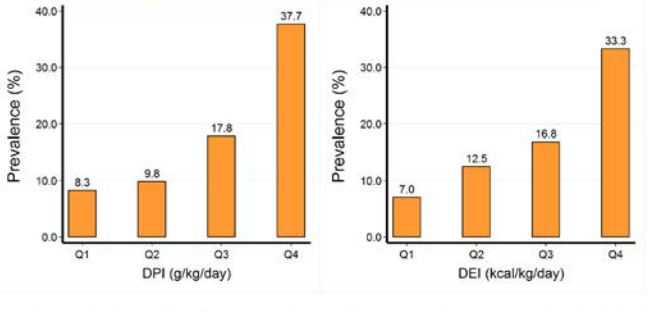
Srini Beddhu,[1,2] Xiaorui Chen,[1] G. Wei,[1] Robert E. Boucher,[1] Dominique Ferranti,[1] Kalani L. Raphael,[1,2] Tom Greene,[1] Michel Chonchol.[3] *[1]U of Utah; [2]VA SLC; [3]UC Denver.*

Background: Low dietary protein intake (DPI) (<0.6 g/kg/d) and low dietary energy intake (DEI) (<25 kcal/kg/day) are included in the definition of protein-energy wasting (PEW) syndrome. Therefore, we examined the longitudinal associations of baseline DPI and DEI with PEW syndrome (defined by modified criteria that excludes dietary variables) at 1 year of follow-up in 1480 MHD pts in the HEMO Study.

Methods: DPI and DEI were obtained by 24-h dietary recall. PEW syndrome at month 12 was defined as the presence of 2 out of the 3 criteria: serum chemistry (albumin by BCP method < 3.5 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 23 kg/m² or wt loss > 10% over 1 yr), and muscle mass (mid-arm muscle circumference 10% or more less than the 50th percentile of reference population). PEW syndrome at month 12 was related to baseline DPI and DEI in logistic regression models.

Results: 17.4% had PEW at month 12. The prevalence of PEW syndrome at month 12 by baseline DPI and DEI quartiles are summarized in the figure.

Figure 1 Prevalence of PEW syndrome by quantiles of DPI and DEI



The associations of baseline DPI and DEI with PEW syndrome at month 12 in logistic regression models are summarized in table.

Associations of baseline DPI or DEI with the presence of PEW syndrome at month 12*		
	OR (95% CI)	
	Model 1[$]	Model 2[#]
DPI<0.6 g/kg/d	0.39 (0.25, 0.62)	0.40 (0.26, 0.63)
DEI <25 kcal/kg/day	0.29 (0.21, 0.40)	0.30 (0.22, 0.41)
*Each cell represents a separate logistic regression model, [$] Adjusted for demographics, ESRD duration, Kt/V group, flux group, smoking and alcohol use, #Adjusted for above plus diabetes, CAD, CVD, PVD, CHF and arrythmias		

Conclusions: The contrarian finding of lower risk of PEW in those with low DEI and DPI could reflect mathematical coupling (as both DEI and DPI include body wt in the denominator and those with PEW have lower body wt).

Funding: NIDDK Support

FR-PO788

PEW Syndrome, Inflammation and Mortality in Hemodialysis Patients Srini Beddhu,[1,2] Xiaorui Chen,[1] G. Wei,[1] Robert E. Boucher,[1] Dominique Ferranti,[1] Kalani L. Raphael,[1,2] Tom Greene,[1] Michel Chonchol.[3] *[1]U of Utah; [2]VA SLC; [3]UC Denver.*

Background: The term 'malnutrition-inflammation complex syndrome' implies that malnutrition and inflammation are tightly interlinked. Therefore, we examined whether the mortality associations of markers of inflammation and protein-energy wasting syndrome (PEW) are attenuated by each other in 906 maintenance hemodialysis (MHD) patients in the HEMO Study, a multi-center RCT that examined the effects of dialysis dose and dialyzer flux on mortality.

Methods: High sensitivity Creative Protein (hsCRP), tumor necrosis factor (TNF)-a and interleukin (IL)-6 were measured in the month 12 stored samples. Weight loss was estimated from baseline and month 12 post-dialysis weights and hence, PEW syndrome at month 12 was defined as the presence of 2 out of 3 criteria: serum chemistry (albumin by nephelometry < 3.5 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 23 kg/m^2 or wt loss > 10% from baseline), and muscle mass (mid-arm muscle circumference 10% or more less than the 50th percentile of reference population). Cox models were used to relate month 12 PEW syndrome and hsCRP, TNF-a and IL-6 with subsequent mortality.

Results: Mean age was 57 ± 14 yrs. 45% were women. 67% were black. PEW syndrome was present in 17.4% at month 12. Median (IQR) serum hsCRP was 6.3 (2.6 -16.4) mg/L, IL-6 3.3 (2.0-7.6) pg/ml, and TNF-a 31.2 (21.3-46.1) pg/ml. There were 388 deaths over 2189 years of follow-up. PEW syndrome had 2 fold higher risk of mortality which was only marginally attenuated by adjustment for markers of inflammation (table). CRP and IL-6 were associated with higher mortality risk independent of PEW. TNF-a was not associated with mortality.

	Model 1*	Model 2*	Model 3*
PEW syndrome	2.22 (1.78, 2.76)	-	2.09 (1.68, 2.61)
Each doubling of CRP	-	1.10 (1.04, 1.17)	1.10 (1.03, 1.17)
Each doubling of TNF-a	-	1.04 (0.90, 1.19)	1.03 (0.90, 1.17)
Each doubling of IL-6	-	1.13 (1.08, 1.19)	1.12 (1.07, 1.18)

*Adjusted for age, gender, race, duration of ESRD, Kt/v group, smoking, alcohol use, DM, IHD, CVD, PVD, CHF and arrhythmia.

Conclusions: PEW and inflammation are independent predictors of mortality. These results suggest PEW and inflammation might not be tightly interlinked.

FR-PO789

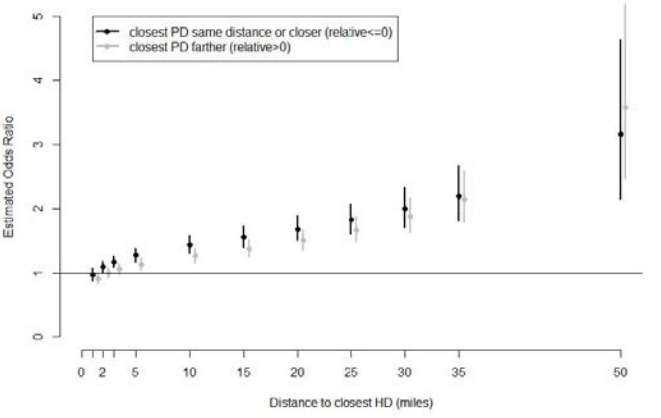
Impacts of Geographic Distance on Peritoneal Dialysis (PD) Utilization: Refining Models of Treatment Selection Virginia Wang,[1,2] Matthew L. Maciejewski,[1,2] Cynthia Coffman,[1,2] Linda L. Sanders,[1] Shoou-Yih D. Lee,[3] Richard Hirth,[3] Joseph M. Messana.[3] *[1]Duke Univ, Durham, NC; [2]Durham VA Med Ctr, Durham, NC; [3]Univ of Mich, Ann Arbor, MI.*

Background: Proximity to dialysis services may ease patient travel burden. Different frequency of visits to dialysis facilities and resulting differences in travel distance may affect patients' selection of hemodialysis (HD) versus PD. PD has historically been less commonly available in dialysis facilities and less commonly used than HD. We refine methods of prior research to reassess the relationship between patients' distance to dialysis care and modality choice to better reflect the conditions of patients' choice set of providers' location (absolute distance) and available services (relative distance).

Methods: Retrospective cohort of 70,131 patients initiating dialysis and 4,795 dialysis facilities in 2006 using USRDS data. The primary outcome was patient PD use. Independent variables included absolute distance from patients' home to nearest HD facility, relative distance dichotomized as the nearest PD facility closer or same distance as nearest HD facility, and their interaction. Logistic regression was used to model distance on PD use, controlling for patient and market factors.

Results: 9% of new dialysis patients used PD in 2006. There was a positive, non-linear relationship between absolute distance to closest HD services and PD use (p=0.0006). In terms of relative distance, odds of PD increased if a PD facility was closer or the same distance as the nearest HD facility (p=0.006). The interaction of absolute and relative distance was not significant.

Figure 1. Predicted Odds of PD Utilization. Estimated odds ratio and 95% confidence limits comparing absolute distance to closest HD facility from 1-50 to 0 miles to closest HD facility (in the same zip code) when distance to closest PD facility is either the same or closer than HD facility (black) or distance to closet PD is farther than closest HD (gray).



Conclusions: Distance is an important factor in patient decision-making when initiating PD, particularly for those living farther away from commonly offered HD services. Analyses of treatment selection must appropriately model distance to reflect logistics of treatment options and service availability to patients.

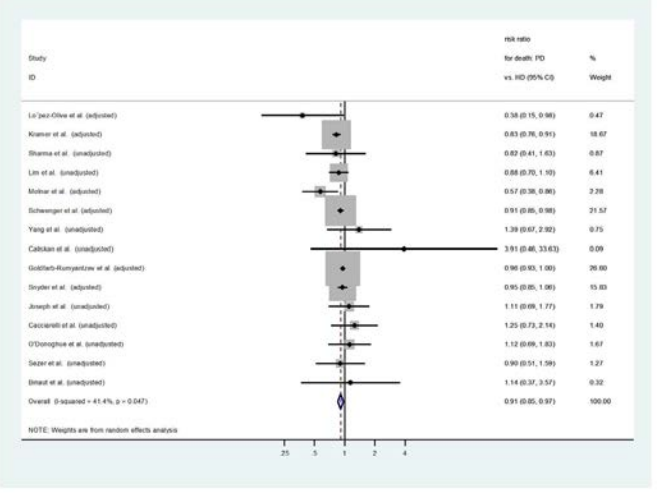
FR-PO790

Association of Pre-Transplant Dialysis Modality and Post-Transplant Outcomes: A Meta-Analysis Emily Joachim, Ali I. Gardezi, Sudheer Muduganti, Sana Waheed, Jung-Im Shin, Brad C. Astor, Micah R. Chan. *Univ of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: Patients who undergo dialysis prior to renal transplant have overall worse outcomes than patients who receive a preemptive transplant. However, individual studies give conflicting results regarding whether post-transplant outcomes differ based on pre-transplant dialysis modality (peritoneal dialysis (PD) versus hemodialysis (HD)).

Methods: We searched English-language literature from January 1, 1980 through August 31, 2014, national conference proceedings and reference lists of all included studies. We used combinations of terms related to dialysis (hemodialysis, peritoneal dialysis, or renal replacement therapy), kidney transplant and outcomes. Studies were included if they measured post-transplant patient mortality for both pre-transplant HD and PD. Studies were excluded if they were not in English or if they included pediatric patients.

Results: A total of 15 studies reported five-year patient mortality. These included 166,531 patients on HD and 51,980 patients on PD pre-transplant. The pooled hazard ratio for five-year patient mortality after renal transplant was 0.91 (CI 0.85-0.97) in favor of pre-transplant PD over HD (p=0.006).



There was moderate heterogeneity among these studies (I^2=41.4%, p=0.05). Six studies included an adjusted risk ratio (RR); the pooled RR for these studies was 0.89 (CI 0.82-0.97) in favor of PD (p=0.006). There was significant heterogeneity among these six studies (I^2=72.7%, p=0.003).

Conclusions: Based on these results, pre-transplant peritoneal dialysis is associated with better post-transplant survival at five years compared to hemodialysis. Further work should explore potential reasons for this difference and compare additional outcomes such as graft survival, delayed graft function and rejection.

FR-PO791

Impact of Poverty and Health Care Insurance on Pre-End Stage Renal Disease Care in Dialysis Patients Robert Nee,[1] Lawrence Agodoa,[2] Kevin C. Abbott.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]NIDDK, National Insts of Health, Bethesda, MD.*

Background: Access to nephrology care prior to end-stage renal disease (ESRD) is significantly associated with lower rates of morbidity and mortality. We assessed the association of area and individual-level indicators of poverty and types of health care insurance on pre-ESRD care provided by nephrologists.

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 739,537 patients initiated on maintenance dialysis from January 1, 2007 through December 31, 2012. We assessed the Medicare-Medicaid dual eligibility status as an indicator of individual-level poverty and ZIP code-level median household income (MHI) data obtained from the 2010 United States Census. We conducted multivariable logistic regression of pre-ESRD care as the outcome variable, as reported on the Centers for Medicare and Medicaid Services Form 2728.

Results: The proportions of dual-eligible and non-dual eligible patients who had pre-ESRD care were 53.06% and 61.82%, respectively (p<0.001). Dual-eligibility was associated with significantly lower likelihood of pre-ESRD care (adjusted odds ratio [aOR] 0.83; 95% confidence interval [CI] 0.82-0.84). Patients in the lowest area-level MHI quintile had an aOR 0.89 (95% CI 0.88-0.90) compared to those in higher quintile levels. Both African American (AA) and Hispanic patients were significantly less likely to have received pre-ESRD care (aOR 0.85, 95% CI 0.84-0.86 and aOR 0.71, 95% CI 0.70-0.72, respectively). Interaction terms for dual eligibility and AA race and Hispanic ethnicity were significant (p<0.001 and p=0.002, respectively).

Conclusions: Individual and area level measures of poverty were independently associated with lower likelihood of pre-ESRD care. Efforts to improve pre-ESRD nephrology care may require focusing on the poor and minority groups. Development and Validation of the Charlson Comorbidity Scoring System for Korean Incident Peritoneal Dialysis Patients Hyunjeong Cho,[1] Myoung-Hee Kim,[2] Seung Seok Han,[1] Jae Yoon Park,[1] Hyunjin Ryu,[1] Hyo Jin Kim,[1] Dong-Ryeol Ryu,[3] Hajeong Lee,[1] Jung Pyo Lee,[4] Chun Soo Lim,[4] Kook-Hwan Oh,[1] Kwon Wook Joo,[1] Yon Su Kim,[1] Dong Ki Kim.[1] *[1]Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; [2]Dental Hygiene, College of Health Science, Eulji Univ, Gyeonggi-do, Korea; [3]Internal Medicine and Ewha Medical Research Inst, School of Medicine, Ewha Womans Univ, Seoul, Korea; [4]Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea.*

Background: The Charlson Comorbidity Index (CCI) has widely used for predicting mortality and adjusting as a confounder in statistical analyses. However, the CCI remains disputed as an index to be applied to ESRD populations because the CCI was developed for general population. In this study, we modified the CCI and developed a modified Charlson comorbidity index in incident peritoneal dialysis patients (mCCI-IPD) to improve risk stratification for mortality.

Methods: The mCCI-IPD was developed based on 7,606 Koreans who received their first peritoneal dialysis treatment between 2005 and 2008. Data were obtained from the Korean Health Insurance dataset. The mCCI-IPD score was the sum of the weights which were assigned to individual comorbidities according to their relative prognostic significance determined by multivariate Cox proportional hazards model. The modified index was validated in an independent prospective cohort (n=664).

Results: The Cox proportional hazards model showed that the CCI comorbidities except ulcers, peripheral vascular disease, dementia and connective tissue disease significantly predicted mortality. Thus, the mCCI-IPD included 11 comorbidities with re-assigned severity weights. In the validation cohort, both the CCI and the mCCI-IPD were correlated with mortality. However, the analyses using continuous net reclassification improvement revealed that the mCCI-IPD improved net mortality risk reclassification by 30.8% (95% CI, 7.6-54.1; *P*=0.009) relative to the CCI.

Conclusions: The mCCI-IPD performed the better risk stratification for mortality in incident peritoneal dialysis patients than the CCI. It suggests that the mCCI-IPD may be a preferred tool for clinical study of peritoneal dialysis patients.

FR-PO793

Diabetes, Black Race, Female: Risk Factors for Hospitalization After Dialysis Start in a Nationwide Cohort Sample LaTonya J. Hickson,[1,2] Bjoerg Thorsteinsdottir,[2,3] Priya Ramar,[2] Jordan K. Rosedahl,[2] Cynthia S. Crowson,[2] Robert C. Albright,[1] Nana-Hawa Yayah Jones,[4] Rozalina G. McCoy,[2,3] Suzanne M. Norby,[1] Andrew D. Rule,[1] Amy W. Williams,[1] Nilay D. Shah.[2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Mayo Clinic Kern Center for the Science of Health Care Delivery, Mayo Clinic; [3]Primary Care IM, Mayo Clinic; [4]Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Young dialysis patients have a high frequency of hospitalizations and readmissions. Multiple factors likely contribute to this occurrence, but have not been fully elucidated.

Methods: Young, incident dialysis patients aged 20-44 years included in the US Renal Data System with first dialysis service in 2005-2011. Multivariable multinomial logistic regression models examined associations and interactions between baseline predictors and hospitalizations through claims in the first 3-15 months; all p-values <0.05.

Results: For 46,895 patients (mean age: 36; 58% male; 46% black, 48% white, 4% asian, 2% other race, 41% with diabetes, 23% with Charlson score ≥4) mean hospitalization rate was 2.3 per year. Subgroups for low to high utilizers included: 0 (45%), >0-4 (25%), >4-10 (20%) and >10 (10%) per year. Compared to the 0 hospitalization group, the >10 group had more females (48% vs 39%), more blacks (51% vs 45%), fewer Asians (2% vs 5%), more diabetics (52% vs 34%), more with Charlson score≥4 (41% vs 14%). Diabetics were more likely to be high utilizers (odds ratio [OR]: 1.98(1.84,2.14)) adjusting for age (OR:1.30(1.23,1.37) per 10 year decrease; sex (OR:1.23 (1.15,1.32) females vs males), black race (OR:1.24(1.16,1.34) blacks vs whites). Charlson score ≥4 were also more likely to be high utilizers (OR: 7.00(6.25,7.84) vs Charlson score 0-1), with highly comorbid females having nearly twice the risk as highly comorbid males (OR: 12.62 vs 6.23, interaction p<0.001) when compared to low comorbid males.

Conclusions: Hospitalizations are frequent among young incident dialysis patients, particularly among diabetics, blacks, females, and those with multiple comorbidities. Further investigation into socioeconomic factors and causes of hospitalizations is needed to clarify these finding for targeted interventions.

FR-PO794

Does Race Affect the Cause of Mortality in End Stage Kidney Disease? Luxme Nadarajah, Kieran Mccafferty, Muhammad M. Yaqoob. *Barts and the London, Nephrology, London, United Kingdom.*

Background: Cardiovascular disease accounts for 50% of mortality in end-stage kidney disease (ESKD). Caucasians (C) are more likely to die from cardiovascular disease, infection and withdrawal compared to Afro-Caribbean's (AC). Little is known about the causes of mortality for Indo-Asian (IA) patients; with the rise in diabetes mellitus (DM) it is inevitable that more patients from IA backgrounds will get ESKD. We aim to investigate whether there are any differences in causes of mortality based on race.

Methods: We performed a single center, prospective, observational study. Electronic case notes were used to extract data to include cause of death, age of initiation of RRT, age of death, dialysis vintage (DV), gender and presence of DM. Patients were excluded if RRT was less than 90 days, or if they were transplanted.

Results: In total 3431 patients commenced RRT during the study period, 802 patients died, 364 were C, 259 IA and 178 were AC. There were no significant differences between the groups for age at initiation, DV, and age of death. Significantly fewer IA died during the follow up period compared to C (p<0.0001) and AC (P<0.0001). More IA and AC were diabetic (p< 0.0001). Cardiovascular deaths were more common in C and AC patients compared to those of IA race (p=0.001). IA's had higher sepsis related deaths when compared C or AC (p< 0.0001).

	Caucasian	Indo-Asian	Afro-Caribbean
Total Number of patients	1055	1616	760
Number of deaths (%)	365 (34)	259 (16)	178(23)
Cardiovascular (%)	101 (28)	48 (19)	54 (30)
Sepsis (%)	79 (22)	97 (37)	36 (20)
Withdrawal (%)	68 (19)	48 (19)	34 (19)
Mailgnancy (%)	43 (12)	42(16)	17 (10)
CVA (%)	14(4)	8 (3)	10 (6)
Other (%)	59 (16)	16 (6)	27 (15)

Conclusions: Despite the increased prevalence in DM, IA patients do not have worse survival outcomes or cardiovascular deaths compared to C and AC. We believe that the elevated sepsis related mortality in IA patients is secondary to the higher prevalence of diabetes. This data enables stratifying management therapies dependent on race and may help in designing cardiovascular end points trials in racially diverse group of patients.

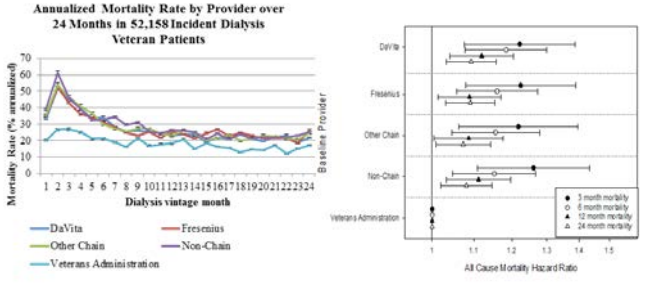
Association of Dialysis Provider Assignment with Early Dialysis Mortality in U.S. Veterans: A Transition of Care in CKD Study Elani Streja,[1] Melissa Soohoo,[1] Connie Rhee,[1] Vanessa A. Ravel,[1] Joline L.T. Chen,[1] Jennie Jing,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UTHSC.*

Background: Mortality is high during the first months after initiating kidney replacement therapy including in US veterans. Only 10% of veterans receive dialysis therapy in a Veterans Administration (VA) healthcare based dialysis clinic and the majority of veterans are assigned to non-VA centers and dialysis chains.

Methods: We examined all-cause mortality during the 3, 6, 12 and 24 month period after transition in a cohort of 52,158 US veterans who transitioned to ESRD over 4 years (10/2007-9/2011) and the association of dialysis provider assignment. Baseline provider was determined by facility information and divided into 5 categories: DaVita(DV), Fresenius(FR), Other Chain(OC), Non-Chain(NC), and VA. Associations were examined in Cox proportional hazard models and adjusted for age, gender, race, ethnicity, initial vascular access and primary cause of ESRD.

Results: Upon dialysis transition, patients were 70±12 yrs old, 6% female, 25% African-American, 19% initially used AV fistula and 42% had diabetes as the cause of ESRD. At baseline, 24%, 28%, 13%, 21%, and 10% of veterans received treatment at DV, FR, OC, NC, and VA facilities, respectively. Over the first 3, 6, 12 and 24 mos after transition, 5489(11%), 9283(18%), 14339(27%) and 21697(42%) veterans died, respectively (Figure left). Compared to patients initiating treatment at the VA, all patients receiving treatment at other facilities had higher risk of mortality through all periods of follow-up, after adjusting for case mix covariates (Figure right).



Conclusions: Veterans transitioning to dialysis treatment in a VA hospital based dialysis center have the best survival over the first 2 years of follow up. Whether the better survival of VA dialysis care is from selection bias versus true superior care in the VA system warrants additional studies.

FR-PO796

Time-Varying Racial/Ethnic Differences in Mortality After Initiation of Dialysis in U.S. Dialysis Patients Guofen Yan,[1] Keith C. Norris,[2] Alison J. Yu,[3] Tom Greene,[4] Jennie Z. Ma,[1] Wei Yu,[1] Alfred K. Cheung.[4] *[1]Univ of Virginia; [2]UCLA; [3]Univ of Southern California; [4]Univ of Utah.*

Background: While survival advantage for African Americans (AAs) and Hispanics, compared to Whites, has been observed for decades, our understanding of the mechanism is still incomplete. Using national dialysis patients, we examined whether this survival advantage exists across the entire course of ESRD or just within a certain time interval after initiation of dialysis.

Methods: The study included 1,255,640 adult incident dialysis patients between 1995 and 2010 in the USRDS. We calculated age-specific hazard ratios (HRs) of death for AAs and Hispanics vs. Whites, adjusted for covariates, for every 6-month interval in the first 4 years of dialysis and for the period thereafter.

Results: For each age group above 40 years (Table), lower risk of death for AAs than Whites (HR<1) did not vary greatly across these time intervals. In contrast, in each age group under 40 years, the HR for AAs vs. Whites evolved over time, which was highest in the first year, declined in the second year, and reached stable over time. Hispanics exhibited lower mortality risks in all age groups that remained relatively constant over time (not shown).

Table. Adjusted HRs for AAs vs. Whites

Age Groups	Months after Initiation of Dialysis								
	1 – 6	7-12	13 – 18	19 – 24	25 -30	31 – 36	37 – 42	43 – 48	>48
18-30	1.72	1.50	1.14	1.28	1.09	0.92	0.91	0.93	0.93
31-40	1.34	1.32	1.07	0.92	0.86	0.89	0.68	0.72	0.83
41-50	0.89	0.93	0.85	0.76	0.72	0.71	0.70	0.68	0.78
51-60	0.76	0.74	0.70	0.69	0.66	0.66	0.65	0.67	0.76
61-70	0.72	0.73	0.70	0.70	0.70	0.68	0.68	0.71	0.81
71-80	0.76	0.80	0.74	0.76	0.76	0.77	0.78	0.79	0.86
>80	0.84	0.83	0.80	0.78	0.83	0.85	0.81	0.84	0.88

Note: most of these HRs were significant at p<0.05.

Conclusions: AAs over 40 years old and Hispanics of all ages have uniformly lower risks of death than Whites across the course of ESRD. For younger AAs, conversely, their higher-mortality risk period is limited to the first two years of dialysis. Further studies to delineate the factors responsible for excessive mortality associated with racial subgroups will improve care for all dialysis patients.

Funding: NIDDK Support

FR-PO797

Real Threat of ESRD in China: A Ten-Year Experience from Nanjing 3 Million Insurance Covered Population Yu-Chen Han,[1] Ling Sun,[1] Han-Ming Huang,[2] Kun ling Ma,[1] Bei Wang,[3] Bi-Cheng Liu.[1] *[1]Zhongda Hospital, Southeast Univ School of Medicine, Nanjing, Jiangsu, China; [2]Nanjing Municipal Human Resources and Social Security Bureau, Nanjing, Jiangsu, China; [3]Southeast Univ School of Public Health, Nanjing, Jiangsu, China.*

Background: In the past decade, Chinese government has made great efforts to provide an affordable and equitable access to renal replacement therapy (RRT) for most of ESRD patients. Here we analyzed the ten years registry data of 3 million Nanjing Urban Employee Basic Medical Insurance (UEBMI) covered population and firstly provided the epidemiological data about ESRD in this developing country.

Methods: Using the electric registry system of UEBMI, we included all subjects insured by UEBMI in Nanjing from 2005 to 2014, and identified subjects who developed ESRD in this cohort. The prevalence and incidence of ESRD was analyzed based on this unique data system.

Results: During the 10-year period, the incidence rate of ESRD in UEBMI cohort in Nanjing gradually declined from 289.3pmp in 2005 to 218.8pmp in 2014. However, the prevalence rate increased steadily from 891.7pmp in 2005 to 1228.6pmp in 2014. The annual mortality rate declined from 138.4 per 1000 patient-years in 2005 to 97.8 per 1000 patient-years in 2014. Long-term survival rate of ESRD fluctuated during the past decade, with 1-year survival rate ranging from 85.1% to 91.7%, 3-year survival rate from 69.9% to 78.3% and 5-year survival rate from 58% to 65.4%.

Conclusions: This study firstly provided an epidemiological data about ESRD based on the complete electric registry data system in large population in China. Due to the lack of a national complete registry data system, the real burden of ESRD in China is still unclear. Nanjing is one of the biggest cities in China. Our present study based on the ten years complete electric registry data system provided a convincing data about the real threat of ESRD in China. According to this study, we estimated that China will probably have over 1.5 million ESRD patients in the near future with the establishment of improved healthcare system. It is therefore utmost important for both medical communities and government to take active measures to control this coming disaster.

Funding: Government Support - Non-U.S.

FR-PO798

An Evaluation of Completeness of Monthly Clinical Data in CROWNWeb, a New Data Source for the United States Renal Data System (USRDS) Valarie B. Ashby,[1] Lingqun Liu,[1] Xizhao Li,[1] Tempie H. Shearon,[1] Bruce M. Robinson,[2] Douglas E. Schaubel,[1] Yi Li,[1] Rajiv Saran.[1] *[1]Univ of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: CROWNWeb (CW) is a web-based system which collects administrative and clinical data from all Medicare-certified dialysis facilities in the US. It includes patient admission, tracking, and discharge information, CMS forms, and clinical data elements, and is not limited to Medicare patients. Monthly clinical data submission began in May 2012. Previously, monthly clinical data were only available to the USRDS through administrative claims for Medicare patients.

Methods: CMS data were used to analyze 355,846 and 370,610 dialysis patients in 2013 and 2014, respectively, who remained on dialysis the entire year (those who were incident, died, or lost to follow-up were excluded). The percentages of patients with any and high-level reporting of selected CW clinical data were calculated, with 'high-level' defined as 10+ months (except 3+ months for peritoneal dialysis (PD) Kt/V). The percentage of high-level reporting for patient subgroups was also calculated.

Results: The percentages of patients with CW data (any, high) are shown below. All measures had an increase in reporting from 2013 to 2014. High-level reporting in 2014 ranged from 75% (Hemodialysis (HD) Kt/V) to 90% (vascular access type). For all measures, reporting was higher for HD than PD patients, for adults than children, and for patients with (versus without) diabetes as cause of ESRD. 72% of HD patients had high-level reporting for all 6 HD measures. 70% of PD patients had high-level reporting for all 5 PD measures.

	2013		2014		High Level Reporting By Subgroup in 2014					
Clinical Data	Any	High	Any	High	HD	PD	Pediatric	Adult	No DM	DM
Serum albumin	88.4%	79.4%	92.9%	87.0%	87.8%	83.9%	72.0%	87.0%	85.1%	89.3%
Calcium	90.2%	81.0%	93.7%	87.7%	88.6%	84.2%	72.8%	87.7%	85.9%	90.0%
Phosphorus	92.4%	82.9%	94.0%	88.0%	88.9%	84.3%	73.6%	88.0%	86.1%	90.3%
Hemoglobin	83.2%	78.8%	90.8%	86.3%	87.6%	80.2%	69.2%	86.3%	84.6%	88.5%
Vascular Access Type*	94.5%	88.0%	94.8%	89.8%	89.8%	.	81.7%	89.8%	88.1%	91.9%
HD Kt/V*	60.4%	57.7%	78.7%	74.8%	74.8%	.	66.6%	74.8%	73.2%	76.7%
PD Kt/V**	70.4%	59.9%	82.0%	81.3%	.	81.3%	65.2%	81.6%	80.5%	82.8%

*Vascular access type and HD Kt/V are based on 315,850 (2013) and 326,736 (2014) HD patients.
**PD Kt/V is based on 25,311 (2013) and 28,514(2014) PD patients. The High level percentage is based on 3 or more months since PD Kt/V is only recommended to be collected every 4 months (3 times per year)

Conclusions: CW is now an integral part of the USRDS. Our study suggests a generally high and improving level of completeness of clinical data elements in CW. These data will enhance the value of the USRDS database for researchers in coming years.

FR-PO799

Facility Size and Impact of Extreme Measure Values on DFC Star Ratings

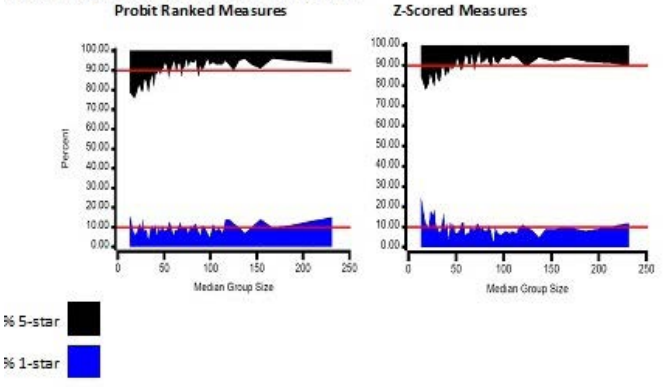
Christopher J. Harvey,[1] Claudia Dahlerus,[1] Zezhi (zac) Zhang,[1] Joseph M. Messana,[1] Ji Zhu,[1] Cindy Liao,[1] Natalie Scholz,[1] K. A. Wisniewski,[1] Richard Hirth,[1] Elena K. Balovlenkov,[2] Joel S. Andress,[2] Yi Li.[1] *[1]Biostatistics, Kidney Epidemiology and Cost Center, Univ of Michigan, Ann Arbor, MI; [2]Centers for Medicare and Medicaid Services.*

Background: In 2015 CMS implemented star ratings for dialysis facilities to make it easier for consumers to compare dialysis facilities by providing a summary of each facility's performance on a set of 9 DFC quality measures. Our study compares two scoring approaches to the star rating to assess the impact of each on controlling outlying measure values with regard to facility size.

Methods: Fixed percentiles are applied to assign 10% of facilities 1-star or 5-stars based on performance. 2013 data were extracted from the 2015 January DFC file. Probit ranking and z-score transformation were applied to the DFC measures to develop an overall score and final star rating. We compared the final distribution of star ratings for each approach and assessed impact on smaller facilities. We represent the rating by number of patients in each facility contributing to the hospitalization measure, and split ~6000 facilities into groups of ~100 and calculated percentage of each star rating in each group.

Results: Use of original measure values and z-scores allowed skewed measures to highly influence the ratings, but preserved original measure distributions. Probit ranking resulted in giving more 5-star ratings to smaller facilities and z-scored approach resulted in assigning more 1-star and 5-star ratings to smaller facilities (Figure 1).

Figure 1: Distribution of Star Ratings by facility size



Conclusions: Small facilities have more variation in measures and be over represented in the 1 or 2-star categories. Probit ranking (current DFC Star Rating method) controlled impact of outlier measure values. Z-score methods appeared to allow greater impact of extreme values. However, facility size may also be related to quality of care.

FR-PO800

P11 as Marker and Vitamin D as Treatment Option of Depression in Maintenance Dialysis Patients

Ga Hee Lee, Sihyung Park, Bongsoo Park, Kyubok Jin, Yang Wook Kim. *Haeundae Paik Hospital.*

Background: Depression is a disabling condition impairing all aspects of human functions. The serotonin system has been implicated in the pathophysiology of depression. Recently, as a member of the S100 family of proteins, P11 is known to have relation to depression by interacting with serotonin receptors and affected by inflammation. Because of nutritional deficiency and limited physical activities, dialysed patients are easy to have vitamin D deficiency. Recent studies reported that vitamin D might play a role in depression. So, we planned this study to assess the possibilities of the P11 as a depression marker and the vitamin D as a treatment option in dialysed patients.

Methods: As a single center cross-sectional study, we examined the peripheral blood mononuclear cells P11 mRNA, IL-6, TNF-α, 25-hydroxycholecalciferol (25-(OH)D_3) of patients with hemodialysis (HD, N=27), peritoneal dialysis (PD, N=39) and healthy group (N=7). Groups were divided by presence of depressive mood and categorized by severity of depressed mood via Beck Depression Inventory (BDI).

Results: In non-depressive group (BDI <10), The dCt means of P11 were high in HD group (5.51 ± 0.7 (HD, N=15) vs. 1.39 ± 0.33 (PD, N=11) and 2.29 ± 0.37 (control, N=7), p <0.05). The mean IL-6 levels were low in control group (6.43 ± 1.34 pg/mL (HD) and 7.53 ± 1.39 pg/mL (PD) vs. 2.23 ± 0.49 pg/mL (control), p <0.05). The mean TNF-α levels were low in control group (4.31 ± 0.26 pg/mL (HD) and 4.15 ± 0.25 pg/mL (PD) vs. 1.85 ± 0.53 pg/mL (control), p < 0.05) respectively. In depressive group (BDI ³10), P11 levels showed relationships with depression severity in peritoneal dialysis group (spearman rho=0.2, p =0.09). In hemodialysis group, 25-(OH)D3 level was lower in depressive group (11.98 ± 3.8 vs. 7.5 ± 2.7, p = 0.005), but there was no difference in peritoneal dialysis group (6.3 ± 3.3 vs. 7.4 ± 7.1, p=0.55).

Conclusions: By diagnostic tool, P11 can be used in peritoneal dialysis group as a depression marker despite taking the effect of inflammation into consideration, but not in hemodialysis group. As other treatment option, 25-(OH)D3 can be used in hemodialysis group for depression management, but not in peritoneal dialysis group.

FR-PO801

Efficacy of Loop Diuretics in the Management of Undocumented End Stage Renal Disease Patients Receiving Emergency Hemodialysis

Salman Ahmed, Biruh Workeneh. *Dept of Internal Medicine, Section of Nephrology, Baylor College of Medicine, Houston, TX.*

Background: Nearly eleven million undocumented immigrants reside in the United States. An estimated six thousand undocumented patients suffer from End Stage Renal Disease (ESRD). These patients routinely present to public hospitals for life-saving emergent dialysis treatments. Since these patients lack a dialysis unit, they often do not have medication management by a nephrologist. This can result in poorer outcomes.

Methods: We reviewed charts of 93 undocumented patients who presented for at least three emergent hemodialysis (HD) treatments during three consecutive months to the Ben Taub General Hospital, a centrally located county facility in Houston, TX. We abstracted prescription data for furosemide and several commonly prescribed medications. We also abstracted data regarding the number of ER visits, number of HD sessions, and mean, median, and peak potassium values.

Results: On average, the diuretic group had 3.1 (SE=1.8) fewer ER visits during the three-month period for emergency dialysis, compared with subjects not on diuretics (p=0.10). There was no significant relationship between furosemide total daily dose (TDD) and potassium levels. Patients on diuretics were more likely to also be taking ESAs and sevelamer (P£0.05). In a multiple regression model, the diuretic group had significantly fewer ER visits after adjusting for use of ESAs and sevelamer use (p=0.007). The association between diuretic use and ER visits is significantly associated with concomitant ESA use (p=0.04). Among subjects using ESAs, patients on diuretics have about 7.7 (95% CI: 1.9,13.6) fewer ER visits compared with the non-diuretic group.

Conclusions: There was no significant independent association between loop diuretic dosage and number of ER visits, although there was a strong trend. The subset of patients on ESAs *and* loop diuretics had decreased ER utilization, and this may be explained by increased doctor-patient time, less symptomatology while on ESAs, or other, as-yet-undetermined mechanisms.

FR-PO802

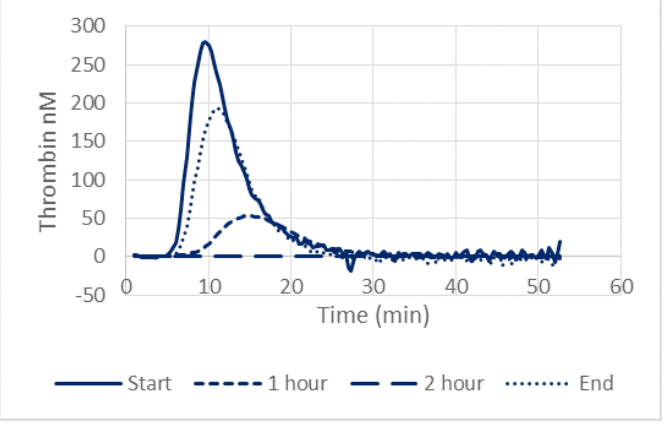
Unfractionated Heparin May Contribute More to Dialysis-Associated Bleeding Risk Than Low-Molecular Weight Heparin

Suzanne H. Forbes,[1] Sean Platton,[2] Michael K. Almond,[3] Laura Green,[2] Neil Ashman.[1] *[1]Nephrology, Royal London Hospital; [2]Haematology, Royal London Hospital; [3]Nephrology, Southend Hospital.*

Background: Haemodialysis (HD) patient are well recognised to be at increased risk for major bleeding. The contribution of circuit anticoagulation to this risk is unknown. The use of unfractionated heparin (UFH) vs low-molecular weight heparin (LMWH) is debated. APTT/anti-Xa levels suggest anticoagulation is cleared by the end of HD but these tests are poorly correlated with bleeding phenotype. We used thrombin generation (TG) to assess coagulation throughout HD with UFH or LMWH.

Methods: We studied 127 patients; 60 LMWH, 61 UFH, 6 heparin-free. Blood was taken at t0=pre-anticoagulation, t1=1hr, t2=2hrs, t3=end. TG was performed on platelet poor plasma, measuring lag time, exogenous thrombin potential (ETP) & peak thrombin.

Results: Results are shown in table 1. With LMWH 42% failed to generate thrombin at t3 compared with 57% of UFH, indicating significantly impaired clotting (p=0.05). In those who did generate thrombin at t3, this was considerably below baseline.



The magnitude of this was significantly greater with UFH for lag time (p=0.03), ETP (p=0.06) and peak thrombin (p=0.05). Heparin-free patients showed minimal change.

	UFH	LMWH	Heparin-free
t0			
Lag	4.53	4.63	4.88
ETP	1960	2153	2037
Peak Thrombin	226	325	291
Platelet Count	226	190	248
Hb	10.4	10.7	9.46
Average anticoagulation dose	Bolus 1328u Infusion 991u/hr Lockout time 33mins	3129iu	-
%change t0: t3			
Lag	↑71	↑41	↑10
ETP	↓35	↓29	↓1
Peak	↓65	↓48	↓2

Conclusions: Standard HD anticoagulation results in impaired haemostasis after HD as measured by TG, UFH more so than LMWH, which is not seen in heparin-free patients. This shows the HD process itself does not impact TG, rather exogenous anticoagulation. This should prompt cautious anticoagulation use, especially UFH, in patients at risk of bleeding.

FR-PO803

Anti-Platelet Factor 4 Antibodies: A One HIT Wonder Suzanne H. Forbes,[1] Sean Platton,[2] Michael K. Almond,[3] Neil Ashman,[1] Laura Green.[2] *[1]Nephrology, Royal London Hospital; [2]Haematology, Royal London Hospital; [3]Nephrology, Southend Hospital.*

Background: Hemodialysis (HD) patients are exposed to regular anticoagulation, usually unfractionated heparin (UFH) or low-molecular weight heparin (LMWH). For standard HD (4 hrs, 3 days/week) this equates 26 full days exposure/yr. Recently there was interest in the presence of heparin induced thrombocytopenia (HIT) in HD, and the causative anti-platelet factor 4 (PF4) antibody. There are several publications suggesting the presence of the antibody, without the clinical syndrome of HIT, is present in up to 25% HD patients, and may be an independent risk factor for cardiovascular and vascular access morbidity.

Methods: We looked for HIT antibodies in 2 prevalent HD cohorts, one with UFH, one LMWH (line lock sodium citrate). We tested serum for anti-PF4 antibodies using several established tests; STic Expert® (IgG-specific exclusion test), Diamed (particle gel immuno-assay), poly-specific IgGA/M ELISA, IgG-specific ELISA.

Results: We included 127 patients: 60 receiving tinzaparin, 61 receiving UFH and 6 dialysing heparin-free. Serum samples were taken at the start of a standard HD session. The average duration on dialysis was 3.4 years. Results of the various tests are shown.

TEST	UFH	LMWH	Heparin-free
Platelet Count	226	190	248
STic Expert	positive - 52% negative - 48%	positive - 40% negative - 60%	positive - 0% negative - 100%
Diamed	positive - 1% negative - 99%	positive - 1% negative - 99%	negative - 0% positive - 100%
Poly-specific ELISA	median OD - 0.2 (positive>0.4)	median OD - 0.15 (positive>0.4)	median OD - 0.09 (positive>0.4)
IgG specific ELISA	median OD - 0.13 (positive>0.4)	median OD - 0.07 (positive>0.4)	median OD - 0.05 (positive>0.4)

Only 1 patient tested antibody positive (OD 0.5) in the LMWH group. Platelet count and reactivity (using ADP, epinephrine, collagen) did not differ between the STiC positive/negative groups, the UFH/LMWH groups, or those with higher or lower tertiles of ELISA OD.

Conclusions: Despite the previously reported concern over the presence of HIT antibodies in HD patient, we comprehensively show here no evidence of antibody positivity in HD patients. Exclusion tests such as STiC expert are not useful in these patients.

FR-PO804

Upper Gastrointestinal Bleeding Among Dialysis Patients in an Endemic Area for Chronic Liver Disease: Taiwan National Cohort Study Chih-Chiang Chien,[1,2] Chien-Ya Hung.[1] *[1]Chung Hwa Univ of Medical Technology, Tainan, Taiwan; [2]Chi Mei Medical Center, Tainan, Taiwan.*

Background: End-stage renal disease (ESRD) and chronic liver disease (CLD) both increase the risk for upper gastrointestinal (UGI) bleeding. The prevalence of ESRD and CLD are high in Taiwan. The aim of this study was to evaluate the incidence, risk factors, and categories of UGI bleeding in ESRD dialysis patients.

Methods: Using Taiwan's National Health Insurance research database, we enrolled 42,457 incident ESRD dialysis patientswho began dialysis between 1999 and 2004. The patients were followed until death, dialysis cessation, or 31 December 2008. Cumulative incidence of UGI bleeding after initiation of dialysis was calculated using Kaplan-Meier methods. Predictors for UGI bleeding were determined using Cox models.

Results: During the follow-up period, 5,528 patients had a UGI bleeding. Male, elderly, receiving hemodialysis (HD) and patient with comorbidites had a higher rate of UGI bleeding. The 1-, 3-, 5- and 7-year cumulative incidence rate of UGI bleeding were 9.8%, 21%, 25.3% and 28% in patients with liver cirrhosis (LC) on HD, 5.8%, 16.2%, 22.2% and 24.4% in patients with LC on PD, 3.7%, 9.2%, 13.2% and 16.4% in patients without LC on HD, and 2.1%, 5.5%, 8.2% and 10.4% in patients without LC on PD (log-rank: p <0.001). After multivariate adjustment, prior gastrointestinal bleeding (HR 1.731, 95% CI, 1.635-1.834), LC (1.682, 95% CI, 1.524-1.856), alcoholism liver disease (1.536, 95% CI, 1.635-1.834), and receiving HD (1.316, 95% CI, 1.153-1.502) were independently risks for UGI bleeding in ESRD dialysis patient . Gastric ulcers were found to be the most common source of bleeding (50.3%), while bleeding resulting from a gastrojejunal ulcer was least frequent .

Conclusions: ESRD dialysis patients had a higher risk for UGI bleeding, especially those with prior gastrointestinal bleeding, LC, and alcoholism liver disease. In addition, receiving HD is a strong predictor for UGI bleeding. More attention should be paid to select dialysis modality, especially in high risk patients.

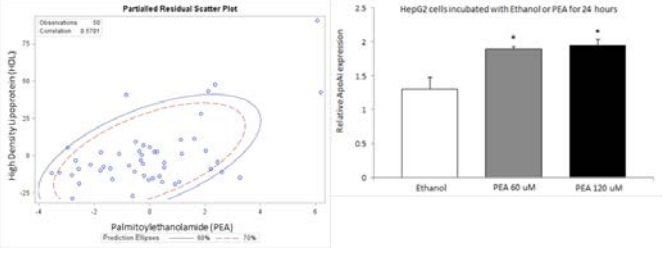
FR-PO805

Palmitoylethanolamide Is a Promising Potential Therapeutic Target for Increasing High Density Lipoprotein Cholesterol Levels Hamid Moradi,[1,2] Miki Igarashi,[1] Melissa Soohoo,[1] Elani Streja,[1] Hamid M. Said,[1,2] Moti L. Kashyap,[1,2] Daniele Piomelli,[1] Kamyar Kalantar-Zadeh.[1,2] *[1]UC Irvine; [2]VA Long Beach.*

Background: End stage renal disease (ESRD) is associated with significant increased risk of cardiovascular (CV) mortality. High density lipoprotein (HDL) deficiency and dysfunction is a major contributor to CV disease in ESRD. Strategies aimed at improving HDL level and function are crucial in improving CV outcomes. Palmitoylethanolamide (PEA) is an anti-inflammatory lipid derived mediator that activates PPARalpha nuclear transcription factor. We hypothesized that serum PEA will correlate with HDL and PEA can increase HDL via activation of apolipoproteinAI (ApoAI) expression.

Methods: Serum PEA concentration was determined in 50 patients on maintenance hemodialysis (MHD) using LC/MS technology and correlated with clinical laboratory indices including a lipid panel. Liver cells (Hepatoma cell line HepG2) were exposed to various concentrations of PEA in-vitro for 24 hours and subsequently mRNA expression of ApoAI, the major protein component of HDL, was measure using real-time PCR.

Results: Serum PEA concentrations strongly correlated with serum HDL levels in MHD patients (r=0.57, p <0.0001). PEA also correlates with total cholesterol (r=0.36, p=0.009) however not with LDL or triglycerides. In the in-vitro studies, PEA at a concentration of 60 micromolar and 120 micromolar was increased ApoAI expression significantly in HepG2 cells after 24 hours.



Conclusions: For the first time we report that serum PEA concentrations strongly correlate with serum HDL concentrations in MHD patients. Involvement of PEA in HDL production is confirmed in in-vitro studies where incubation of liver cell in PEA resulted in increased ApoA-I expression. These novel findings indicate that PEA may be a promising therapeutic target in HDL deficiency treatment associated with not just ESRD but any proatherosclerotic condition.

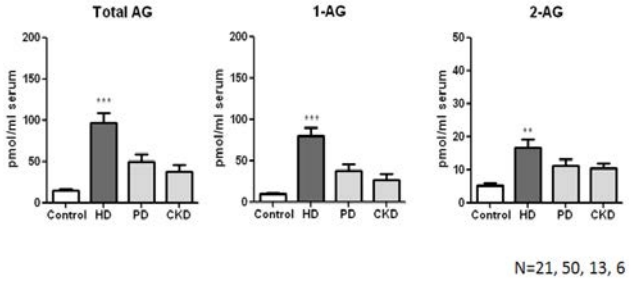
FR-PO806

Arachidonoylglycerol, a Major Activator of the Endocannabinoid System, Is Significantly Increased in Patients with Kidney Disease Hamid Moradi,[1,2] Miki Igarashi,[1] Melissa Soohoo,[1] Elani Streja,[1] Connie Rhee,[1] Hamid M. Said,[1,2] Moti L. Kashyap,[1,2] Nosratola D. Vaziri,[1] Daniele Piomelli,[1] Kamyar Kalantar-Zadeh.[1,2] *[1]UC Irvine; [2]VA Long Beach.*

Background: Chronic kidney disease (CKD) is associated with oxidative stress and inflammation. There is evidence that cannabinoid 1 receptor activation leads to increased oxidative stress and inflammation. We previously showed that 2-arachidonoylglycerol (2-AG), one of the main activators of the endocannabinoid system, is significantly increased in the kidney of animals with ischemia-reperfusion (IR) injury. We hypothesized that serum 2-AG levels will be significantly elevated in CKD patients.

Methods: Serum concentrations of AG were determined in 21 healthy controls, 50 randomly assigned age and gender matched patients on maintenance hemodialysis (MHD), 13 patients on peritoneal dialysis (PD) and 6 patients with CKD stage IV using LC/MS technology. In MHD patients, serum levels of AG were correlated with various laboratory indices.

Results: Serum levels of 1-AG and 2-AG were significantly and incrementally increased with CKD compared to healthy controls. MHD patients had the highest AG levels which positively and significantly correlated with number of treatments per week (r=0.47, p=0.008), AST/ALT (r=0.5, p=0.001), platelet count (r=0.40, p=0.008), ferritin (r=0.36, p=0.016) and negatively with HDL cholesterol (r= -0.43, p=0.04).



Conclusions: For the first time we report that serum AG concentrations are significantly increased in CKD patients. These novel findings are in line with our report on IR acute kidney injury and with a recent study which showed that in an oxidative stress setting, monoacylglycerol lipase, an enzyme responsible for AG breakdown is inhibited leading to increased levels. Moreover, the substantial increase in MHD patients is intriguing given association of MHD with increased oxidative stress, inflammation and platelet activation.

FR-PO807

Newly Launched Cellulose Tri-Acetate Membrane with Asymmetric Structure Dramatically Improves Peripheral Circulation and Hemodynamic Stability During Hemodialysis Ikuto Masakane. *Yabuki Hospital, Nephrology, Yamagata, Japan.*

Background: The most important concern about the biocompatibility of dialysis membrane is the activation of platelets and it would lead hemodynamic instability during dialysis session. The newly launched CTA with asymmetric thick structure (ATA) was produced in order to reduce stimulant property to platelets and the rapid reduction of the serum levels of small uremic solutes by thickening the membrane. We evaluated the solute removal performance and biocompatibility of ATA.

Methods: Seven chronic hemodialysis patients were enrolled to the current study. The conventional CTA was used for the first 4 months and ATA was used for the next 4 months. We evaluated the solute removal property by the clearance of urea, beta-2 microglobulin (B2MG) and removed amount of alpha-1 microglobulin (A1mG) and albumin loss in spent dialysate. The biocompatibility was evaluated by changes in WBC and platelet count, IL-6, Pentorexine-3 (PTX-3) and high sensitive CRP (hsCRP). The peripheral circulation was estimated by the Skin Perfusion Pressure (SPP) by PAD-3000® (Kaneka Medix, Osaka, Japan). Intra-dialytic hemodynamic stability was evaluated by arterial blood pressure and subjective feelings of the patients.

Results: The clearance of Urea was significantly reduced through dialysis session in both groups but the B2MG clearance was maintained only in ATA. The total removed amount of B2MG and the albumin leakage were not different between 2 groups. The removal of A1mG was significantly higher in ATA than CTA. The platelet count didn't change in ATA during dialysis session but significantly decreased in CTA. WBC counts, IL-6, PTX-3, hs CRP in both groups didn't change. The systolic blood pressure and frequency of intra-dialytic hypotension were not different in both groups whereas some of the patients felt that post-dialytic fatigue improved in ATA. SPP was maintained during dialysis session in ATA but deteriorated in CTA.

Conclusions: The new ATA membrane could reduce the activation of platelets and maintain the peripheral circulation during a dialysis sessions and the time-dependent deterioration of solute removal. The new ATA membrane may improve the QOL and prognosis of chronic dialysis patients.

FR-PO808

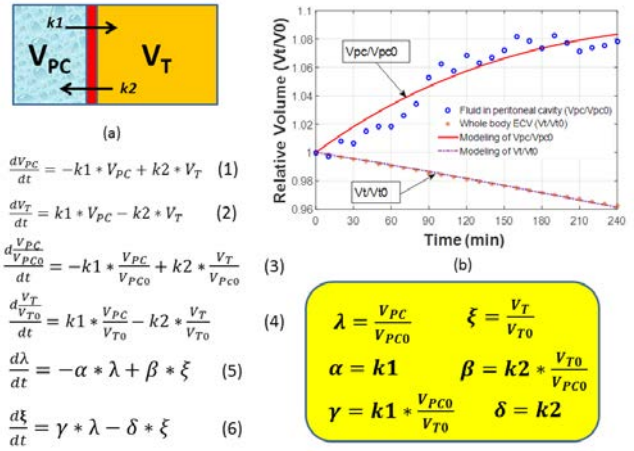
Mathematical Modeling of Fluid Transport in Peritoneal Cavity Fansan Zhu,[1] Samer R. Abbas,[1] Roxana M. Bologa,[2] Aurelita Lanto,[2] Peter Kotanko,[1,3] Nathan W. Levin.[1] *[1]Renal Research Inst, New York, NY; [2]Rogosin Inst, New York, NY; [3]Icahn School of Medicine at Moun Sinai, New York, NY.*

Background: The current standard method (peritoneal equilibration test (PET)) is used to obtain transport characteristics of the peritoneal membrane for creatinine, urea and electrolytes, but not for fluid volume. Consequently, ultrafiltration profiles are difficult to obtain because the weight difference between the inlet and outlet dialysate show only net removal during PD. The aim of this study was to investigate whether the rate of change in fluid (V_{PC}) in peritoneal cavity and body tissue fluid volume (V_T) can be simulated with a two compartment model.

Methods: Segmental bioimpedance was continuously monitored in ten PD patients to provide V_{PC} during standard PET in the clinical unit (Zhu, et al, Am J Kidney Dis, 2003). V_T was measured with whole body bioimpedance technique (Hydra 4200). A two compartment model of V_{PC} and V_T (Fig. 1(a)) was established (Eq.1-Eq.6). Two transport coefficients: k1 and k2 represent the rate of fluid shift from V_{PC} to V_T by reabsorption and from V_T to V_{PC} , driven by the glucose gradient. k1 and k2 were estimated by best fitting with the actual measurements based on the Marquardt–Levenberg algorithm .

Results: Parameter estimation was successful (residuals<0.01) in all but one patient, who experienced technical problems during the measurements. Fig. 1 (b) shows change in V_{PC} and V_T by modeling simulation in a patient. K2 correlated inversely with the initial tissue fluid volume V_{T0} (k2=-0.0002* V_{T0} +0.0024, R^2=0.46, p<0.05).

Conclusions: This model describes dynamics of fluid transport during PD treatment. K1 and k2 reflect the characteristics of peritoneal membrane in individual patient. The relationship of K2 and V_{T0} suggests that fluid status could be a factor affect in ultrafiltration,which could be helpful in clinical practice.



FR-PO809

Linagliptin Ameliorated Methylglyoxal-Induced Peritoneal Fibrosis in Mice Takuo Nagai, Shigehiro Doi, Ayumu Nakashima, Takao Masaki. *Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.*

Background: Recent studies have reported that methylglyoxal (MGO) was increased in peritoneal dialysis patients, playing an important role in the development of peritoneal fibrosis. On the other hand, linagliptin, a dipeptidyl peptiase-4 (DPP-4) inhibitor, exhibits beneficial effects in diabetes patients independent of blood glucose concentration. In this study, we examined whether linagliptin suppressed MGO-induced peritoneal fibrosis in mice.

Methods: Male C57/BL6 mice were divided into three groups: a vehicle group, an MGO injection group, or an MGO injection plus linagliptin group (n=6 per group). Peritoneal fibrosis was induced by a daily intraperitoneal injection of saline containing 40 mmol/L MGO for 21 days. Saline was given in the vehicle group. Linagliptin was administered at a dose of 10 mg/kg by oral gavage once a day.

Results: Immunohistochemical staining revealed that linagliptin suppressed the expression of α-smooth muscle actin and fibroblast-specific protein-1, the deposition of collagen 1 and collagen 3 and infiltration of macrophages (F4/80). In addition, linagliptin reduced TGF-β1 concentration in peritoneal fluid of MGO-treated mice. Peritoneal equilibration tests showed improvement of peritoneal function in mice receiving linagliptin treatment.

Conclusions: These results suggest that oral administration of linagliptin ameliorated MGO-induced peritoneal fibrosis.

Addition of Alanyl-Glutamine to Dialysis Fluid Restores Peritoneal Cellular Stress Responses – A Randomized Controlled First-in-Man Trial Andreas Vychytil,[1] Klaus Kratochwill,[1,2] Michael Boehm,[1] Rebecca Herzog,[1,2] Katharina Gruber,[1] Anton Lichtenauer,[1,2] Lilian Kuster,[1,2] Dagmar Csaicsich,[1] Andreas Gleiss,[1] Martin Bilban,[1] Seth L. Alper,[3] Christoph Aufricht.[1] *[1]Medical Univ of Vienna, Vienna, Austria; [2]Zytoprotec GmbH, Vienna, Austria; [3]Beth Israel Deaconess Med. Ctr., Harvard Medical School, MA.*

Background: Peritoneal dialysis (PD) fluid cytotoxicity and intermittent bacterial infections contribute to membrane failure and peritonitis in PD patients. Recent meta-analyses revealed no significant influence of newer biocompatible PD fluids on peritonitis rate or peritoneal membrane function, but glutamine addition to standard PD fluids has shown cytoprotective effects both *in vitro* and *in vivo*.

Methods: In this open-label randomized controlled cross-over phase I/II trial (NCT01353638), 20 stable PD patients each underwent two 4 h peritoneal equilibration tests with glucose-based PD fluids supplemented with or lacking 8 mM alanyl-glutamine dipeptide (AlaGln), and separated by a 4 week washout phase. Effects of AlaGln on peritoneal inflammation and stimulated cytokine release were also tested in a mouse model of PD-associated peritonitis.

Results: Intraperitoneal (IP) exposure to AlaGln-supplemented PD fluid increased dialysate [glutamine] more rapidly (at 2 h mean 0.55-0.71 mM, p<0.05) and increased heat shock protein expression in peritoneal effluent cells (median 2.12-3.20, p<0.05), but did not alter peritoneal ultrafiltration, small solute transport, cell counts, or biomarkers. AlaGln increased *ex vivo* LPS-stimulated TNF-α release (effect CI 60-100 pg/mL, p<0.001) and, in patients with previous peritonitis, decreased dialysate [IL-8] (effect CI 0.1-4.3, p<0.05). IP AlaGln also reduced inflammation and enhanced cytokine release in the mouse model. No adverse effects of AlaGln were noted.

Conclusions: AlaGln addition to standard PDF acutely attenuated PD-related pathomechanisms in humans and in mice. These data encourage our ongoing phase II trial testing IP AlaGln supplementation as a routine therapeutic intervention in clinical PD.

Dipeptide Alanyl-Glutamine Protects from Peritoneal Fibrosis and Attenuates IL-17 Dependent Pathways During Peritoneal Dialysis

Evelina Ferrantelli,[1] Georgios Liappas,[2] Marc Vila cuenca,[1] Marc G. Vervloet,[3] Robert H.j. Beelen,[1] Manuel Lopez-Cabrera.[2] *[1]Dept of Molecular Cell Biology and Immunology, VU Univ Medical Center, Amsterdam, Netherlands; [2]CSIC-UAM, Centro de Biología Molecular Severo Ochoa, Madrid, Spain; [3]Dept of Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.*

Background: Peritoneal dialysis (PD) is complicated by chronic inflammation and progressive peritoneal membrane damage. Alanyl-Glutamine (Ala-Gln), a stable dipeptide commonly used in parenteral nutrition, has immunomodulatory effects and improved resistance of mesothelial cells to PD fluids. Recently, IL-17 was identified as novel player in PD induced peritoneal damage. In this study we investigated if intraperitoneal Ala-Gln administration confers protection against peritoneal damage by modulating IL-17 expression in uremic rodent PD models.

Methods: Uremia was obtained by performing 5/6 nephrectomy and animals were daily instilled with PD fluid enriched or not with Ala-Gln during a period of 5 and 8 weeks respectively for rats and mice. Mice were injected weekly with recombinant IL-17 or with αIL-17. Histological analysis was carried out in parietal peritoneum. Gene expression in the parietal peritoneum biopsies was evaluated by real-time quantitative PCR. Protein levels were determined by ELISA in peritoneal effluents.

Results: Supplementation of PD fluid with Ala-Gln resulted in reduced peritoneal thickness (70.90 ±13.45 vs 16.23 ± 0.70, P<.001), aSMA expression and angiogenesis. Addition of Ala-Gln also showed attenuation of PD induced IL-17 mediated pathways, reflected by substantial reduction/normalisation of peritoneal levels of IL-17 (32.55 ±3.32 vs 7.99 ± 1.59, P<.001), TGFβ, IL-6 and ROR(γ)t. Moreover, repeated exposure of the Ala-Gln treated group to recombinant IL-17 increased peritoneal fibrosis which was however restored upon IL-17 neutralization.

Conclusions: These results suggest that intraperitoneal administration of Ala-Gln ameliorates PD induced peritoneal damage at least in part by modulating IL-17 expression. Therefore, this evidence paves into investigations whether Ala-Gln could be a potential strategy to ameliorate peritoneal deterioration during PD.

FR-PO812

JAK1/2 Inhibitor Preserves Peritoneal Membrane Function in a Non-Uremic Peritoneal Dialysis Rat Model

Tiane Dai,[1] Ying Wang,[1] Panida Ditsawanon,[2] Pornanong Aramwit,[2] Janine A. La page,[1] Sharon G. Adler.[1] *[1]Internal Medicine, LA Biomed at Harbor-UCLA Medical Center, Torrance, CA; [2]Pharmacy Practice, Chulalongkorn Univ, Bangkok, Thailand.*

Background: We previously showed JAK/STAT pathway activation in the peritoneal membrane (PM) of rats receiving PD with 4.25% Dianeal for 10 days; concomitant treatment with a JAK1/2 inhibitor (JAKi) attenuated PM inflammation, fibrosis, and hypervascularity. We also showed that the mean concentration of MCP-1 was higher in the PD fluid of patients on long-term PD (>6mos) vs new patients (<2wks), demonstrating the potential for clinical relevance (KI.2014). These experiments were performed to determine if a JAKi could prevent deterioration of peritoneal membrane function after longer-term exposure to PD fluid.

Methods: Tunneled PD catheters were placed in rats who received BID infusions of normal saline (n=3), 4.25% Dianeal (n=3), or 4.25% Dianeal + JAKi (n=3) for 12 weeks. Peritoneal equilibration testing (PET) was performed at baseline and again after 12 weeks of fluid instillation. For PET calculations, dialysate glucose was measured enzymatically at time 0 and at 90 minutes after fluid instillation. Plasma and dialysate total protein were measured at 90 minutes after dialysate instillation. D/D_0 glucose and D/P total protein were calculated as [D/D_0 glucose (at 12 wks)]; and [D/P total protein (12 weeks – Baseline)/ Baseline] for each rat. Results are expressed as mean + SD for each group.

Results: Both D/Do glucose and D/P total protein functional measurements demonstrate that JAKi protects the peritoneal membrane from the damaging effects of 4.25% Dianeal.

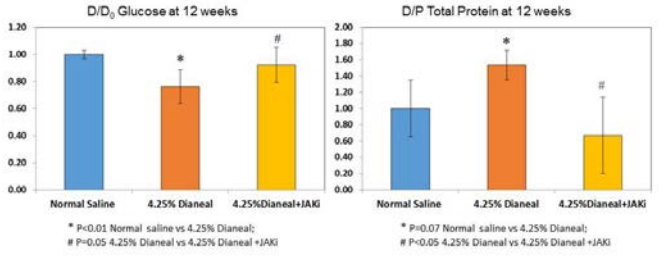

Figure 1

Conclusions: Membrane failure limits the use of PD long-term. Strategies that preserve PD function are critically needed. Together with our prior results, these studies demonstrate the capacity of JAKi to preserve rat PD membrane structure and function during PD fluid exposure.

MicroRNA Expression Profiling in Peritoneal Fibrosis

Yoshiyuki Morishita,[1] Daisuke Nagata.[2] *[1]Div of Nephrology, Dept of Integrated Medicine, Saitama Medical Center, Jichi Medical Univ, Saitama, Japan; [2]Div of Nephrology, Dept of Internal Medicine, Jichi Medical Univ, Shimotuke, Tochigi, Japan.*

Background: Peritoneal fibrosis (PF) is an intractable complication leading to peritoneal membrane failure in peritoneal dialysis (PD). The aim of this study was to identify the microRNAs (miRNAs) involved in PF.

Methods: miRNA screen was performed using microarray analysis in peritoneal tissue of PF rats induce by intraperitoneally injection of PD fluid containing methylglyoxal (MGO). The expression level of identified miRNAs of serum and drained dialysate were evaluated the association of peritoneal membrane functions measured by peritoneal equilibration test (D/P Cr and D/D0 glucose) in 33 PD patients. Furthermore, an identified miRNA inhibitor (anti-miRNA-21-5p locked nucleic acid: anti-miRNA-21-LNA) was intraperitoneally injected to PF model mice to investigate its effects for PF.

Results: The initial profiling study identified 6 miRNAs (miRNA-21-5p, miRNA-221-3p, miRNA-223-3p, miRNA-142-3p, miRNA-327 and miRNA-34a-5p) increased more than two fold and no miRNA decreased less than half in peritoneum tissue of PF rats compared with control rats. Among them, serum level of miRNA-21-5p (D/P Cr r=0.44, p=0.01; D/D0 glucose r=-0.433, p=0.01), miRNA-327(D/P Cr r=0.48, p<0.01; D/D0 glucose r=-0.50, p<0.01) and miRNA-221-3p (D/P Cr r=0.50, p<0.01; D/D0 glucose r=-0.50, p<0.01) and drained dialysate level of miRNA-221-3p (D/P Cr r=0.52, p<0.01; D/D0 glucose r=-0.46, p<0.01) and miRNA-34a-5p (D/P Cr r=0.44, p<0.01; D/D0 glucose r=-0.48, p<0.01) were significantly correlated with peritoneal membrane functions in PD patients. Anti-miRNA-21-LNA significantly inhibited miRNA-21-5p expression in peritoneum of PF mice. It also inhibited peritoneal fibrous thickening and maintained better peritoneal membrane functions. It significantly increased PPAR-α expression in peritoneum of PF mice.

Conclusions: The results of present study suggested several miRNAs involved in PF, and they may be used as the novel diagnosis biomarkers and therapeutic targets for PF.

FR-PO814

Nanoparticules of Lipids Associated with Paclitaxel as an Alternative Strategy to Block Peritoneal Fibrosis

Filipe M. Silva,[1] Rafael Pepineli,[1] Elerson Costalonga,[1] Raul Cavalcante Maranhão,[2] Irene L. Noronha.[1] *[1]Nephrology Div, Univ of Sao Paulo, Brazil; [2]Laboratory of Lipids Metabolism, Univ of Sao Paulo, Brazil.*

Background: Peritoneal fibrosis (PF) and loss of ultrafiltration represent important complications of long term peritoneal dialysis, with limited options of treatment. Advances in nanotechnology enabled drug release systems that can provide the release of an active drug in the target tissue. Nanoparticles similar to LDL were developed, linked to Paclitaxel (NanoPACL), an antiproliferative drug. NanoPACL have the ability to bind to LDL receptors present on the cell surface, particularly in immune-inflammatory sites. The aim of this study was to analyze the effect of NanoPACL administration in an experimental model of PF.

Methods: PF was induced in Wistar rats by daily IP injections of chlorhexidine gluconate (CG) at 0.1% during 15 days. Animals (n=20) were divided into 4 groups: **Control**, normal rats; **PF**, rats receiving injections of GC; **Nano**, PF rats treated with nanoparticles without Paclitaxel, via IP; **NanoPACL,** PF rats treated with NanoPACL (4mg/kg every 3 days, via IP). Euthanasia was performed on day 30. Peritoneal thickness and function, immunohistochemistry and qPCR were analyzed.

Results: NanoPACL significantly reduced peritoneal thickness, α-SMA expression and cell proliferation compared with control groups. Treatment with NanoPACL decreased TGF-β and Smad 3 mRNA expression and preserved peritoneal function characterized by preservation of UF and reduced mass transfer of glucose (MTG).

	Control	PF	Nano	NanoPACL
Peritoneal thickness (μm)	39±5	130±27*	95±10*	40±9#†
UF (mL)	4±3	-12±2*	-7±1*	5±1#†
MTG (g/Kg BW)	342±3	406±6*	393±2*	368±2*#†
α-SMA (%)	0±0	8±1*	7±1*	3±1*#
PCNA (cells/mm²)	1±0	234±32*	203±24*	28±10*#†
TGF-ß	1±0,1	5±1*	4,3±1*	1,8±1#†
Smad3	1±0,1	6±1*	6±1*	3±1#†

*p<0,05 vs Control;#p<0,05 vs PF;†p<0.05 vs Nano.

Conclusions: NanoPACL administration was effective in preventing PF and preserving peritoneal function, possibly by local effect of Paclitaxel.

Vitamin D Receptor Activator (VDRA) Attenuates Epithelial-to-Mesenchymal Transition (EMT) via Modulation of NAPDH Oxidase (NOX) Activity and Mitochondrial Dysfunction in Human Peritoneal Mesothelial Cells (HPMC) Duk-Hee Kang, Jiyeon Ko, Hyun-soo Shin, Eun sun Ryu, Hyun-yon Jung, Shina Lee, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi. *Dept of Internal Medicine, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea.*

Background: EMT is known as a key mechanism of peritoneal fibrosis in peritoneal dialysis. Oxidative stress induced by NOX and mitochondrial dysfunction is one of the mechanisms responsible for EMT. Paricalcitol, a selective VDRA, is known to exert anti-fibrotic effect organ fibrosis, however there are no studies about the role of paricalcitol on peritoneal fibrosis. We investigated whether paricalcitol imposed any effect on TGFb1-induced EMT of HPMC with an exploration of mechanism of antifibrotic effect of paricalcitol in terms of modulation of oxidative stress.

Methods: EMT was evaluated by morphological changes of HPMCs and the expressions of E-cadherin and α-smooth muscle actin. Intracellular ROS was analyzed by measuring NOX activity, H_2O_2 generation, NOX mRNA expressions with DCF-DA and MitoSox^R staining. Activation of Erk1/2, p38 MAPK, nuclear translocation of β-catenin and snail expression were assessed by western blotting and immunocytochemistry. Effect of paricalcitol on ROS generation and EMT was analyzed in HPMC exposed to TGFb1.

Results: TGFb1 (1ng/ml) induced EMT of HPMCs with an increase in ROS generation and NOX activity from 30 minutes, and mitochondrial ROS production from 6 hours. TGFb1 also increased the phosphorylation of Erk and p38 MAPK from 1hour, which was followed by nuclear translocation of β-catenin and snail up-regulation in HPMC. Paricalcitol (50nM) ameliorated TGF-β1-induced EMT in HPMC, which was associated with a decrease in both NOX- and mitochondria-mediated ROS production. TGFb1-induced EMT was partially alleviated by N-acetyl cysteine (5mM) or apocynin (100μM), which was further inhibited by an addition of rotenone (1μM) or paricalcitol.

Conclusions: One of the VDRAs, paricalcitol, ameliorated TGFb1-induced EMT of HPMCs by a decreased in ROS generation in HPMCs. Anti-oxidant effect of paricalcitol seems to be related to the direct inhibition of NOX and mitochondria-mediated ROS production.

Adenosine Monophosphate-Activated Protein Kinase (AMPK) Agonist Attenuated Epithelial-to-Mesenchymal Transition (EMT) of Mesothelium and Peritoneal Fibrosis via an Amelioration of Oxidative Stress Duk-Hee Kang,[1] Jiyeon Ko,[1] Eun sun Ryu,[1] Hyun-yon Jung,[1] Shina Lee,[1] Dong-Ryeol Ryu,[1] Seung-Jung Kim,[1] Kyu Bok Choi,[1] Sun-Hee Park,[2] Yong-Lim Kim.[2] *[1]Dept of Internal Medicine, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea; [2]Kyungpook National Univ School of Medicine, Daegu, Republic of Korea.*

Background: Phenotype transition of peritoneum has been regarded as an early mechanism of peritoneal fibrosis. Metformin, one of the AMPK agonists, has recently received a new attention due to an inhibitory effect on EMT of cancer cells. We investigated whether metformin imposed any effect on EMT of HPMC with an exploration of cellular mechanism for anti-fibrotic effect of metformin.

Methods: EMT was evaluated by morphological changes and the expressions of E-cadherin and α-SMA after stimulation of TGFb1 (1ng/ml). ROS generation was analyzed by DCF-DA, NOX activity, NOX mRNA expressions, and MitoSox^R staining. Activation of Smad2/3, MAPK, nuclear translocation of β-catenin and snail expression were also assessed. Animal model of peritoneal dialysis (PD) was established by daily infusion of 4.25% glucose-based dialysate for 8 weeks via intraperitoneal catheter. Effects of metformin (50 mg/kg/day, ip) on EMT, peritoneal thickening and an expression of markers of oxidative stress were investigated.

Results: TGFb1-induced EMT in HPMC was ameliorated by metformin. TGFb1 increased ROS generation and NOX activity from 30 min, and mitochondrial ROS production from 6 hrs. TGFb1 increased the phosphorylation of smad2/3 and MAPK, which was followed by nuclear translocation of β-catenin and snail up-regulation. Metformin ameliorated ROS production, the activation of smad2/3 and MAPK, and snail expression. In PD model, metformin decreased peritoneal thickness and EMT with an increase in ratio of reduced to oxidized glutathione and superoxide dismutase activity. Metformin also decreased the expression of nitrotyrosine in peritoneum and 8-OHdG in dialysate.

Conclusions: AMPK may play a role in preservation of peritoneal function by protecting the peritoneum from phenotype transition and fibrosis via an amelioration of oxidative stress.

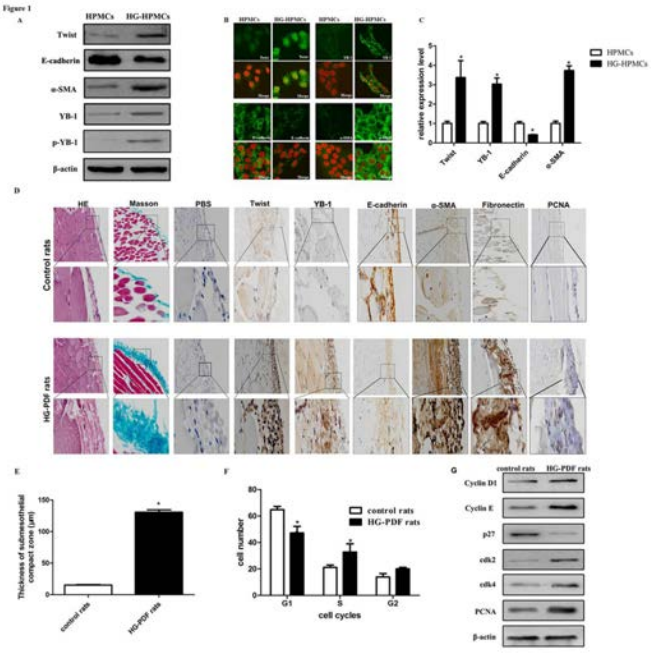
Twist Accelerates Human Peritoneal Mesothelial Cells Proliferation and Fibrosis by Regulating YB-1 Lijie He. *Dept of Nephrology, Xijing Hospital, Xi'an, China.*

Background: We have previously shown that E-box–binding transcription factor Twist is overexpressed in high glucose damage of human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis in vitro. Here, we further identify its precise function related to peritoneal membranes (PM) fibrosis.

Methods: We have previously shown that E-box–binding transcription factor Twist is overexpressed in high glucose damage of human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis in vitro. Here, we further identify its precise function related to peritoneal membranes (PM) fibrosis.

Results: Here, up-regulated expression and activation of Twist and YB-1 were found in HPMCs under extensive periods of PM fibrosis ex vivo. In immortal HPMCs and in HG-induced PD animal model, Twist and YB-1 were also up-regulated and a transformed fibroblastic phenotype of HPMCs was found stimulated by high glucose (HG, 60 mmol/L).



Evidence from chromatin immunoprecipitation and reporter assays further supported that YB-1 were transcriptionally regulated by Twist directly binding to E-box. Collectively, these data suggested that YB-1 was a major downstream target of Twist. Re-expression of Twist led to decrease HPMCs growth, induced cell cycle arrest and increase PM fibrosis. Silencing of Twist or YB-1 could promote cell cycle progress of HG-induced HPMCs growth, increasing cyclin D1/CDK2 and cyclin E/CDK4 expression and also inhibited PM fibrosis

Conclusions: Our data suggested that activation of Twist/YB-1 pathway might contribute to the growth retardation of HPMCs and the progressive PM fibrosis during PD.

The Expression of miRNA200a in Peritoneal Dialysis Associated Peritoneal Fibrosis Xin Wei. *Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.*

Background: Peritoneal fibrosis (PF) is an almost invariable consequence of peritoneal dialysis (PD), which is an established alternative for the replacement therapy of end-stage renal disease. We know that miR-200a belong to miR-200 family,which is closely related to a variety of fibrotic diseases.However, the role of miR-200a in peritoneal fibrosis is largely unknown.

Methods: The peritoneal fibrosis mouse model associated with PD was established by intraperitoneal injection of lipopolysaccharide + 4.25% peritoneal dialysate. The expression of miRNA was detected by microarray. The expression of miRNA profiles between fibrotic and normal peritoneal tissues was compared (n=3 in each group). The differentially expressed miRNA (miR-200a) was validated by real-time PCR in lager sample size cohorts (n=15). The expressions of miR-200a were also detected in the epithelial-mesenchymal transition (EMT) process of peritoneal mesothelium cells.

Results: In mice model of PD, peritoneal tissue was markedly thickened and with a massive extracellular matrix accumulation. By miRNA microarray analysis, miR-200a was significantly down regulated (3.31 folds change, $P<0.05$) infibrotic peritoneal tissues. The down-regulated expression level of miR-200a was also validated by real-time PCR in larger cohorts ($P<0.05$). Then, the expression level of miR-200a was detected in the EMT process of human peritoneal mesothelium cells. During the process of TGF-β1 induced EMT, miR-200a was significantly down-regulated compared with the control ($P<0.05$)

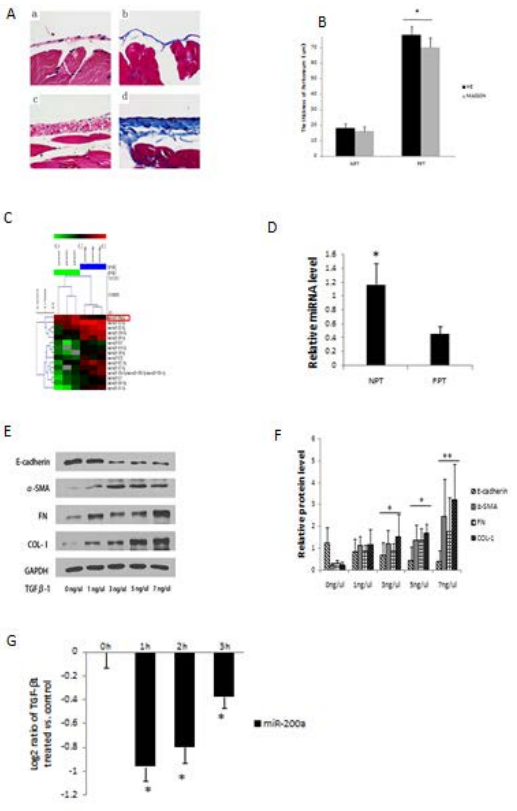

Fig.1. A,B: peritoneal fibrosis in a mouse model of PD. C,D: peritoneal fibrosis index expression. E, F: EMT index expression during the EMT process of human peritoneal mesothelium cells.; G:miR-200a expression level down-regulated during the EMT process .. NPT: normal peritoneal tissue, FPT: fibrotic peritoneal tissue,* P<0.05, ** P<0.01.

Conclusions: Down-regulated expression of miR-200a was observed both during peritoneal fibrosis and TGF-β1 induced EMT in vivo and in vitro, suggesting that miR-200a may be involved in the peritoneum fibrosis by regulating the target genes of EMT.

FR-PO819

Peritonitis Induces Native and EDA$^+$ Fibronectin Synthesis in Human Peritoneal Mesothelial Cells Through PI3K and MAPK Activation

Susan Yung, Na Li, Mel Chau, Mandy K. M. Kam, Daniel Tak Mao Chan. *Dept of Medicine, The Univ of Hong Kong, Hong Kong.*

Background: Peritonitis is a severe complication of peritoneal dialysis (PD), which could lead to progressive structural and functional deterioration of the peritoneum and PD failure. EDA$^+$ fibronectin (FN) is induced during disease states, but its expression in PD associated peritonitis has not been investigated. We examined peritoneal expression of native and EDA$^+$FN in an experimental model of peritonitis and their association with mesothelial epithelial-to mesenchymal transition.

Methods: Male C57BL/6 mice were challenged with PBS or lipopolysaccharide (LPS, 500mg) by intraperitoneal injection for 2, 3 and 6 times (n=6), after which time the parietal peritoneum was excised for further studies. Confluent, growth arrested human peritoneal mesothelial cells (HPMC) were stimulated with spent peritonitis PD fluid, LPS, or exogenous TGF-β1 or CTGF (growth factors that are increased during peritonitis) either alone or in combination, for periods up to 72h to investigate their effect on cell morphology, and FN, collagen and SNAIL synthesis.

Results: Mice exposed to six, but not fewer, challenges of LPS exhibited mesothelial denudation, influx of infiltrating cells and substantial submesothelial thickening attributed to increased collagen and native and EDA$^+$ FN deposition. Peritonitis PD fluid induced phenotypic changes, and SNAIL, collagen I, and native and EDA$^+$ FN synthesis in HPMC. Exogenous TGF-β1, but not CTGF, significantly increased native and EDA$^+$ FN by 4.3-fold and 6.2-fold respectively (P<0.05 for both). Cells co-stimulated with TGF-β1 and CTGF showed synergistic increase of native and EDA$^+$ FN. This was mediated in part through PI3K, ERK and p38 MAPK activation. TGF-β1 and CTGF neutralizing antibody significantly decreased native and EDA$^+$ FN synthesis, but had no effect on collagen I or SNAIL expression in HPMC.

Conclusions: Our data demonstrated that peritonitis, especially when recurrent, induced progressive peritoneal deposition of collagen, and native and EDA$^+$FN. TGF-β1 and CTGF synergistically induced native and EDA$^+$ FN synthesis in HPMC, and play important roles in peritoneal fibrosis induced by bacterial peritonitis.

Effects of Astragaloside IV against the TGF-β-Induced Epithelial-to-Mesenchymal Transition in Peritoneal Mesothelial Cells by Promoting Smad 7 Expression

Lu Zhang,[1,2] Zhenghong Li,[2] Weiming He,[2] Lingdong Xu,[2] Jing Wang,[3] Jun Shi,[1] Meixiao Sheng.[1,2] *[1]the First Clinical Medical College, Nanjing Univ of Chinese Medicine, Nanjing, Jiangsu Province, China; [2]Renal Div, Jiangsu Province Hospital of Chinese Medicine, Nanjing, Jiangsu Province, China; [3]Jiangsu Province Academy of Traditional Chinese Medicine, Nanjing, Jiangsu Province, China.*

Background: To investigate the effect of Astragaloside IV (AS-IV) on the regulation of the TGF-β1 Smad signaling pathway in mesothelial cells with an epithelial-to-mesenchymal transition (EMT).

Methods: EMT of human peritoneal mesothelial cells (HMrSV5) was induced using 2 ng/ml TGF-β1. Cells were randomly divided into a vehicle group, a vehicle group with AS-IV, a TGF-β1 treated group, and a TGF-β1 treated group receiving varied doses of AS-IV or NAC. Real-time quantitative PCR and western blot were used to detect the expression of genes and proteins associated with the TGF-β1/Smad signaling pathway and EMT. DCFH-DA was used to detect the generation of ROS in HMrSV5 cells, and a transwell migration assay was used to verify the capacity of AS-IV to inhibit EMT in HMrSV5 cells. Lentiviruseswere used as carriers for theoverexpression or knockdown of the Smad7 gene.

Results: Expression levels of E-cadherin (epithelial marker) was decreased and vimentin, α-SMA (EMT markers) and collagen I (extracellular matrix protein) phospho-Smad2/3, Snail1 and Snail2 was increased significantly in the TGF-β1-treated HMrSV5 cells. AS-IV was associated with downregulated expression of vimentin and phospho-Smad2/3 in a dose-dependent manner, while the expression of Smad7 increased. Silenced or forced expression of Smad7 verified its role in the inhibitory effect of AS-IV on TGF-β1-induced EMT in HMrSV5 cells.

Conclusions: AS-IV effectively promotes the upregulation of Smad7 in the TGF-β1/Smad signaling pathway during the EMT of HMrSV5 cells, indicating its potential therapeutic effect for the control of PF.

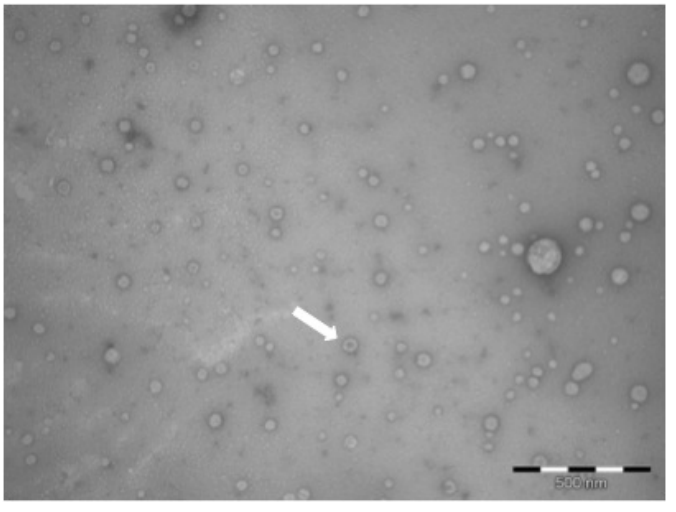
Extracellular Vesicles in Peritoneal Effluent

Deirisa Lopes Barreto,[1] Anita N. Böing,[2] Rienk Nieuwland,[2] Anita Grootemaat,[2] Raymond T. Krediet.[1] *[1]Nephrology, AMC-UvA, Netherlands; [2]Clinical Chemistry, .*

Background: Continuous and long-term exposure to peritoneal dialysis (PD) solutions induces constant low-grade inflammation and remodeling of peritoneal membrane morphology. Although the biochemical composition of peritoneal effluent offers the opportunity to explore the peritoneal membrane status in a simple and non-invasive manner, to date no clinically useful effluent biomarker has been identified that reflects the peritoneal membrane integrity sufficiently. As human body fluids contain extracellular vesicles (EVs), which are now believed to provide novel biomarkers for diseases, we investigated the presence of EVs in peritoneal effluent.

Methods: Peritoneal effluent of a short-term PD patient was collected from a regular dialysis dwell. After centrifugation, aliquots of cell-free effluent were frozen in liquid nitrogen and stored at -80°C until analysis. EVs were isolated by size exclusion chromatography. Thereafter, transmission electron microscopy (TEM) and flow cytometry (comprising markers for epithelial and mesothelial cells, leucocytes, platelets and erythrocytes) were used to detect the presence of single EVs.

Results: EVs and liposomes were identified by TEM and flow cytometry. EVs exhibited their characteristic cup shape. The majority of EVs had a mean diameter <100nm, and were present in similar amounts as in human plasma. Most EVs originate from epithelial and mesothelial cells. Moreover, EVs stained positive for leucocyte antigens, mesothelin and cancer antigen 125.



Conclusions: This is the first study to demonstrate the presence of EVs in human peritoneal effluent. Furthermore, the cellular origin of most peritoneal EVs is established.

We postulate that the presence and composition of such EVs in peritoneal effluent will closely mirror the peritoneal membrane morphology. Future studies will be necessary to investigate the clinical relevance for the detection of peritoneal membrane damage and potential use of these peritoneal EVs in PD patient care.

FR-PO822

miR-200a Negatively Regulates TGF-β1-Induced Peritoneal Mesothelial Cell Epithelial-Mesenchymel Transition by Targeting ZEB1 and ZEB2 Expression Xin Wei, Guojun Hao, Qinkai Chen. *Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.*

Background: Peritoneal fibrosis (PF) is an almost invariable consequence of peritoneal dialysis (PD), which is an established alternative for the replacement therapy of end-stage renal disease. In our previous study, we found that the expression level of miR-200a were down-regulated in fibrotic peritoneum and the epithelial-mesenchymal transition (EMT) process of peritoneal mesothelial cell.However, the role of miR-200a in EMT of peritoneal mesothelial cell and peritoneal fibrosis is largely unknown.

Methods: Human peritoneal mesothelial cell line (HMrSV5) was cultured in the presence or absence of TGF-β1. The protein expression levels of EMT index and E-box-binding homeobox (ZEB) 1/2 were determined by western blot. The level of miR-200a was determined by real-time PCR. miR-200a mimic or inhibitor and it negative control RNA,were transfected into HMrSV5 cells using Liptofectamine 2000.

Results: We found that miR-200a mimic can attenuated TGF-β1 induced peritoneal mesothelial cell EMT and synthesis of extracellular matrix. It was also demonstrated that the miR-200a was responsible for protecting peritoneal mesothelial cells from mesenchymal transition by targeting suppression of ZEB1/2.

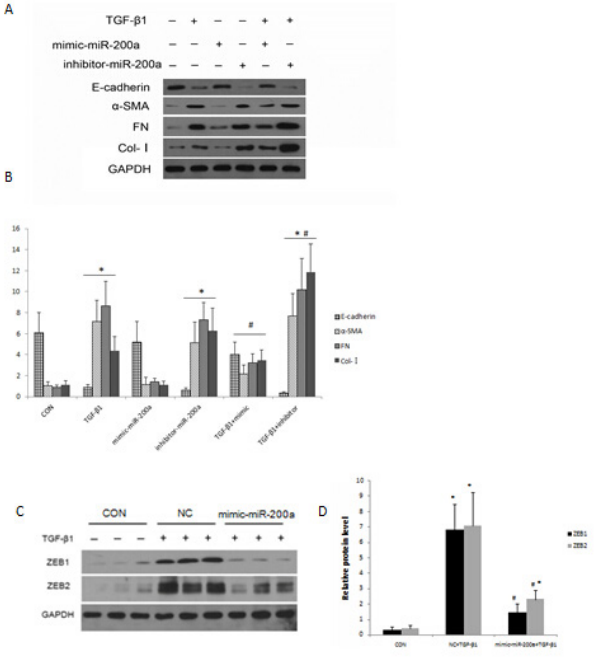


Fig. 1 A-B: EMT index expression after transfection of miR-200a mimic or inhibitor;C-D: ZEB1/2 expression after transfection of miR-200a mimic. * P<0.05, # P<0.01.

Conclusions: The results suggested that miR-200a may not only be a useful biomarker of EMT in ovarian cancer, but also of potential therapeutic value in peritoneal fibrosis.

Funding: Government Support - Non-U.S.

FR-PO823

Identification and Functional Characterization of Human Peritoneal Fibroblast Subsets According to the Expression of CD90/Thy-1 Edyta Kawka,[1] Andras Rudolf,[2] Maria Bartosova,[3] Rusan Catar,[1] Janusz Witowski,[2] Duska Dragun,[1] Achim Joerres,[1] Claus P. Schmitt.[3] *[1]Dept of Nephrology and Medical Intensive Care, Charité-Universitätsmedizin Berlin, Berlin, Germany; [2]Depts of Pathophysiology and Clinical Immunology, Poznan Univ of Medical Sciences, Poznan, Poland; [3]Center for Pediatric and Adolescent Medicine, Universitätsklinikum Heidelberg, Heidelberg, Germany.*

Background: The exact origin of myofibroblasts in PD-associated peritoneal fibrosis is unknown. Lineage tracing studies suggest that resident submesothelial fibroblasts may be their major precursors. Here, we set out to identify HPFB subsets in human peritoneum and examined co-expression of CD90/Thy-1 with markers of the myofibroblastic phenotype.

Methods: HPFB were isolated from omentum, purified and then separated (MACS) into CD90/Thy-1$^+$ and CD90/Thy-1$^-$ populations for assessment of myofibroblastic markers: qPCR, immunofluorescence, and ELISAs. Moreover, the presence of FSP-1$^+$ and CD90/Thy-1$^+$ fibroblasts was studied by immunofluorescence in peritoneal biopsies of 12 PD, 5 uremic patients, and 8 healthy controls.

Results: Cells positive for FSP-1 or CD90/Thy-1 were absent in healthy controls, but were detectable in uremic and PD patients. In those, the majority (>95%) of FSP-1$^+$ HPFB were also CD90/Thy-1$^+$. In vitro studies showed that CD90/Thy-1$^+$ HPFB had a 1.2-fold higher proliferation rate (MTT assay; n=12, p<0.05) than CD90/Thy-1$^-$. Expression of myofibroblastic markers in CD90/Thy-1$^+$ cells was significantly higher with α-SMA, collagen-1 and TGF-β1 being increased (2.5-, 1.6- and 1.8-fold, respectively; n=13, p<0.05). Furthermore, CD90/Thy-1$^+$ HPFB revealed increased contractile properties as reflected by 1.2-fold greater reduction in collagen gel contraction assays (n=3).

Conclusions: The vast majority of FSP-1$^+$HPFB detected in the peritoneum of uremic and PD patients expressed CD90/Thy-1. In contrast, this phenotype was not detected in normal peritoneum. In vitro studies demonstrated increased expression of myofibroblastic markers in CD90/Thy-1$^+$ HPFB. These cells may thus contribute to peritoneal fibrosis which often develops in patients during chronic PD.

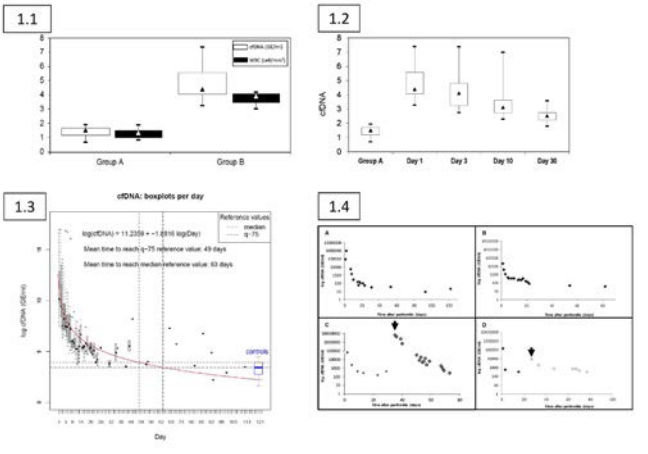
FR-PO824

Innovative Index to Follow the Peritoneal Infections and for Monitoring the Recovery Process After Pertionitis Grazia Maria Virzì, Sabrina Milan manani, Alessandra Brocca, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. *Nephrology, San Bortolo Hospital-IRRIV.*

Background: Cell-free DNA is present in the peritoneal effluent of stable PD patients, but there is no data on cfDNA in case of peritonitis. We investigated the variation of peritoneal cfDNA (pcfDNA) levels in PD-related peritonitis.

Methods: We enrolled 53 PD patients: 30 without any history of systemic inflammation and peritonitis in the last 3 months (groupA) and 23 with acute peritonitis (groupB). PcfDNA were quantified i by Real-Time PCR. Peritoneal samples on day 1-3-10-30 and until the 120th from the start of peritonitis were collected for WBC counts and pcfDNA evaluation in group B.

Results: Quantitative analysis of pcfDNA showed significantly higher levels in groupB compared with groupA (p<0.01), similarly as WBC. PcfDNA showed significantly higher levels in groupB on day1-3-10 and 30 compared with groupA (p<0.05). A significant positive correlation was observed between pcfDNA level and WBC on day1 (rho=0.89) and day3 (rho=0.5)(both p<0.05). No statistically significant correlation was observed on day10 and 30. In groupB, pcfDNA tends to progressively decrease. From this decreasing curve, we estimated that 49 days are necessary to reach the value of 51 GE/ml (75percentile in groupA) and 63 days to reach 31 GE/ml (median). We observed a new rapid increase of cfDNA level (consistent with WBC) in 5 relapsing patients, at the first day of relapsing peritonitis.



Conclusions: in conclusion, pcfDNA increased in peritoneal effluent in PD-realated peritonitis and tended to progressively decrease in relation with membrane repair process. Peritoneal cfDNA could be a new method to determine acute damage and an inverse index of repair process. PcfDNA could help to evaluate functional and structural integrity of peritoneal membrane and to follow the evolution of infections during peritonitis.

FR-PO825

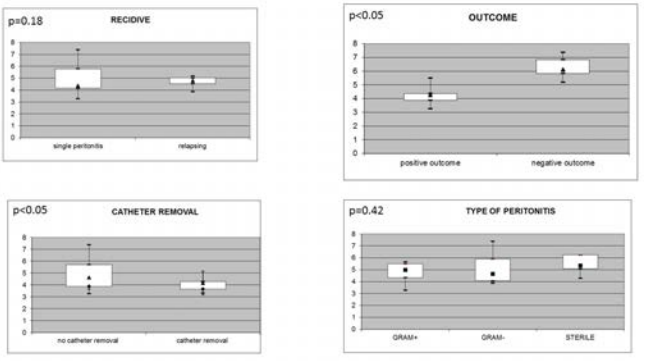
The Role of Cell-Free DNA for Managment in PD-Related Peritonitis Grazia Maria Virzì, Sabrina Milan manani, Alessandra Brocca, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. *Nephrology, IRRIV-St Bortolo.*

Background: Peritonitis and exit site infections are the major complications of PD and remains the major cause of switch from HD. In this study, we investigated the role of peritoneal cell-free DNA (cfDNA) and its association with peritonitis.

Methods: We enrolled 23 PD patients with peritonitis and without any history of systemic inflammation (14 male, mean age: 68±16yrs). cfDNA were extracted and quantified in peritoneal effluent by Real Time PCR for β-globin gene.

Results: All patients were treated and clinically recovered from peritonitis in 13.5±5.4days.18/23 patients had a first episode of peritonitis and responded to first-line antibiotics (65% Gram+, 22% Gram- and 13% sterile), whereas 5/23 had a relapsing episode of peritonitis (responded to other course of intra-peritoneal antibiotics). There

was no difference in cfDNA levels between Gram+/Gram-peritonitis; patients with single episode and relapsing peritonitis, but there was a significantly difference in cfDNA between PD patients with positive and negative outcomes (n=4), defined as death ($p<0.05$). CfDNA showed significantly higher levels in 3 patients required catheter removal($p<0.05$).There was no difference in cfDNA levels between PD patients with a negative history of previous peritonitis (n=3) and PD patients with a positive history (n=20)(p=0.48). there was no statistically significant correlation between cfDNA and number of previous peritonitis (rho=0.13, p=0.55).



Conclusions: This pilot study provided substantial basis for further investigations of molecular mechanisms of peritoneal injury and potential clinical application of cfDNA. cfDNA could provide some additional information about patient's outcome and management. These results can be considered hypothesis generating, and stimulate further exploration of a prognostic and predictive role of cfDNA in PD-related peritonitis.

FR-PO826

Epimorphin Expressions in Mice Model of Peritoneal Fibrosis

Muneharu Yamada, Takashi Oda, Shuuhei Komatsu, Taito Oshima, Tadasu Kojima, Yasuyo Sudo, Tomohiro Tomiyasu, Noriko Yoshikawa, Masahru Yoshida. *Nephrology, Hachioji Medical Center of Tokyo Medical Univ, Hachioji, Tokyo, Japan.*

Background: Long-term peritoneal dialysis induces peritoneal fibrosis in submesothelial areas. Epimorphin is a mesenchymal protein that regulates epithelial morphogenesis through epithelial-mesenchymal interactions, has recently attracted attention as an important modulator of tissue repair. We previously reported that epimorohin was involved in the repair of fibrosis in mice (*Lab Invest 2010)*. In this study, we evaluated the epimorphin expressions in the peritoneal fibrosis mice model.

Methods: Peritoneal fibrosis was induced by the injection of 0.1% chlorhexidine gluconate in 15% ethanol and 85% normal saline (CG-injected mice) into peritoneal cavity of 10 week-old male C57/Bl6 mice every other day. Control mice received intraperitoneal injection of normal saline. The mice were sacrificed 3 weeks after the first CG injection and peritoneal tissues were dissected out. Morphologic peritoneal changes were assessed by Masson's Trichrome staining. Epimorphin expressions were assessed by immunohistochemically and real-time RT-PCR.

Results: In CG-injected mice, the marked thickening of the submesothelial compact zone was shown in Masson's trichrome staining. IF staining for epimorphin was positive in the submethothelial area corresponding to the fibrotic area. Epimorphin staining was significantly stronger than that in control mice. Such an increase in epimorphin expression was confirmed by and by real-time RT-PCR (n=5, $p<0.05$ vs control).

Conclusions: These findings suggest that epimorphin expression may have pivotal role in the repair of peritoneal fibrosis similar to that of UUO release model in mice as reported previously.

FR-PO827

Peritoneal Mesothelial Cells (PMCs) Injury Induced by Neutral Peritoneal Dialysis Solution (NPDS) and Its Amelioration by Molecular Hydrogen (H_2)

Wan-jun Zhu,[1,2] Kimio Watanabe,[1] Hiroyuki Terawaki,[1] Yoshimitsu Hayashi,[1] Naoki Nakanishi,[3] Shigeru Kabayama,[2] Masaaki Nakayama.[1] *[1]Dept of Kidney and Hypertension, Medical School, Fukushima Medical Univ, Fukushima, Japan; [2]Medical Device, Nihon Trim Co. Ltd, Osaka, Japan; [3]Business Strategy & Management, Nihon Trim Co. Ltd, Osaka, Japan.*

Background: PMCs play pivotal roles in suppression of peritoneal fibrosis, adhesion, and bacterial infection in PD therapy. It is reported that histological changes of peritoneum and incidence of encapsulating peritoneal sclerosis, have been decreased by NPDS intruduction. However, meta-analysis did not show superiority of NPDS in incidence of bacterial peritonitis, suggesting bio-incompatibility of current NPDS. H_2 has anti-oxidative effects in biological way, and its clinical application has been studied. The present study aims to examine PMC injury by NPDF, and its ameliorating effect of H_2.

Methods: Male SD rats (n=24) were divided into three groups: control (Con), 2.5% glucose lactate-based NPDS (PD), and the same NPDS with dissolved H_2 (400 ppb) (HPD). The latter two groups were given NPDS or H2-NPDS intraperitoneally for 10-day 20 mL once a day. Peritoneal tissues were subjected to morphological analysis including immunohistochemistry (cytokeratin, vimentin, proliferation; Ki67, and apoptosis; M30 cytodeath), and PMCs obtained to gene analysis by real time PCR, and microarray assay.

Results: The collagen thickness increased in PD and HPD, however, there were significant changes in stainings of vimentin, M30 cytodeath, and Ki67 in PD as compared to Con, while no change in HPD. In gene cluster analysis, there were changes by 8.7% in whole gene expression between PD and Con, and 3.7% changes between PD and HPD. In PCR, no difference was found in Epithelial-Mesenchymal Transition (Snail, TGF-β, aSMA) among the groups, while wound healing (MMP9, CTGF, Fibronectin, FAK), cytokines (IL1b, TNFa,NFkb) were decreased in PD as compared to Con, but no changes in HPD.

Conclusions: The current lactate-based NPDS may disturb wound healing and local immunity of PMCs, and H_2 dissolved dialysate correct them. H_2 could increase biocompatibility of PDS in preserving physiological function of PMCs in PD therapy.

FR-PO828

Bicarbonate-Buffered Peritoneal Dialysis Solution Suppresses Lactate-Induced Apoptosis via Monocarboxylate Transporter-1 in Human Peritoneal Mesothelial Cells

Akihiro Kuma, Tetsu Miyamoto, Ryota Serino, Yumi Furuno, Yoko Fujimoto, Hiromichi Ueno, Yutaka Otsuji, Masahito Tamura. *Dept of Nephrology, Univ of Occupational and Environmental Health, Kitakyushu, Japan.*

Background: Long-term peritoneal dialysis is associated with functional and structural alterations of the peritoneal membrane. Lactate-buffered peritoneal dialysis fluid (L-PDF) has impaired biocompatibility due to the presence of supra-physiological levels of lactate. Although bicarbonate-buffered PDF (B-PDF) has been developed, its biocompatibility remains unclear. Here, we investigated the effects of L- or B-PDF on cell viability and apoptosis in cultured human peritoneal mesothelial cells (HPMCs), focusing on monocarboxylate transporters (MCT).

Methods: HPMCswere cultured in mediums containing 10% fetal bovine serum and L-PDF with 1.5% glucose (L1) or 2.5% glucose (L2), B-PDF with 1.5% glucose (B1) or 2.5% glucose (B2), or no PDF (control). Cell viability and apoptosis were measured with the WST-1 and TUNEL assays, respectively. The roles of MCT-1 and -4 on lactate-induced apoptosis were evaluated by siRNA transfection for MCT-1 and -4.

Results: Cell viability was significantly decreased in cells incubated with L1 (12±2%, control=100%) and L2 (2±1%), compared with B1 (74±2%) and B2 (72±1%) after 72 h incubation. Apoptotic cells were also increased in L1 (69±16%), L2 (73±8%) compared with B1 (3±0%) and B2 (4±1%). MCT-1 and -4 protein and mRNA expression levels, examined by Western blotting and real-time-PCR, respectively, were similar in all cells. Protein expression levels of MCT-1 and -4 were almost completely diminished after transfection of siRNAs for MCT-1 and -4, respectively. MCT-1 siRNA increased the levels of cell viability by 3.2–3.7-fold and decreased the amount of apoptotic cells from 64±8% to 47±4% in cells treated with L1 for 72 h. Interestingly, MCT-4 siRNA had no effect on cell viability and apoptosis.

Conclusions: Our results showed that L-PDF induced apoptosis by importing lactate via MCT-1 in HPMCs, and suggest that B-PDF improved biocompatibility by inhibiting mesothelial cell apoptosis.

FR-PO829

MiRNA-143/145 Gene Cluster Enhances Cell Deformation and Fibrosis of Human Peritoneal Mesothelial Cells via Modulating TPM4

Lijie He, Shiren Sun. *Dept of Nephrology, Xijing Hospital, Xi'an, Shaanxi, China.*

Background: In this study, we work for the function and mechanism of miR-143/145 gene cluster in human peritoneal mesothelial cells (HPMC), who were as possible triggers for peritoneal membrane fibrosis.

Methods: To investigate if miR-143/145 gene cluster could promote PM fibrosis, all these immortal HPMCs were characterized by fibrosis related markers and tested the expression of miRNA-143/145 cluster and tropomyosin4 (TPM4) by real time PCR or Western blot. We also used PD dialysis rat model to observe the response of PM to miR-143/145 gene cluster and their possible target.

Results: Here, we found that miR-143/145 gene cluster, which are examined to be highly expressed in HG-induced HPMCs (HG, 60 mmol/L) and in PD animal model. TPM4 were found significantly lower expression in HG-induced HPMCs. So our study showed that high glucose from PD fluid could promote the expression of miR-143/145 of HPMCs and reduce the expression of TPM4, compared with normal glucose-cultured HPMCs . Reporter assays further supported that TPM4 were post-transcriptionally regulated together by miR-143/145 gene cluster. Collectively, these data suggested that TPM4 was a downstream target of miR-143/145 gene cluster. Re-expression of miR-143/145 gene cluster by miR-143 or miR-145 mimic led to cell deformation, and reduced cell adhesion, following the down-regulating expression of TPM4 and E-cadherin, but up-regulating expression of α-SMA, CTGF, collagens and fibronectin which might increase PM fibrosis. Depletion of miR-143/145 cluster in HG-induced HPMCs enhanced cell adhesion, marking by up-regulating E-cadherin and TPM4 but down-regulating α-SMA, CTGF, collagens and fibronectin in vitro. Mechanistically, miR-143/145 gene cluster were characterized to target the messenger RNA TPM4 to contribute to the cell adhesion, deformation and fibrosis.

Conclusions: Our data suggested that miR-143/145-TPM4 pathway might contribute to the cell deformation of HPMCs and the progressive PM fibrosis during PD.

Mitochondrial DNA Copy Number Is Associated with Peritoneal Dialysis Failure in Younger and Metabolically Healthier Peritoneal Dialysis Patients

Jae Eun Um,[1] Jong Hyun Jhee,[2] Kyoung Sook Park,[2] Chang-Yun Yoon,[2] Mi Jung Lee,[2] Jung Tak Park,[2] Shin-Wook Kang,[1,2] Tae-Hyun Yoo.[1,2] *[1]Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; [2]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Insulin resistance and inflammation are known to be closely related to adverse outcomes in peritoneal dialysis (PD) patients. Recently, mitochondrial function has been reported to play a key role in glucose metabolism as well as systemic inflammation in various populations. However, the clinical consequences of mitochondrial function in PD patients are not well known. Therefore, this study was aimed to investigate the relationship of mitochondrial DNA (mtDNA) copy number and clinical outcome in PD patients.

Methods: A total of 120 prevalent PD patients were recruited. mtDNA copy number was counted by a PCR based method. Primary outcome was PD catheter removal due to ultrafiltration failure. Metabolic syndrome was defined using the Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria. Cox proportional hazard analysis was performed to determine the independent association of mtDNA copy number with primary outcome.

Results: The mean age was 52.3 years and 52 patients (42.5%) were male. The mean mtDNA copy number was 29.1±14.9. During a mean follow-up duration of 59.4±39.3 months, primary outcome was observed in 54 patients (45.0%). There were no significant differences in baseline characteristics between non-PD failure and PD failure group except for serum adiponectin levels (20.5±7.3 vs. 17.5±7.3 mg/mL, P=0.028). mtDNA copy number was not significantly associated with PD failure in multivariate Cox analysis [hazard ratio (HR)=0.995, 95% confidence interval (CI)=0.976-1.015, P=0.634]. However, a subgroup analysis revealed that mtDNA copy number was an independent predictor of PD failure in patients younger than 55 years without metabolic syndrome (HR=0.819, 95% CI=0.692-0.970, P=0.020) after adjustment for confounding factors.

Conclusions: mtDNA copy number may be associated with ultrafiltration failure in younger and metabolically healthier patients treated with PD.

FR-PO831

IL-6 Induces VEGF Production by Human Peritoneal Mesothelial Cells During Peritonitis Through SP4-Mediated Trans-Signaling with sIL-6R

Rusan Catar,[1] Janusz Witowski,[1,2] Nan Zhu,[1] Christian Luecht,[1] Andras Rudolf,[2] Duska Dragun,[1] Achim Joerres.[1] *[1]Nephrology and Medical Intensive Care, Charité-Universitätsmedizin Berlin, Berlin, Germany; [2]Pathophysiology, Poznan Univ of Medical Sciences, Poznan, Poland.*

Background: Vascular endothelial growth factor (VEGF) has been implicated in peritoneal angiogenesis and membrane remodelling in peritoneal dialysis (PD). Human peritoneal mesothelial cells (HPMC) have been identified as a major source of VEGF in the peritoneum. However, the exact mechanism of VEGF induction in HPMC is unclear. Since IL-6 concentrations in the drained dialysate correlate with VEGF levels, the link between the two has been suggested. While HPMC do not bear classical IL-6 receptor, they can respond to IL-6 trans-signalling that involves soluble IL-6 receptor (sIL-6R). Here, we have examined whether this mechanism can underlie VEGF synthesis by HPMC.

Methods: HPMC were isolated from normal omentum. Dialysate effluent was obtained from stable PD patients and during peritonitis. VEGF mRNA and protein levels were measured by RT-qPCR and ELISA, respectively. The involvement of transcriptional factors was assessed by EMSA, transient transfections with VEGF promoter constructs, and siRNA silencing.

Results: IL-6 and sIL-6R alone had no effect on VEGF release by HPMC . However, the exposure to IL-6+sIL-6R resulted in a time- and dose-dependent induction of VEGF mRNA and protein. The combination of IL-6+sIL-6R activated the VEGF promoter region that contained high affinity binding sites for the transcription factor SP4. Specific mutation of the SP4 binding site eliminated VEGF promoter activation. In turn, the induction of SP4 was controlled by STAT3. Exposure of HPMC to dialysate effluent obtained during acute peritonitis and containing increased levels of IL-6 and sIL-6R resulted in a dose-dependent VEGF induction. This effect was significantly attenuated in cells treated with siRNAs for either SP4 or STAT3.

Conclusions: Dialysate IL-6 and sIL-6R act through the trans-signalling pathway controlled by the STAT3-SP4 axis to up-regulate mesothelial VEGF production during peritonitis.

FR-PO832

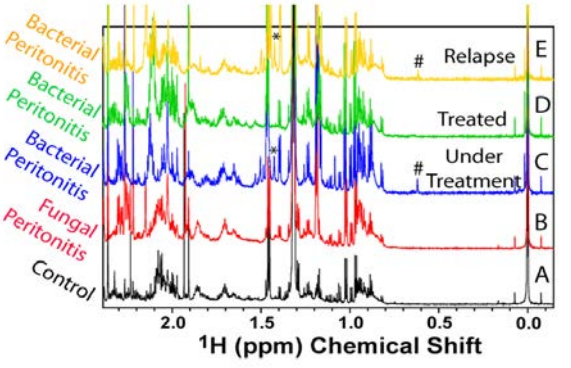
^{1}H NMR Based Metabolome Can Predict Relapsing Peritonitis and Differentiate Bacterial and Fungal Peritonitis as Well

Narayan Prasad,[1] Raj K. Sharma,[1] Amit Gupta,[1] Dinesh Kumar.[2] *[1]Nephrology and Renal Transplantation, SGPGIMS, Lucknow, UP, India; [2]CBMR.*

Background: Conventional culture methods for microbes are inherently slow and inefficient.Treatment of bacterial(BP) and fungal peritonitis(FP) are different and quick differentiation is needed. Presently, there is no biomarker to predict relapsing peritonitis(RP). Bacteria and fungus may have different metabolome as one is prokaryotic and other eukaryotic.

Methods: Five unused PD fluid, 13 effluent from normal PD and 45 effluents from 15 patients(at baseline,1 week and 2 weeks of therapy) with BP including 3 who relapsed and 3 FP were included. Half of each was subjected to total and differential WBC count and culture; and half was frozen at -80° C for NMR analysis. BP and FP was diagnosed based on identification of organism. RP was defined as per standard definition. High Resolution NMR spectra were recorded at 298 K on a Bruker Avance III 800 MHz spectrometer. Standard 1D 1H NMR spectra were acquired using the Carr–Purcell–Meiboom–Gill (CPMG) pulse sequence.To confirm the assignment of marker peak, two-dimensional (2D) 1H-1H TOCSY and 1H-13C HSQC spectra were also acquired.

Results: Five unused and 13 normal PD effluents after 6 hours of dwell did not show any marker peak at NMR spectra at 0.67 ppm while 15 cases of BP showed marker peak; however marker peak disapeared after resolution of peritonitis at 1 week and 2 weeks of antibacterial therapy except for 3 cases who relapsed in whom marker peak was persisting despite absence of clinical peritonitis. The 3 cases of FP did not show any such marker peak differentiating it from BP. Marker signal represent trans-methylene protons of cyclopropane ring moiety as reported earlier and depicted in Figure 1.



Conclusions: The cyclopropane signal at 0.67 ppm can be marker signal to differentiate BP and FP and persistence of this signal at 2 weeks after clinical resolution of peritonitis predicts RP.

FR-PO833

Peritoneal Mesothelial Cell Sodium Glucose Co-Transporter 1 (SGLT1) Regulates VEGF Production: Potential Target in Ultrafiltration Failure

Eric L. Wallace,[1] Phillip H. Chumley,[1] Leslie J. Jackson,[1] Juling Zhou,[1] Michal Mrug,[1] Jeremy Goodman,[1] Joanne E. Murphy-Ullrich,[1] Edgar A. Jaimes.[2] *[1]Univ of Alabama at Birmingham; [2]Memorial Sloan Kettering Cancer Center.*

Background: D-glucose and vascular endothelial growth factor (VEGF) are important in the development of ultrafiltration failure (UFF) in peritoneal dialysis (PD) . The role of glucose transport in peritoneal mesothelial cells (PMC) in UFF is unknown. Herein we hypothesize that the glucose transporter SGLT1 is increased in response to high glucose and regulates VEGF production.

Methods: PMC, obtained from omental digestion of non-PD patients and from spent PD dialysate, were incubated for 48 hrs under 200mM D-glucose or L-glucose, 200mM mannitol, 200mM 3OMG a non-metabolizable glucose analog transported by SGLT1, 7.5% icodextrin, with and without 50µM phlorizin (Ph), an SGLT1 inhibitor. VEGF was measured by ELISA. mRNA for VEGF and SGLT1 was measured by RT-PCR. Immunofluorescence microscopy for cytokeratin and SGLT1 was performed on human peritoneal biopsies performed at PD catheter insertion (CI) and at catheter revision (CR) after 6 months of PD.

Results: SGLT1 expression was minimal in PMC in biopsies at CI, but abundantly present in PMC in biopsies at CR. PMCs cultured under 200 mM D-glucose had a 6 fold increase in SGLT1 mRNA vs 5mM D-glucose and an increase in VEGF: 70 ±1.9 pg/mg to 2,456 ±189 pg/mg ($p<0.05$). D-glucose stimulation of VEGF was partially inhibited by 50 µM Ph : 6,098± 405 pg/mg to 3,991±289 pg/mg ($p=0.003$). 3OMG also stimulated VEGF: 71± 1.9 pg/mg to 1,474 ±160 pg/mg ($p < 0.01$) that was inhibited by Ph 623 ± 74 pg/mg), suggesting Ph inhibition of VEGF is partly independent of glucose metabolism ($p<0.05$). 200mM L-glucose stimulated VEGF less than D-glucose (543 ± 35pg/mg, $p < 0.01$). This stimulation was inhibited by Ph (123 ± 12 pg/mg). 7.5% icodextrin vs 5mM Glucose did not stimulate VEGF production (47 ± 5.1 pg/mg, $p<0.005$).

Conclusions: SGLT1 expression in PMC is upregulated in response to high D-glucose *in vivo* and *in vitro*. Glucose transport regulates VEGF production under high D-glucose conditions, which may provide a therapeutic target for UFF.

Correlation Between Fibroblast Growth Factor-23, Endothelial Dysfunction, and Inflammatory Markers in Chronic Peritoneal Dialysis Patients and Their Response to Antioxidant Therapy

Mitul Bora. *Nephrology, Ayur Sundra Super Speciality Hospital, Guwahati, Assam.*

Background: Cardiovascular disease (CVD) is the major cause of morbidity and mortality in dialysis patients. Various non-traditional factors like inflammation, acute phase reactants and endothelial dysfunction have been proposed for this increased incidence of

CVD. Increased intact parathyroid hormone and FGF-23 levels are associated with the progression of vascular calcification in peritoneal dialysis (PD) patient. N-acetylcysteine (NAC) acts on atherosclerosis and also improves the endothelial functions. This study was designed to evaluate the correlation between FGF-23, endothelial dysfunction and markers of inflammation in chronic PD patients and to evaluate the effect of three months of therapy of NAC on these parameters.

Methods: All patients underwent Doppler studies to assess endothelial function by the flow mediated dilatation (FMD) of the brachial artery and carotid arterial intima media thickness (CIMT).Brachial artery was imaged during reactive hyperemia (endothelium-dependent, flow-mediated dilatation, FMD) and during glyceryl trinitrate-mediated dilatation (nitroglycerine-mediated dilatation, NMD, endothelium-independent) in all PD patients. NAC was given in the dose of 1200 mg in two divided doses for a period of three months. The associations between different parameter were analyzes using Spearman correlations. All these parameters were repeated after three months of therapy with NAC.

Results: A total of 73 chronic PD patients were enrolled in this study.FGF-23 showed strong positive correlation with serum homocysteine level (r=1.00, P<0.001), hsCRP (R=0.977, P <0.001). ,Endothelium Dependent Dilatation [(EDD) (r = 0.968, P < 0.001)] and CIMT (r = 0.994, P < 0.001), but negatively correlated with Endothelium Independent Dilatation (EID) and Vitamin D level. All these parameters including FGF-23, hsCRP, homocysteine , CIMT and EDD were significantly reduced after three months of therapy with NAC.

Conclusions: FGF-23 correlated well with inflammatory markers and endothelial function. With three months of therapy, NAC significantly reduces the CIMT, inflammatory markers and improves the endothelial function in chronic PD patients.

FR-PO835

SRF Enhances Cell Adhesion, Migration and Peritoneal Fibrosis via Modulating miRNA-199a/214 Cluster in Human Peritoneal Mesothelial Cells

Lijie He, Shiren Sun. *Dept of Nephrology, Xijing Hospital, Xi'an, Shaanxi, China.*

Background: Our previous work showed that serum response factor (SRF) was involved in fibrosis of peritoneal membrane, but the exact underlying mechanism were still unclear. Here we further study the role of miR-199a/214 cluster and the relationship of SRF in peritoneal fibrosis.

Methods: We isolated HPMCs from the effluents of end-stage renal disease (ESRD) patients with peritoneal dialysis (PD), and also used PD dialysis rats model to observe the response of PM to miR-199a/214 cluster and the predicted target CDH1 and CLDN2.

Results: In this study, we found that miR-199a-5p/214 cluster, which was examined to be highly expressed in HG-induced HPMCs by real time PCR, was directly regulated by SRF after HG stimulation. All these HG induced immortal HPMCs became scatter, have the migration ability, lost cell-cell adhesion, and characterized by phenotype markers change with the elevated expression of miRNA-199a/214 cluster, which were also found in these long time treatment of CAPD patients ex vivo or in PD rats. The overexpression of miR-199a/214 cluster leaded to the lower expression of the cell-cell adhesion markers E-cadherin and claudin-2 protein, and the silencing of miR-199a/214 cluster by lentivirus could inhibit HG-induced damage and alleviate fibrosis in PD rats. Depletion of miR-214/miR-199a cluster in HG stimulated HPMCs reduces cell to cell adhesion, migration and phenotypic transition by up-regulating E-cadherin, claudins and downregulating α-SMA in vitro. While overexpression of miR-214 and miR-199a-5p by mimic into HPMCs caused the opposite effects. ChIP and luciferase reporter assays revealed that the active and overexpression of SRF directly promotes the transcription of miR-199a/214, which are examined to be highly expressed in HG-induced HPMCs. Mechanistically, miR-199a-5p and miR-214 were characterized to target the E-cadherin and claudin-2 messenger RNA CDH1 and CLDN2 to contribute to the adhesion of cell to cell or cell to matrix induced by HG of HPMCs in vitro.

Conclusions: Together, this study reveals a new SRF-miR-199a/miR-214 cluster-CDH1/CLDN2 EMT axis which highlights the potential damage of HG and fibrosis in PD.

Therapeutic Targeting of EGFR Protects against Peritoneal Fibrosis in Rats

Li Wang,[1] Na Liu,[1] Andong Qiu,[1] Shougang Zhuang.[1] *[1]Dept of Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China; [2]Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Brown Univ, Providence, RI.*

Background: Long-term PD leads to peritoneal damage and subsequently to peritoneal fibrosis that is characterized by fibroblast activation, collagen fibril accumulation, inflammation, and angiogenesis, but there is still no available treatment for peritoneal fibrosis thus far.

Methods: In the current study, we explored the therapeutic effect of gefitinib, a specific inhibitor of epidermal growth factor receptor (EGFR), on the development and progression of peritoneal fibrosis induced by chlorhexidine gluconate (CG) and high-glucose dialysis fluid in rats.

Results: Daily intraperitoneal injections of CG or high-glucose dialysis fluid induced peritoneal fibrosis as indicated by thickening of the submesothelial area with an accumulation of collagen fibrils and activation of myofibroblasts. This was accompanied by time-dependent EGFR phosphorylation. Administration of gefitinib, a specific EGFR inhibitor, immediately after injury prevented the onset of peritoneal fibrosis, and delayed treatment until a certain degree of peritoneal fibrosis has occurred halted the progression of peritoneal fibrosis. Gefitinib treatment abrogated increased phosphorylation of EGFR, Smad3, STAT3 and nuclear factor (NF)-κB during peritoneal fibrosis. Gefitinib also inhibited overproduction of transforming growth factor-β1 and multiple proinflammatory cytokines as well as infiltration of macrophages to the injured peritoneum. Moreover, gefitinib significantly reduced peritoneal increase of CD31 (+) blood vessels and vascular endothelial growth factor (+) cells after injury.

Conclusions: These results demonstrate that EGFR contributes to peritoneal fibrosis, inflammation and angiogenesis and suggest that EGFR inhibitors may have therapeutic potential in peritoneal fibrosis.

FR-PO837

Effects of Alanyl-Glutamine Addition in Peritoneal Dialysis Fluid on Peritoneal Immune Modulation – A Pilot Clinical Trial

Klaus Kratochwill,[1,2] Rebecca Herzog,[1,2] Manoj K. Bhasin,[3] Seth L. Alper,[3] Andreas Vychytil,[1] Christoph Aufricht.[1] *[1]Medical Univ of Vienna, Vienna, Austria; [2]Zytoprotec GmbH, Vienna, Austria; [3]Beth Israel Deaconess Med. Ctr., Harvard Medical School, Boston, MA.*

Background: Low peritoneal glutamine levels may contribute to reduced immune defense and increased inflammation in the peritoneal cavity. As a pilot clinical trial, PD patients were treated with PD fluid supplemented with 8 mM alanyl-glutamine (AlaGln) and the effect on peritoneal cell immuno-competence was studied by functional assays and transcriptomics using RNA-sequencing (RNAseq) and microRNA (miRNA) profiling of cells derived from PD effluents.

Methods: In an open-label, randomized, crossover clinical trial at the Medical University of Vienna (EudraCT-2012-004004-36), 6 stable PD patients received either standard PD fluid (Physioneal40 3.86%, Baxter) or AlaGln-supplemented PD fluid for an overnight dwell followed by a 4 h peritoneal equilibration test. Cytokine release from *ex vivo*-stimulated effluent cells was assessed as a measure of immuno-competence. Cells were also analyzed by RNAseq (TruSeq Single-end mRNA, Illumina) and miRNA microarray analysis (Affymetrix) using an integrated bioinformatics workflow developed in the Bhasin Lab.

Results: AlaGln treatment significantly increased cytokine release following *ex-vivo* stimulation, consistent with restoration of previously suppressed peritoneal immunocompetence. Peritoneal effluent cell transcripts of 9,797 genes were identified. Unsupervised clustering and principal component analysis revealed partial separation between treatments. Supervised analysis using the paired approach identified 13 differentially expressed miRNAs and 41 differentially expressed genes with >1.5-fold change (P<0.01). Functional enrichment analysis of these genes indicated pathways linked to immune response and modulation.

Conclusions: In summary, AlaGln-mediated improvement in peritoneal leukocyte immuno-competence was correlated with changes in peritoneal leukocyte transcriptome status in well-described clinical samples. To strengthen these promising data, larger numbers of patients will be treated with AlaGln for a prolonged period in an international multi-center RCT.

FR-PO838

Choice of Dialysis Modality for Children with End Stage Renal Disease

Julien Hogan,[1,2] Cécile Couchoud.[2] *[1]Pediatric Nephrology, Robert Debré Hospital, Paris, France; [2]REIN Registry, Agence de la Biomédecine, La Plaine Saint Denis, France.*

Background: Despite many studies that aim to assess the best modality of dialysis, results remain conflicting both in adults and in children. This lack of medical evidence leads commentators to emphasize the importance of patients' choice in the decision process. Thus, we try to assess factors that impact the choice of the dialysis modality in children and to determine which from medical factors, center practices or patients' or families' wishes plays the major role.

Methods: All incident patients <20 years old at start of dialysis, recorded in the French ESRD registry between 2002 and 2013 were included. We used multivariate hierarchical logistic regression models to study patients and centers characteristics associated with the probability of starting with peritoneal dialysis (PD). The effect of centers was assessed by including centers as a random effect.

Results: Among 806 patients treated in 177 centers, 601 (74.6%) started with hemodialysis (HD) and 205 (25.4%) with PD. A higher probability of PD was found in younger children while starting treatment in emergency was associated with a low use of PD. Low and high educational level of the town of residence were both associated with less probability of PD when compared with average educational level. There was a significant variability between centers, that was not explained by patients' case-mix. Being treated in specialized pediatric centers was associated with less probability of PD, while the probabilty of PD was proportional to the rate of PD in the center.

Conclusions: Although little evidence exists to favor a dialysis modality over the other in children, HD remains the predominant modality in France. PD is still mostly offered to the youngest children while it remains underused in patients starting RRT in emergency. However, we found that besides medical factors, centers practices play a major role in the choice of dialysis modality. This raise concerns about the place left to patients' and families' choices and to what extend doctors may influence the final decision. Further pediatric studies focusing on children and parents' wishes are needed in order to provide cares as close as possible to there expectations.

FR-PO839

Clinical Course of Children Born with Chronic Kidney Disease – A Single Centre Experience Christina Taylan,[1] Bernd Hoppe,[2] Eva Maria Haffner,[2] Lutz Thorsten Weber.[1] *[1]Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany; [2]Pediatric Nephrology, Univ Hospital of Bonn, Bonn, Germany.*

Background: The number of babies born alive suffering from chronic kidney disease (CKD) is constantly increasing.

Methods: We analyzed the outcome of infants with CKD and renal replacement therapy (RRT) started within their first year of life. Between 2007 and 2013 17 infants (11 male; 6 female) developed end-stage renal disease resulting in RRT in our department.

Results: All of them received peritoneal dialysis (PD) initially at a median age of 34 [1-334] d. During follow-up 10 children underwent renal transplantation (RTx), 1 child was still on PD at last follow-up, 1 child had to go back to hemodialysis after graft loss and 2 had a recovery of renal function. 3 out of 17 children died during the PD period. Causes of death were severe sepsis twice and one cerebral bleeding. The mean GFR at last follow-up (2.2±0.73 years) of patients who underwent RTx was 105±22.8 ml/min/1.73 m^2. Mean time on dialysis was 17.8±14.3 months before RTx, mean age at transplantation was 29.2±14.2 months. Mental development was measured by Mental Development Index T1 (Bayley Scales of infant development BSID-II) at an average age of 12 [9-16] months and showed developmental delay at the motor, mental and behaviour rating scale. At time of transplantation 6/10 infants had tube feeding, 9/10 were <3. percentile of height, 3/10 were <3. percentile of body weight.

Conclusions: RRT started in the first year of life was associated with reasonable outcome and should be offered to all infants with end stage renal disease. It is, however, associated with a high risk of developmental delay. This work emphasizes the great demands made on an interdisciplinary team of pediatric nephrologists, psychologists and social workers.

FR-PO840

Altered Myogenesis and Oxidative Stress in a Rat Model of Chronic Kidney Disease Keith Avin,[1] Neal X. Chen,[2] Jason M. Organ,[3] Kalisha O'Neill,[2] Sharon M. Moe.[2,4] *[1]Dept Physical Therapy, Indiana Univ, Indianapolis, IN; [2]Div of Nephrology, Indiana Univ, Indianapolis, IN; [3]Dept of Anatomy, Indiana Univ, Indianapolis, IN; [4]VAMC, Indianapolis, IN.*

Background: Skeletal muscle atrophy and impaired muscle function are associated with lower quality of life, and greater disability and mortality risk in those with chronic kidney disease (CKD). However, the pathogenesis of atrophy is unknown.

Methods: We used a slowly, progressive, naturally occurring, CKD rat model (*Cy/+* rat) and its normal littermate (NL). At 35 weeks, we tested muscle strength, sacrificed and collected tissues and blood. RNA and protein were isolated from skeletal muscle and real time PCR and western blot performed.

Results: CKD rats developed sarcopenia evident by reduced cross sectional area ($p<0.05$), increased connective tissue deposition on histology ($p<0.05$), and impaired strength ($p<0.05$). Strength was defined as the maximal amount of force produced during maximal, electrically stimulated dorsiflexion. These findings of atrophy can be explained by reduced regeneration, increased catabolism, or differentiation of muscle stem cells toward myofibroblasts. By PCR, there was increased activation and differentiation of muscle stem cells (reduced Pax-7, increased MyoD and myogenin ($p<0.05$)) and increased proteolytic markers (Atrogin-1 and MuRF-1 ($p<0.05$). Fibrosis may be enhanced via decreased miR-29b ($p<0.05$) and increased Wnt5a ($p<0.01$). Finally myostatin was increased in blood and muscle RNA expression yet no difference in the activin type IIB. The long term consequences of the impaired balance of increased proteolysis and inadequate regeneration is further supported by mitochondrial derangement (electron microscopy) and increased mitochondria complexes I, II and IV ($p<0.05$) despite increased expression of the anti-oxidant nuclear erythroid 2-related factor 2 ($p<0.05$).

Conclusions: In a rat model of CKD, sarcopenia was present despite the activation of myogenic factors. The atrophy is due to a combination of factors including increased myostatin, increased expression of atrogenes, and the presence of oxidative damage. Augmentation of the myogenic and antioxidant responses through treatments may prevent progressive sarcopenia in CKD.

FR-PO841

Can Calcitriol and Calcidiol to Regulate Toll Like Receptors 7, 9 and IL-6 and IFN-γ Expression on Lymphocytes Incubated with Uremic Serum? Maria Dalboni,[1,3] Marion Schneider,[1] Lilian Cuppari,[1] Caren Cristina Grabulosa,[1] Silvia Regina Manfredi,[1] Edgar Maquigussa,[1] Danilo Takashi Aoike,[1] Miguel Cendoroglo Neto,[1,2] Jose Tarcisio Giffoni.[1] *[1]Div of Nephrology, Univ Federal São Paulo, Sao Paulo, Brazil; [2]Medicine, Tufts-New England Medical Center, Boston; [3]Medicine, Univ Nove de Julho, Sao Paulo, Brazil.*

Background: The uremic environment has been reported to induce an inflammatory response and TLR is one of the mechanisms that may be involved in this response. In addition, it has been recognized that low levels of this vitamin can be associated with the deregulation of the inflammatory response. Thus, the purpose of this study was evaluate the effect of 25 (OH)D3 and 1,25 (OH)2D3 on lymphocytes B and T for IL-6, IFN-γ TLR-7 , TLR-9, VDR, CYP27 and CYP24 expression in presence of uremic serum.

Methods: PBMC isolated by Ficoll-Hipaque from health subjects were used to analyze lymphocytes. These cells were incubated with normal or uremic serum in presence or absence of 25 $(OH)D_3$ or 1,25 $(OH)_2D_3$ for 24 h in a 37ºC, 5% CO_2. We use flow cytometry to evaluate IL6, IFN-γ, TLR7, TLR9, VDR, CYP27 and CYP24 expression on lymphocytes B and T.

Results: Uremic serum induced a significant increase in IL6, IFNγ, TLR7, TLR9, VDR, CYP27 and CYP24 expression in B and T lymphocytes ($p<0.05$). Both lymphocytes incubated with 25 $(OH)D_3$ or 1,25 $(OH)_2D_3$ had a significant reduction in IL-6 and TLR9. As CYP24 had a higher expression and this can to induce a degradation of 1,25 (OH)2D3, we did a CYP24 silencing, and observed an additional decreased in IL6, IFNγ, TLR7 and TLR9 expression on B and T lymphocytes for both treatment when compared to effect of these vitamins alone ($p<0.05$). In the same condition, we also observed an increase VDR expression.

Conclusions: Our results suggests that both 25 $(OH)D_3$ and 1,25 $(OH)_2D_3$ had immunomodulatory effects in B and T lymphocytes. This *in vitro* model confirm the anti-inflammatory role of Vitamin D in uremia environment. However, these effects of Vitamin D were enhanced after CYP24 silencing. So, this data support that CYP24 inhibitors may also be a target of treatment in association with vitamin D supplementation to improve a immunological response mechanisms.

FR-PO842

Toll Like Receptors 2, 4, TNF-α, IL-6 and IL-10 Expression on Leukocytes from Hemodialysis and Pre-Dialysis Patients Maria Dalboni,[1,3] Jose Tarcisio Giffoni,[1] Silvia Regina Manfredi,[1] Jacqueline Ferritto Rebello,[3] Rodrigo Barbosa de oliveira Brito,[3] Miguel Cendoroglo Neto,[1,2] Caren Cristina Grabulosa.[1] *[1]Nephrology Div, Univ Federal de São Paulo, Sao Paulo, Brazil; [2]Medicine, Tufts-New England Medical Center, Boston; [3]Medicine, Univ Nove de Julho, Sao Paulo, Brazil.*

Background: Toll-like receptors (TLR) are involved in immunologic response. The TLRs expression and cytokines association in neutrophils and monocytes from CKD patients is unclear.To evaluate TLR-2, TLR-4, TNF-α, IL-6 and IL-10 expression in neutrophils (PMN) and monocytes (MN) from Hemodialysis (HD) and Pre-dialysis (PD) patients.

Methods: Blood samples from 43 hemodialysis (HD) patients (collect before the beginning of the second week hemodialysis session), 46 pre-dialysis (PD)(estimated by *Modification of Diet in Renal Disease* (MDRD) and 70 age-and gender-matched healthy volunteers (CONT) were analyze for TLR2 and TLR4 expression on PMN and MN by Flow cytometry. The TNF-α, IL-6 and IL-10 cytokines were analyzed by ELISA.

Results: The expression of TLR2 and TLR4 on neutrophils from HD patients was higher than PD and CONT patients ($p<0.001$). In monocytes, TLR-2 expression was higher in HD patients compared to others groups ($p<0.001$) and TLR4 expression was higher inPD patients compared to the CONT and HD patients ($p<0.001$). Regarding to cytokines, we observed that HD patients showed an increase of TNF and IL-6 levels compared to CONT (4.6±5.3 vs 1.9±1.3 and 6.0±3.2 vs 2.5±2.1; $p<0.001$, respectively) and IL-10 from HD patients were higher than PD and CONT patients (115± 166 vs 36±82 and 27±62, respectively).We also observed a significant correlation between TLR2 and TLR4 and TNF-α on neutrophils ($r = 0.30$; $p = 0.02$ and $r = 0.34$; $p = 0.01$, respectively). In respect to monocytes, only TLR2 had correlation with TNF-α and IL-6 ($r = 0.30$; $p = 0.02$ and $r = 0.24$; $p = 0.03$, respectively).

Conclusions: It is possible that the deregulation of TLR2 and TLR4 expression on leukocytes may be caused by uremic toxins in CKD population. Besides, the high expression of TLR2 and TLR4 in these cells resulted in an increase of TNF-α and IL-6 levels, suggesting that TLRs are associated with inflammatory mechanisms in uremic patients.

FR-PO843

Effect of Cholecalciferol Supplementation on Toll-Like Receptors 7, 9 Expression and IL-6 and IFN-γ Intracellular on B and T Lymphocytes on Chronic Dialysis Patients Maria Dalboni,[1,3] Marion Schneider,[1] Lilian Cuppari,[1] Caren Cristina Grabulosa,[1] Silvia Regina Manfredi,[1] Edgar Maquigussa,[1] Danilo Takashi Aoike,[1] Miguel Cendoroglo Neto,[1,2] Jose Tarcisio Giffoni.[1] *[1]Div of Nephrology, Univ Federal de Sao Paulo, Sao Paulo, Brazil; [2]Medicine, Tufts-New England Medical Center, Boston; [3]Medicine, Univ Nove de Julho, Sao Paulo, Brazil.*

Background: Vitamin D deficiency is highly prevalent among patients in all stages of CKD. Studies have reported that the Vitamin D deficiency is associated with mortality and morbidity in CKD patients and may modulate TLRs that are involved in inflammatory responses. Thus, the purpose was evaluate the effect of cholecalciferol on IL-6, IFN-γ TLR-7 and TLR-9 expression in lymphocytes B and T in patients on dialysis with vitamin D hipovitaminosis.

Methods: In a randomized, placebo-controlled, double-blind study, we investigated the effect of cholecalciferol (100,000 UI once per week or placebo) for 3 months, in patients on chronic dialysis, who had nutritional vitamin D deficiency . The $25(OH)D_3$ detection was performed by quimioluminescence and IL6, IFN-γ, TLR7, TLR9, VDR, CYP27 and CYP24 expression by flow cytometry on lymphocytes B and T.

Results: After 3 months of treatment , Cholecalciferol increased $25(OH)D_3$ levels (16,00±4,44 vs 42,81±13,06, p=0,01) and reduced PTH levels (525,3 (128-1775) vs 484,8 (86-2264, p=0,03), but have no impact on FGF23 levels. Additionally, we observed a reduced expression of TLR7 (305±78 vs 252±45, p=0,01), TLR9 (1864±700 vs 1084±370, p=0,001 and CYP24 (284±136 vs 200±86, p=0,01), and increased of VDR (730±360 vs 965±440, p=0.006) and CYP27 (245±38 vs 442±380, p=0.04) expression.

Conclusions: Cholecalciferol treatment in dialysis patients showed to be efficient to correct hipovitaminosis D. In addition, we observed impact of $25(OH)D_3$ repletion on reduction of expression of the TLR7, TLR9, IFN-γ and improve of regulatory mechanisms

associated with intracellular production of vitamin D on lymphocytes from CKD patients. These results suggests that cholecalciferol treatment play an important role on TLRs expression as an anti-inflammatory and that this may contributed to a better systemic inflammation response in CKD patients.

FR-PO844

The Effect of Selenium Deficiency on Thyroid Hormone and Cardiovascular Diseases in Hemodialysis Patients So Mi Kim,[1] Eun kyoung Lee,[2] Yun Jung Oh,[3] Ja Seon Kim.[4] *[1]Div of Nephrology, Dept of Internal Medicine, Jeju National Univ Hospital, Jeju National Univ School of Medicine, Jeju, Jejudo, Republic of Korea; [2]Div of Nephrology, Dept of Internal Medicine, Dankook Univ Hospital, Cheonan, Chungnaam, Republic of Korea; [3]Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Jejudo; [4]Div of Nephrology, Dept of Internal Medicine, Incheon sarang Hospital, Incheon, Kyoungkido, Republic of Korea.*

Background: Selenium deficiency is known to associate with impairment of thyroid hormone and cardiovascular diseases such as ischemic heart disease (IHD), cardiomyopathy or sudden death. In hemodialysis (HD) patients, various causes may contribute to selenium deficiency, including malabsorption, alteration of metabolism, and removal through dialysis itself. Therefore, we tried to investigate the effect of selenium deficiency on thyroid hormone and cardiovascular diseases in HD patients.

Methods: This cross-sectional study enrolled 83 HD patients. They were divided into two groups based on serum selenium levels: 62 patients were normal level and 22 patients were selenium deficient. Thyroid hormones such as TSH, free T4 were measured. And cardiovascular diseases, including IHD, heart failure or cardiomyopathy, were evaluated.

Results: Thyroid hormone impairment, including hypothyroidism and subclinical hypothyroidism, showed higher tendency in selenium deficient group than that in non-selenium deficient group. (27 % vs 10 % P=0.06) The prevalence of IHD was significantly higher in selenium deficient group than that in the non-selenium deficient group. (59% vs 21 %, p=0.04) But there was no difference in heart failure and cardiomyopathy. The patients with thyroid hormone impairment showed high prevalence of IHD, and the coincidence of thyroid hormone impairment and IHD was also significantly higher than that in selenium deficient group than that in non-selenium deficient group. (18% vs 4%, p=0.014).

Conclusions: This study showed the significant high prevalence of thyroid hormone impairment and IHD in HD patients with selenium deficiency. Selenium deficiency may be affect heart disease, associating with thyroid hormone impairment.

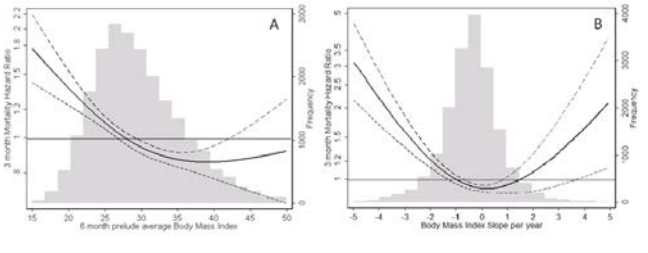
FR-PO845

Associations of Prelude (Pre-ESRD) BMI and Weight Change with Early Dialysis Mortality Among U.S. Veterans: A Transition of Care in CKD Study Elani Streja,[1] Melissa Soohoo,[1] Joline L.T. Chen,[1] Amanda R. Tortorici,[1] Jennie Jing,[1] Danh V. Nguyen,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UTHSC.*

Background: In end stage renal disease (ESRD) lower body mass index (BMI) portends a higher risk of mortality while obesity is protective, the so-called obesity paradox. However, the association of BMI and change in BMI over time in the pre-ESRD period and early post-ESRD mortality is unknown. We hypothesized that lower and decreasing BMI prior to transition to ESRD may be associated with higher early dialysis death.

Methods: In a cohort of 22,716 US veterans who transitioned to dialysis between 10/2007 and 9/2011 with available BMI values within the last 2 year prelude period (prior to ESRD transition), we examined the association of 6 month average BMI and 2 year BMI slope as continuous predictors of all-cause mortality in the first 3 months after transition, using restricted cubic spline analyses and Cox models adjusted for age, sex, race, ethnicity, cause of ESRD, and region. In the models of BMI slope, we also adjusted for BMI level at the time of transition.

Results: The mean±SD age was 69±11 yrs, 27% were African-American, 7% Hispanic, and 49% diabetic. There was a reverse J-shaped association between BMI and mortality, where patients with BMI <27 kg/m^2 were at higher risk of death (Figure A). When examining changes in weight over the 2-year prelude there was a U-shaped association where patients with little to no-change in BMI (-1 to +1 kg/m^2 per year) exhibited the best survival (Figure B).



Conclusions: Among veterans transitioning to dialysis, obese patients and those patients with little to no weight change in the last 2 years prior to ESRD have the greatest survival in the first 3 months post transition. Weight change in late stages of pre-dialysis CKD, possibly due to uremic wasting and fluid gain, portend poor outcomes, and could be used to identify at-risk patients.

FR-PO846

Nutritional Assessment for Incident Elder Dialysis Patients Ikuto Masakane,[1] Yuya Sakai,[2] Miho Suzuki.[2] *[1]Yabuki Hospital, Nephrology, Yamagata, Japan; [2]Yabuki Hospital, Dept of Health and Nutrition.*

Background: Nutritional status is one of the most powerful predictors of patient survival in chronic dialysis patients especially in elders. It is generally accepted that aging itself is one of the risk factors of malnutrition. Recently the patients who started dialysis have become older and older as the average age of incident dialysis patients in Japan is nearly 70 years old. It is very meaningful to evaluate the status of malnutrition in new elder dialysis patients, its time-course and to establish strategies for preventing progression of malnutrition.

Methods: The nutritional status of 257 incident dialysis patients in YHG was retrospectively evaluated by MIS. The nutritional status on 37 patients out of the 257 patients has been followed for 3 years. The "malnutrition" was diagnosed as "moderate-severe" in MIS and fulfill of the diagnosis of PEW. Patients greater than 75 years old were categorized as Elder and patients under 75 years old were as Non-elder. The statistical significance of time-dependent changes in nutritional status was evaluated by paired-T test.

Results: The prevalence of malnutrition at the point of dialysis initiation by MIS in average was 7%, 12% in Elder and 5% in Non-elder. The nutritional status had been improved in the non-elder but not in the elder. The lean body mass had decreased in the first year of dialysis vintages in both groups and had remained the same in the following 2 years. Body fat mass had increased consistently for 3 years in non-elderly. It had increased for the first 2 years but had begun to decrease in the third year in the elder. Protein and energy intake per ideal body weight were lower in elder dialysis patients.

Conclusions: Malnutrition in elder dialysis patients was often accompanied by the initiation of chronic dialysis therapy and would gradually develop in the maintenance period. In order to protect the progression of malnutrition several proposals were addressed as the proper timing of the initiation of dialysis before the deterioration of daily activities; nutritional education for sufficient energy and protein intake, exercise education and sufficient dialysis prescription with biocompatible dialysis membranes.

FR-PO847

Uric Acid Is a Determinant of Glomerular Filtration Rate in Inflammatory Conditions Suad Ma Hannawi, Issa AL Salmi. *Medicine, The Ministry of Health, Dubai, United Arab Emirates; The Renal Medicine Dept, The Royal Hospital, Muscat, Oman.*

Background: The presence of gout or a baseline serum uric acid in the upper range are possibly stronger predictors of first CV events than some traditional CV risk factors or parameters of inflammation. Presence study analysis UA determinants in relation to GFR.

Methods: Patients attending the only centre of MOH in Dubai were studied during their OPD rheumatology visit from Jan 2014 till Dec 2014. Many laboratory tests including UA were performed. MDRD formula was used to get eGFR. Simple statistical and regression models were performed. Variables that not normally distributed being log transformed.

Results: 79 (88.6%F,11.4%M) were recruited with mean age46.4(13.4) years. Mean UA was249.8 (84.4), eGFR137.1(50.5)(59.6,306.1).

Regression analysis found a negative relationship between UA and GFR (P<0.001,-0.004,-0.002) and positive relationship between uric acid and age (p=0.032, 0.001-0.011), urea (p<0.001,0.041-0.137), microalbuminuria (p=0.046,0.000-0.001), microalbumin/cr (p=0.024,0.001-0.013), SBP(P=0.014,0.001-0.009), DBP(p==0.025,0.001-0.014), age at Dx RA (P=0.028,0.001-0.010), monocyte% (p=0.009,0.013-0.088), monocyte count (p=0.003,0.015-0.776) TG (p=0.034,0.009-0.216), BUT also negative with cholesterol (p=0.033,-0.148,-0.007),

Uric acid multiple model has maintained a strong correlation with eGFR (p=0.005), monocyte count (0.009), cholesterol (p.007),microalbuminuria(p=0.01), after adjustment for all the above mentioned variables.

Conclusions: UA is determined by eGFR and other renal parameters in inflammatory condition. On the other hand, uric acid increase the risk of renal impairment and CVD in inflammatory condition. Thus, uric acid level might be an elemental key factor that result in high renal and CV associated morbidity and mortality in the inflammatory diseases. UA is a powerful independent predictor of prevalent renal dysfunction but was also a significant predictor of progression of renal disease. UA may not be just an innocent bystander but may be an active player in the pathogenesis of renal disease by causing endothelial dysfunction, intrarenal vascular disease and renal impairment in inflammatory conditions.

FR-PO848

Does Nutritional Status and Serum Electrolytes Change when Dialysis Patients Reduce Their Fluid Overload? Penny Faith Sheppard,[1] Suzette Thompson,[2] Laura Rosales,[1] Nathan W. Levin,[1] Peter Kotanko,[1] Fansan Zhu.[1] *[1]Renal Research Inst, New York, NY; [2]Fresenius Vascular Care, New York, NY.*

Background: Electrolyte balance between the intracellular (ICV) and extracellular (ECV) fluid compartment is essential in the control of normal physiological functions. Nutritional status is mainly reflected by ICV. In hemodialysis (HD) patients the relationship between electrolyte control and management of fluid balance is not completely understood. We aimed to evaluated whether the degree of reduction of fluid overload affects the measurement of ICV, and concentrations of serum albumin (Alb), sodium, potassium, and calcium.

Methods: Fifty six HD patients were studied. At baseline (BL), the fluid status was evaluated by calf biompedance spectroscopy (cBIS). If patient's dry weight (DW) was not reached by criteria of cBIS DW, the post target weight was gradually reduced (Zhu et al,

Physiol Meas, 29:S530-S516, 2008). At six months follow up, the patients either reached DW or did not (NDW) due to difficulty in prolonging treatment time. ECV and ICV, weight, and systolic blood pressure (SBP) were measured pre and post HD. Comparison of all parameters between BL and follow up were made using student *t* test.

Results: Thirty one patients reached DW and 25 did not. Weight and ECV were significantly reduced during follow up. However, ICV, electrolytes and Alb concentrations did not change between different fluid statuses. Post HD SBP significantly decreased from BL to the end of the study in DW but not in NDW groups.

Conclusions: Although extracellular fluid (ECV) was largely reduced, the ICV and serum concentrations of sodium, potassium, and calcium did not differ significantly. This implies that there is no fluid or mass shift from ICV to ECV, suggesting over all isotonic removal of sodium and that nutritional status is not changed by attainment of dry weight.

Table 1

	Na+ (mEq/l)	K+ (mEq/l)	Ca++ (mEq/l)	Alb (mEq/l)	kt/V	Pre HD ECV (L)	Pre HD ICV (L)
BL (n=31)	138.2±3.8	4.7±0.8	9.1±0.6	3.9±0.4	1.63±0.3	16.8±3.6	18.5±5.4
DW	138.7±3	4.7±0.7	9.3±0.6	4.0±0.3	1.7±0.3	15.8±3.1**	18.1±5.1
BL (n=25)	139.3±2.2	4.4±0.7	8.95	4±0.05	1.28±0.3	19.8±3.1#	18.4±5.2
NDW	140.5±3.1	5.0±1.1	8.8±0.6	3.9±0.3	1.53±0.3	20.1±3.5**,#	18.9±4.9

*and** indicate significant (p<0.05, or p<0.01) difference between BL and DW or BL and NDW.
indicate difference (p<0.05) between DW group and NDW group.

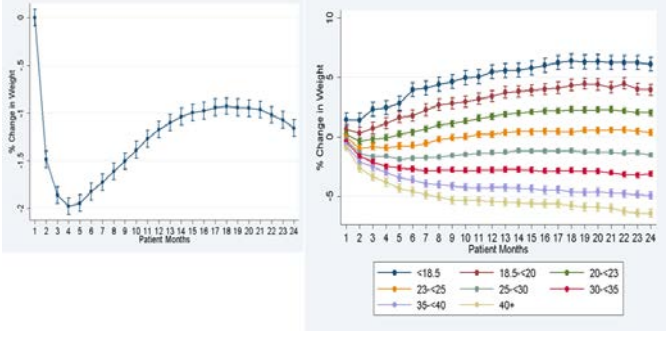
FR-PO849

Trends in Weight Change During the First Two Years of Transition to Hemodialysis Treatment Vyvian Ngo,[1] Elani Streja,[1] Anna Mathew,[2] Tae Hee Kim,[1] Yoshitsugu Obi,[1] Connie Rhee,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]Hofstra North Shore LIJ Health System; [3]UTHSC.*

Background: Some hemodialysis patients may undergo rapid weight loss in the first few months of starting dialysis, but the nature of this trend has not yet been characterized in large nationally representative studies. We hypothesized the trajectory of weight change during the first 24 months of hemodialysis therapy may differ by baseline body mass index (BMI).

Methods: We examined percent post-dialysis weight (kg) change from baseline in 37,759 incident hemodialysis patients who initiated dialysis in a large US dialysis organization in calendar years 2007-2011 and who survived the first 2 years of hemodialysis. Trends of percent weight change over time were analyzed using crude and case-mix adjusted mixed effects models. Baseline BMI was categorized into 8 categories (<18.5, 18.5-<20, 20-<23, 23-<25, 25-<30, 30-<35, 34-<40, 40+ kg/m^2).

Results: Patients were 60±14 years old, 64% diabetics, 44% female, and had an average starting weight of 82±22 kilograms. Patients reached a nadir of weight at the 5th month of dialysis with an average 2% weight loss from baseline. At 14 months, patients' weight stabilized at an average of 1% drop from baseline. However, trends differed across groups of baseline BMI groups. Underweight (BMI <18.5) did not experience weight loss but instead gained approximately 6% of their weight by the 24th month. Obese patients (BMI >40) did not reach a nadir and lost approximately 6% of their weight by the 24th month.



Conclusions: Baseline BMI can affect the trajectory of weight change over the first two years in hemodialysis patients. Further studies are needed to better understand the cause of these differences and their impact on clinical outcomes.

FR-PO850

Significance of Renal Autonomic Nerves in the Reduction of Body Weight by SGLT2 Inhibitors Aika Hagiwara, Kazutoshi Miyashita, Masaaki Sato, Hiroyuki Inoue, Kentaro Fujii, Masanori Tamaki, Hiroshi Itoh. *Nephrology, Endocrinology and Metabolism, School of Medicine, Keio Univ, Shinjuku, Tokyo, Japan.*

Background: Sodium-glucose co-transporter (SGLT) 2 inhibitors decrease not only serum glucose level but also body weight significantly. Similarly, it is reported that renal denervation (RDN) decreases body weight, in addition to blood pressure. The urinary glucose might have a relationship with sympathetic activation that controls body weight. however, the relationship has not been elucidated.

Methods: The present study examined the roles for renal autonomic nerves in the weight reduction by SGLT2 inhibitors through performing RDN on mice fed on a high-fat diet. The C57BL/6 mice fed on a high-fat diet were divided into 4 groups; control group, RDN group, SGLT2 inhibitor group and SGLT2 inhibitor with RDN group. The body weight, glucose tolerance, tissue weights, tissue hormone sensitive lipase (HSL) activity and noradrenalin concentration were examined. The SGLT2 inhibitor (tofogliflozin 50 mg/kg pellet) was administered to mice from 8 weeks old mixing it in the high-fat diet (60 Kcal% fat). RDN was performed at 7 weeks old by surgically stripping the renal arteries and coating the vessels with a solution of 10% phenol in ethanol.

Results: The body weight at 16 weeks old significantly decreased in the SGLT2 inhibitor group. In that group, the catecholamine levels in subcutaneousfat and the activity of HSL which was measured by the phosphorylation level were increased. On the other hand, RDN with SGLT2 inhibitor group significantly weakened the degree of the reduction of body weight by the SGLT2 inhibitor associated with suppression of the catecholamine levels and the activity of HSL in the adipose tissue. In RDN without SGLT2 inhibitor group, the body weight significantly decreased; however, HSL in the adipose tissue was not activated.

Conclusions: These results indicate that HSL activation in the adipose tissue mediated by the renal autonomic nerves was involved in the mechanism of weight-reduction by SGLT2 inhibitors. The renal autonomic nerves were suggested to have a role in the control of tissue HSL activity and body weight.

FR-PO851

The Combination of Walking Exercise and Branched Chain Amino Acid Recovered Response of Protein Synthesis in Low Protein Diet Fed Chronic Kidney Disease Model Rats Takuya Yoshida, Hiromichi Kumagai. *Dept of Clinical Nutrition, Univ of Shizuoka, Shizuoka, Japan.*

Background: Low protein diet (LPD) protects progression of renal injury in patients with chronic kidney disease (CKD). However, LPD may accelerate muscle wasting in these patients. The exercise and branched chain amino acid (BCAA) are known to increase the muscle synthesis by activating mTOR signals pathway. The aim of this study is to investigate whether walking exercise and BCAA would increase muscle protein synthesis in LPD fed CKD (5/6 nephrectomized) rats.

Methods: CKD rats were fed LPD or LPD fortified with BCAA diet (BD), and about half of the each group were loaded with the walking exercise (7 weeks of treadmill, 15 m/min, 1 hour/day, 5 days/week). After 7 weeks, the kidney and the soleus muscle were collected to evaluate the renal fibrosis and the muscle protein synthesis, respectively.

Results: The renal function and fibrosis were not different between LPD and BD fed CKD rats, and the walking exercise did not accelerate renal damage in both LPD and BD fed CKD groups. The walking exercise increased the phosphorylation of p70s6kinase, a biomarker of mammalian target of rapamycin complex 1 activity, in soleus muscle of LPD and BD fed CKD rats. However, the phosphorylation of p70s6kinase was lower in LPD fed CKD rats when compared with sham-operated groups and BD fed CKD group.

Conclusions: CKD reduces activation of muscle protein synthesis. Combination of walking exercise and BCAA recovered the muscle protein synthesis in CKD rats. These results suggest combination of walking exercise and BCAA may be beneficial to improve the muscle protein synthesis in CKD.

FR-PO852

Unacyl-Ghrelin: A Key Molecule in Uraemic Cachexia in Children and Adolescents Alice Monzani,[1] Michela Perrone,[2] Sara Testa,[2] Fabio Paglialonga,[2] Silvia Consolo,[2] Gianluigi Ardissino,[2] Francesca Tel,[2] Marta Lepore,[2] Stefani Rotondo,[2] Antonietta Biasuzzi,[2] Luciana Ghio,[2] Gianni Bona,[1] Alberto Edefonti.[2] *[1]Div of Pediatrics, Univ del Piemonte Orientale, Novara, Italy; [2]Pediatric Nephrology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

Background: Cachexia and poor growth are common in children with chronic kidney disease (CKD). Several mechanisms are involved, including loss of appetite and poor food intake. Unacyl-ghrelin (UAG) is known to produce an inhibitory effect on feeding. We measured UAG levels in children and adolescents with CKD stage II-IV on conservative treatment (CKD-CT), on haemodialysis (CKD-HD) and after transplantation (Tx), compared to healthy controls, in relation to biochemical and anthropometric parameters.

Methods: Plasma UAG levels were measured by ELISA in 43 CKD-CT, 20 CKD-HD, 48 Tx and 43 healthy children. Urea and creatinine levels were measured in all subjects and GFR was calculated by Schwartz formula. Weight, height and bicipital, tricipital, subscapular and suprailiac folds were measured, and BMI z-score, fat-mass and fat-free mass pro body weight (FM/BW and FFM/BW, respectively) were calculated.

Results: Mean UAG levels were significantly higher in CKD-HD (1444.75±1211.44 pg/ml) than in CKD-CT (582.24±546.93 pg/ml, p=0.001), in Tx (491.05±532.82 pg/ml,p<0.0001) and controls (245.29±181.07 pg/ml, p<0.0001). UAG levels were positively correlated with serum creatinine and urea and negatively correlated with GFR, also after adjustment for gender, age, pubertal status and BMI z-score (p<0.0001 for each model). A negative correlation was found between UAG and BMI z-score (R=-0.371, p<0.0001) and between UAG and both FM/BW and FFM/BW (R=-0.518, p <0.0001 and R = -0.319, p = 0.004, respectively).

Conclusions: UAG seems to be a promising inverse biomarker of nutritional status in children with CKD, strictly related to the degree of renal impairment.

FR-PO853

Visceral Fat Area Is Associated with Renal and Cardiac Function in a Population with Normal or Mildly Impaired Renal Function Sung jun Kim,[1,2] Yunju Nam,[1] Hyeon Seok Hwang,[1] Seok Joon Shin,[1,2] Hye Eun Yoon.[1,2] *[1]Internal Medicine, The Catholic Univ of Korea, Seoul, Korea; [2]Internal Medicine, Incheon St. Mary's Hospital, Incheon, Korea.*

Background: Visceral fat is involved in the development of metabolic and cardiovascular diseases. This study was to evaluate the association between visceral fat area (VFA) and renal and cardiac function and arterial stiffness in a population with normal or mildly impaired renal function.

Methods: This cross-sectional study included 719 middle-aged adults who underwent a voluntary health check-up program. Participants with estimated glomerular filtration rate (eGFR) below 60 mL/min/1.73m^2 were excluded. VFA was measured using bioimpedance analysis. Subjects were divided into tertiles according to their VFA. The associations between VFA and eGFR, brachial–ankle aortic pulse wave velocity (baPWV), and echocardiographic parameters were investigated.

Results: Across the tertiles of VFA, there was a significant trend for decline in eGFR (P<0.001), increase in baPWV (P<0.001) and left ventricular mass index (LVMi, P<0.001), and decrease in the ratio of early mitral inflow velocity to peak mitral annulus velocity (E/E', P<0.001). VFA showed significant correlations with eGFR (r = -0.15, P<0.001), baPWV (r = 0.28, P<0.001), LVMi (r = 0.31, P<0.001), and E/E' (r = 0.21, P<0.001). In multivariate analysis, VFA was linearly associated with eGFR (β = -0.06, 95% confidence interval [CI] -0.11 – -0.01, P=0.02), LVMi (β = 0.08, 95% CI 0.06 – 0.10, P<0.001), and E/E' (β = 0.01, 95% CI 0.006 – 0.019, P<0.001), after adjustments for cardiovascular risk factors. In contrast, total body fat was not associated with eGFR.

Conclusions: VFA is associated with renal and cardiac function in middle-aged adults with normal or mildly impaired renal function. Measuring VFA may predict risks of renal and cardiac diseases.

Serum Ferritin <70 µg/L Predicts Functional Iron Deficiency in Patients with Chronic Kidney Disease Neha Garg, Mrinalini Kotru, Om Prakash Kalra, Meera Sikka. *Pathology, UCMS and GTBH, Delhi, New Delhi, India.*

Background: Chronic Kidney Disease (CKD) is a major public health problem with anemia occurring early in the course of disease. Its most common cause is erythropoietin deficiency which can be effectively treated with erythropoiesis stimulating agents. However most of the patients do not respond adequately due to development of Functional Iron Deficiency (FID). The current diagnostic criteria for FID as recommended by KDOQI 2006 tend to miss the diagnosis of FID. The study was conducted to explore the role of hsCRP and Interleukin-6 (IL-6) along with Serum Ferritin (SF) in improving the efficacy of this criteria.

Methods: 77 clinically diagnosed patients of CKD (Stage 3, 4 and 5) of either sex, age >18 years with Hb <11 g/dL were included in the study. Complete clinical history and physical examination was done. Complete hemogram with peripheral smear, serum iron, total iron binding capacity, Transferrin Saturation (TSAT), SF, transferrin receptors (sTfR), hsCRP, IL-6, ESR were estimated.

Results: sTfR/log ferritin (taken as gold standard) detected 31/77 patients as having iron deficient erythropoiesis. Out of these 31 patients, 12 patients had SF <12 µg/L indicating absent iron stores. Remaining 19 patients had FID. In these cases, TSAT <20% and SF >100 µg/L detected FID in only 2 patients with a sensitivity of 6.45%. SF at a cut-off <70 µg/L showed the best sensitivity (83.87%) and specificity (73.91%) in detecting FID in these patients and identified 14/19 cases of FID. The 5 FID cases who were missed had raised hsCRP. In the absence of raised hsCRP, SF <70 µg/L had very good sensitivity (100%). However, in the presence of raised hsCRP sensitivity was reduced (79.16%).

Conclusions: TSAT <20% and SF >100 µg/L had a sensitivity of only 6.45%. However, SF <70 µg/L emerged as the most sensitive and specific in identification of iron deficient erythropoiesis. SF >12 µg/L - SF <70 µg/L was able to identify 14/19 cases of FID. Also, hsCRP could be used to stratify the CKD group in which FID could be detected with high sensitivity and specificity.

Chronic Inflammation Is Associated with Poor Clinical Outcomes Independent of Mineral Metabolism Abnormalities in the HEMO Study Anna Jeanette Jovanovich,[1,2] Eugene J. Nuccio,[2] Alfred K. Cheung,[3,4] Tom Greene,[4] Michel Chonchol,[2] Kristen L. Nowak.[2] *[1]Denver VA Medical Center; [2]Univ of Colorado Denver; [3]VA Salt Lake City; [4]Univ of Utah.*

Background: Epidemiological studies show a high prevalence of chronic inflammation, vitamin D deficiency, and fibroblast growth factor 23 (FGF23) excess in hemodialysis patients. Whether the relationships of high circulating C-reactive protein (CRP) and interleukin-6 (IL-6) with all-cause mortality and cardiac and infectious events are attenuated in the presence of circulating markers of mineral metabolism is unknown.

Methods: We studied the association of inflammatory markers (CRP and IL-6) with all-cause mortality, and cardiac and infectious hospitalizations and deaths among 1340 subjects from the Effect of Dialysis and Membrane Flux in Maintenance Hemodialysis (HEMO) trial. Cox regression models adjusted for important confounding variables: demographics, comorbidities, Kt/V, dialyzer, smoking, albumin, and mineral metabolism markers including serum calcium, phosphorus, intact parathyroid hormone, 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D, and FGF23.

Results: Mean age was 58±14 years, 56% were female, and 63% were black. Median (IQR) CRP and IL-6 levels were 6.1 (2.6-15.2) mg/L and 3.2 (1.7-6.9) pg/mL, respectively. Over mean 2.84 years follow-up, there were 582 deaths, 514 cardiovascular events, and 499 infectious events. Among subjects with levels in the highest quartile compared to the lowest quartile, both CRP and IL-6 were significantly associated with all-cause mortality in adjusted analyses, odds ratio (OR) 1.96 (95% CI, 1.27-3.02) and OR 1.51 (95% CI, 1.02-2.23), respectively. However, only CRP, was associated with cardiovascular disease events (OR 1.90; 95% CI, 1.04-3.44) and infectious events (OR 3.84; 95% CI, 1.37-10.74) among subjects with levels in the highest quartile compared to the lowest quartile.

Conclusions: CRP and IL-6, were significantly associated with all-cause mortality independent of mineral metabolism abnormalities. Only CRP was significantly associated with cardiovascular disease and infectious disease events independent of mineral metabolism abnormalities among subjects in the HEMO trial.

Assessment of Protein-Energy Wasting: Comparing a New PEW Score and the MIS in Chronic HD Patients Camiel LM de Roij van Zuijdewijn,[1] Muriel P. Grooteman,[1] Peter J. Blankestijn,[2] Menso Jan Nubé,[1] Pieter M. Ter Wee.[1] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands.*

Background: the assessment of protein-energy wasting, a syndrome of decreased bodily protein and energy fuels, remains debated. Recently, a French group introduced a new PEW score, encompassing BMI, serum creatinine, nPNA and serum albumin. In a cohort of chronic hemodialysis patients, we compared the predictive value of this score with the Malnutrition Inflammation Score (MIS) using all-cause mortality as end point. Furthermore, we investigated which of these scores correlates best with quality of life (QOL).

Methods: from data of the CONvective TRAnsport STudy (CONTRAST), the new PEW score and the MIS were determined at baseline. QOL was measured with the Kidney Disease QOL-Short Form 36, which results in 2 general and 12 kidney-disease specific domains of QOL. Discrimination and calibration for mortality were tested by Harrell's C Statistic and the Hosmer-Lemeshow Goodness-of-Fit test, respectively. Spearman's rank correlation coefficient ρ was used to determine correlations between a test and the various QOL domains.

Results: 489 out of 714 patients were analyzed. 183 died during follow-up (mean 3.15±1.78 years). Discrimination for mortality was higher for MIS than the new PEW score (Harrell's C statistic 68.0 [95% CI 65.7-69.8] and 61.0 [95%CI 59.0-63.3], respectively). Furthermore, mortality calibration was adequate for MIS (p=0.65), but not for the new PEW score (p=0.03). Lastly, MIS correlated with 13 domains of QOL (ρ's between -0.47 and -0.12), whereas the new PEW score only correlated with the physical component score (ρ 0.18).

Conclusions: both the MIS and the new PEW discriminate for mortality, but the MIS performs better. Furthermore, only the MIS is properly calibrated. Third, the MIS correlates with more QOL domains with higher correlation coefficients. Therefore, we conclude that MIS is preferred over the new PEW score in assessing PEW.

FR-PO857

Change in MIS Over 1 Year Is Not Associated with Mortality in Chronic Hemodialysis Patients Camiel LM de Roij van Zuijdewijn,[1] Muriel P. Grooteman,[1] Menso Jan Nubé,[1] Peter J. Blankestijn,[2] Pieter M. Ter Wee.[1] *[1]Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands.*

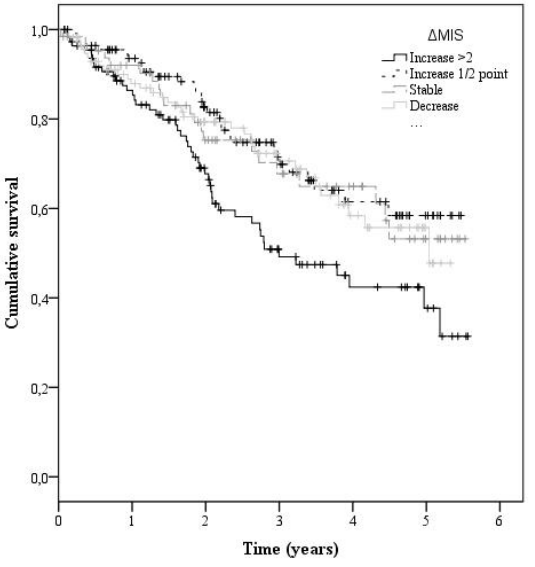
Background: protein-energy wasting, a state of decreased bodily protein and energy fuels, has been associated with increased mortality as measured by the Malnutrition Inflammation Score (MIS), a composite, clinical, nutrition-related score. Longitudinal data on this score, however, are limited. We checked whether a change in MIS over 1 year of follow-up is associated with mortality.

Methods: data from CONTRAST were used, a well-defined cohort of end-stage kidney disease patients. Patients were selected for analysis if MIS was available at baseline (M0) and at 12 months (M12). Delta (Δ) MIS was calculated as MIS (M12) – MIS (M0). As the

association between ΔMIS and mortality was not linear, patients were divided into quartiles of ΔMIS. Cox proportional hazards models, crude and adjusted for potential confounders, were used to calculate hazard ratios (HRs) of patients with severe deteriorating MIS (increase >2 points), mild deteriorating MIS (increase of 1 or 2 points), stable MIS versus patients with an improving MIS.

Results: 404 patients were available for analysis. Mean age was 63.0±13.5 and 62.4% were male. During follow-up (median 3.1 years), 135 patients died. Median ΔMIS was 1.0 (IQR -1.0 to 3.0). Survival curves are shown in fig 1. HR of patients with a mild deteriorating or stable MIS versus patients with an improving MIS was 0.85 (95%CI 0.53-1.39) and 0.97 (95%CI 0.56-1.67), respectively; for patients with a severe deteriorating MIS, HR was 1.63 (95%CI 1.02-2.51). After correction for age, sex, dialysis vintage and dialysis modality, this association did not remain significant (p>0.1).

Figure 1: survival curves of MIS change over 1 year



Conclusions: a change in MIS over 1 year is not associated with mortality in a multivariable survival analysis.

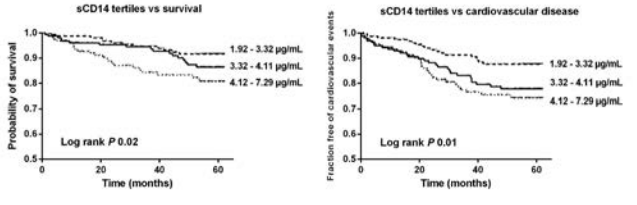
FR-PO858

Soluble CD14, a Marker of Endotoxemia, Associates with Survival and Cardiovascular Disease in CKD Patients Ruben Poesen,[1] Ian Barrows,[2] Ali Ramezani,[2] Pieter Evenepoel,[1] Kathleen Claes,[1] Bjorn Meijers,[1] Dominic S. Raj.[2] *[1]Nephrology, Univ Hospitals Leuven, Belgium; [2]Renal Diseases and Hypertension, George Washington Univ.*

Background: CKD goes along with gut microbial dysbiosis and gut barrier dysfunction, possibly contributing to endotoxin translocation. Subsequent binding of endotoxin to toll-like receptor-4 and its co-receptor CD14 activates the innate immune system. As half-life of systemic endotoxin is very short, soluble CD14 (sCD14) has been proposed as better marker of endotoxin exposure. Whether sCD14 relates to adverse outcome in CKD patients not yet on dialysis is unknown.

Methods: We performed a prospective study in CKD patients stage 1-5. Plasma sCD14 was determined with ELISA. Determinants of sCD14 were examined with regression analysis. The relationship between sCD14, survival and cardiovascular disease (CVD) was explored using Kaplan Meier and Cox PH analysis.

Results: 495 CKD patients were followed from 2005 until 2010. Median plasma sCD14 was 3.72µg/mL (IQR 3.15–4.40). Lower eGFR and higher CRP were the strongest determinants of higher sCD14 (both P<0.0001). During follow-up, we observed 53 deaths (Tertile 1/2/3: 12/17/24 events, log rank P 0.02, see figure). In Cox PH analysis, sCD14 remained a significant predictor of death (univariate HR per SD increase of 1.809 (1.356–2.413), P<0.0001), even after adjustment for renal function, Framingham risk factors, CRP and albumin (HR 1.899 (1.316–2.739), P 0.0006). We also noted 78 CV events (Tertile 1/2/3: 18/29/31 events, P 0.01, see figure). This association remained borderline significant in the fully adjusted model (HR 1.299 (0.999–1.689), P 0.05).



Conclusions: Plasma sCD14 is elevated in patients with advanced CKD, suggesting increased endotoxin exposure. sCD14 is independently associated with survival and CVD, pointing to a role of endotoxemia as driving force behind adverse outcome in CKD.

FR-PO859

Gut Microbiota Derived Trimethylamine-N-Oxide Is Not a Biomarker for Mortality and Cardiovascular Disease in European CKD Patients Ruben Poesen, Pieter Evenepoel, Bjorn Meijers. *Nephrology, Univ Hospitals Leuven, Belgium.*

Background: Trimethylamine-N-oxide (TMAO) is a gut microbiota derived metabolite of dietary choline, lecithin and l-carnitine with recent evidence suggesting involvement of TMAO in development of atherosclerosis. Recently, TMAO has been associated with mortality and cardiovascular disease in a general US population as well as in US CKD patients not yet on dialysis. As there may be population-specific differences in diet and/or microbial metabolism, we questioned whether TMAO also relates with adverse outcome in European CKD patients.

Methods: We performed a single-center prospective study in patients with CKD stage 1-5. Baseline serum levels of TMAO were determined using LC-MS. Correlation between eGFR and serum TMAO was explored using Spearman's rank correlation analysis. The relationship between TMAO, survival and cardiovascular disease was examined using Cox proportional hazard analysis.

Results: 488 CKD patients were followed from November 2005 until December 2010. Median serum level of TMAO was 11.6 µM (IQR 5.7 – 21.8). We observed a highly significant inverse correlation between eGFR and serum TMAO (rho 0.71, P < 0.0001). During follow-up, we noted a total of 51 deaths and 75 cardiovascular events. In univariate cox proportional hazard analysis, TMAO was a significant predictor of mortality (HR 1.521 (1.183 – 1.956), P 0.001) and cardiovascular disease (HR 1.570 (1.283 – 1.921), P < 0.0001). However, significance was lost after adjustment for eGFR for overall mortality (HR 1.126 (0.795 – 1.595), P 0.50), as well as for cardiovascular events (HR 1.256 (0.958 – 1.647), P 0.10).

Conclusions: Serum levels of TMAO rise in parallel to a declining renal function and further analysis of 24h urine samples is ongoing to elucidate its renal handling. In this European cohort of CKD patients, we were not able to find an association between TMAO and adverse outcome that is beyond renal function, which is in contrast to previous observations in US populations, both general and CKD. This may question the validity of TMAO as a universal biomarker for cardiovascular disease, possibly due to population-specific differences in diet and/or microbial metabolism.

FR-PO860

Microbiota Derived Phenylacetylglutamine Associates with Survival and Cardiovascular Disease in CKD Patients Ruben Poesen, Pieter Evenepoel, Bjorn Meijers. *Nephrology, Univ Hospitals Leuven, Belgium.*

Background: Lately, there is increasing interest in gut microbiota derived uremic retention solutes as driving force behind adverse outcome in CKD. Both p-cresyl sulfate and indoxyl sulfate are considered representatives of this group, also commonly referred as to protein-bound solutes due to their high protein binding and dependence on active tubular secretion for renal clearance. Phenylacetylglutamine is another microbial metabolite subjected to high tubular secretion, although protein binding is rather low. We questioned whether this solute also relates to adverse outcome in CKD patients not yet on dialysis.

Methods: We performed a prospective study in CKD patients stage 1-5. Serum levels of phenylacetylglutamine were determined using LC-MS. Correlation between eGFR and serum phenylacetylglutamine was explored using Spearman's rank correlation analysis. The relationship between phenylacetylglutamine, survival and cardiovascular disease (CVD) was examined using Kaplan Meier and Cox PH analysis.

Results: 488 CKD patients were followed from November 2005 until December 2010. Median serum level of phenylacetylglutamine was 6.2 µM (IQR 3.0–13.2). We observed a highly significant inverse correlation between eGFR and serum phenylacetylglutamine (rho -0.76, P<0.0001). During follow-up, we noted a total of 51 deaths and 75 CV events with a gradual and significant increase with higher tertiles of phenylacetylglutamine (both log rank P<0.0001). In univariate Cox PH analysis, phenylacetylglutamine was a significant predictor of mortality (HR 1.962 (1.481–2.598), P<0.0001) and CVD (HR 1.997 (1.590–2.508), P<0.0001), even after adjustment for renal function, Framingham risk factors, calcium-phosphorus-PTH, CRP and albumin (HR 1.611 (1.140–2.275), P 0.007 for mortality and HR 1.668 (1.295–2.149), P<0.0001 for CVD).

Conclusions: Serum levels of microbiota derived phenylacetylglutamine are elevated in patients with more advanced CKD. Serum phenylacetylglutamine is also a strong and independent risk factor for mortality and CVD. Further analysis of 24h urine samples is ongoing to differentiate between impact of higher urinary excretion as surrogate of intestinal generation vs. impact of lower tubular secretion.

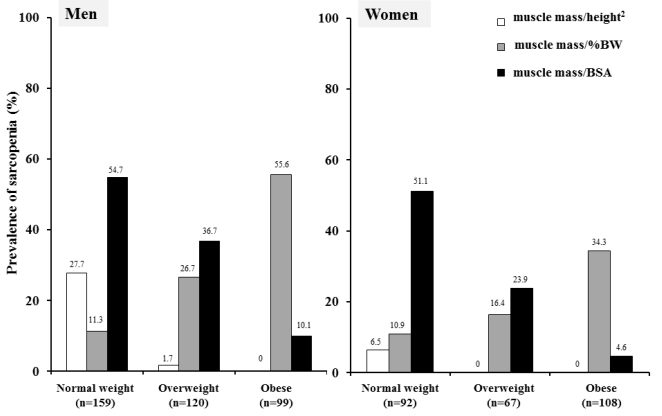
FR-PO861

Sarcopenia Among Prevalent Hemodialysis Patients: Weighing the Evidence
Piyawan Kittiskulnam,[1] Juan Jesus Carrero,[2] Glenn Matthew Chertow,[3] George A. Kaysen,[4] Kirsten L. Johansen.[1] *[1]UCSF; [2]Karolinska Inst; [3]Stanford Univ; [4]UC Davis.*

Background: There is no consensus on the best way to define sarcopenia in ESRD. Use of muscle/height^2(Ht^2) is suggested by geriatric societies but may underestimate sarcopenia, particularly in the setting of excess adiposity. We compared three definitions of sarcopenia in a prevalent HD cohort.

Methods: ACTIVE/ADIPOSE enrolled HD patients from San Francisco and Atlanta from 6/09 to 8/11. Bioelectrical impedance spectroscopy was performed before a midweek dialysis session (n=645), and total-body muscle mass was estimated using an equation containing age, sex, body weight (BW), and intracellular water. We defined sarcopenia as muscle mass ³2SD below sex-specific means for adults 18-49 y from NHANES data indexed to Ht^2, %BW, and body surface area (BSA) by DuBois formula. We compared the prevalence of low muscle mass among the three methods and assessed their correlation with handgrip strength.

Results: Mean age was 57±14 years, 41% were women, 61% black. The prevalence of sarcopenia was 8% by muscle/Ht^2, 25% by muscle/%BW and 32% by muscle/BSA. Most sarcopenic patients by muscle/BSA method had normal BMI, while >50% of sarcopenic patients by %BW were obese. Almost none of the overweight or obese patients were identified as sarcopenic by muscle/Ht^2.



Prevalence of sarcopenia by international classification by BMI.

Patients who were classified as sarcopenic by muscle mass/BSA but not Ht^2 had significantly higher BMI and %body fat than those who were sarcopenic by both methods (25.2 vs 21.3 kg/m^2,p<0.001 and 31.1 vs 24.4%,p<0.001, respectively). Handgrip strength was moderately correlated with muscle/BSA (r=0.6) but weakly correlated with muscle/Ht^2(r=0.3) and %BW (r=0.4).

Conclusions: Skeletal muscle mass normalized to Ht^2 may underestimate the prevalence of sarcopenia, particularly in overweight HD patients. Detection of sarcopenia among overweight/obese patients requires adjustment for body size or adiposity.

Does a Probiotic Supplementation Alter the Indoxyl Sulfate Levels in Non-Dialysis Chronic Kidney Disease Patients? A Randomized Placebo-Controlled Clinical Trial
Denise Mafra,[1] Natalia Alvarenga Borges,[1] Milena Barcza Stockler-Pinto,[2] Denis Fouque,[4] Amanda F. Barros.[2] *[1]Medical Sciences Graduate Program, Federal Univ Fluminense, Rio de Janeiro, Brazil; [2]Cardiovascular Sciences Graduate Program, Federal Univ Fluminense, Rio de Janeiro, RJ, Brazil; [3]Post Graduate Program in Dentistry, Estácio de Sá Univ, Rio de Janeiro, RJ, Brazil; [4]Dept of Nephrology, Centre Hopitalier Lyon Sud, Univ Claude Bernard, Lyon, France; [5]Graduate Program in Science Applied to Health Products, Federal Univ Fluminense, Rio de Janeiro, RJ, Brazil; [6]Medicine Faculty, Federal Univ Fluminense, Rio de Janeiro, RJ, Brazil.*

Background: The imbalance in gut microbiota associated with alterations in colonic epithelium contributes to the accumulation of gut-derived uremic toxins in chronic kidney disease (CKD) patients. Therapeutic strategies like probiotic supplementation may modulate the gut microbiota and reduce the toxins levels. To determine the effect of probiotics supplementation on indoxyl sulfate (IS) plasma levels in non-dialysis CKD patients.

Methods: In this double-blind, placebo-controlled trial, 29 non-dialysis CKD patients were recruited. Patients were randomized to receive probiotic (1 capsule, containing 30 billion of colony forming units - S. *thermophilus*, L. *acidophilus*, and B. *longum*, n= 17) or placebo (n= 12) for 3 months. IS plasma levels were quantified with HPLC, calprotectin and protein C reactive were analyzed by immunoenzymatic assay. Five patients in probiotic group and three in placebo were lost to follow-up.

Results: Plasma IS increased significantly in patients who received probiotics whereas the other parameters did not change.

Parameters	Probiotic (N=12)		Placebo (n=9)	
	Before	After 3 months	Before	After 3 months
Total IS (mg/L)	8.0 (0.1 - 99.5)	72.0 (6.1 - 240.0)*	5.5 (0.64 - 21.2)	15.8 (4.9 - 84.3)
Calprotectin (ng/dL)	12.8± 4.6	14.0± 6.5	12.2 ± 4.8	11.4 ± 3.1
CRP (mg/dL)	4.8 (1.3 - 6.1)	3.6 (1.2 - 6.0)	1.2 (0.4 - 3.7)	0.4 (0.4 - 6.8)

Conclusions: Data from this randomized study suggest that administration of probiotics alone may increase plasma IS levels in non-dialysis CKD patients. These findings support the need for more studies with probiotics in CKD patients.

Funding: Government Support - Non-U.S.

FR-PO863

Prevention of the Progression of Both Renal Dysfunction and the Atherosclerotic Change in Chronic Kidney Disease (CKD) Stage 3-4 Patients due to Benign Nephrosclerosis
Yoshihiko Inoue, Tomoaki Miyazaki, Shinya Omiya, Kiyoko Inui, Daisuke Komukai, Ashio Yoshimura. *Div of Nephrology, Showa Univ Fujigaoka Hospital, Yokohama, Kanagawa, Japan.*

Background: Effect of EPA for CKD patients is not fully known. We studied the efficacy of EPA to prevent the progression of both renal impairment and atherosclerosis in CKD stage 3-4 patients due to benign nephrosclerosis (BNS).

Methods: 31 CKD stage 3-4 patients due to BNS with dyslipidemia were followed for 3 years after the start of EPA treatment. The dosage of 1800 mg/day of EPA was newly prescribed. T-cho, LDL-cho, Triglycerides (TG), eGFR, the amount of proteinuria, EPA, arachidonic acid (AA), Dihomo-gamma-linolenic acid (DGLA) and docosa hexaenoic acid (DHA) were studied. Both right and left (RL) brachial-ankle pulse wave velocity (baPWV), RL maximum carotid intima-media thickness (max IMT), RL maximum carotid plaque thickness and RL ankle-brachial index (ABI) were evaluated at before treatment (baseline), after 1,2-year and at the end of the study (3-year).

Results: EPA, EPA/AA ratio, TG. RL baPWV, RL max IMT and eGFR showed significant improvement at 3-year (table 1).

	Baseline	End of the study (3-year)	P
EPA (μg/ml)	70.4±38.7	236.8±99.2	<0.01
EPA/AA	0.39±0.23	1.39±0.56	<0.01
TG (mg/dl)	243.8±127.0	136.7±37.3	<0.01
Right baPWV (cm/s)	1686.0±369.2	1580.3±289.4	<0.05
Left baPWV (cm/s)	1723.4±378.8	1618.2±245.0	<0.05
Right max IMT (mm)	0.96±0.35	0.79±0.26	<0.05
Left max IMT (mm)	0.92±0.31	0.76±0.24	<0.05
eGFR (ml/min/1.73m^2)	44.0±11.2	48.5±14.6	<0.05

Furthermore, both EPA and DHA levels were significantly low in eGFR exacerbation patients group (n=9) compared with the improvement group (n=22) at both baseline and 3-year. Patients showing the highest EPA levels at baseline (EPA: 124.6±18.8 mg/ml, n=8) showed significant improvement in both eGFR and baPWV compared with those with the lowest EPA levels (30.1±8.1 mg/ml, n=8). There was no difference on both plaque thickness and ABI between baseline and 3-year.

Conclusions: EPA powerfully prevents the progression of both renal dysfunction and the atherosclerotic change in CKD stage 3-4 patients due to BNS.

FR-PO864

Relationships Between Composition of Gut Microbiota and Uremic Toxins
Mami Kikuchi,[1] Ryoko Tateoka,[1] Yoshiharu Itoh,[1] Wataru Suda,[2,3] Masahira Hattori.[2,4] *[1]Kureha Corporation, Tokyo, Japan; [2]The Univ of Tokyo, Chiba, Japan; [3]Keio Univ, Tokyo, Japan; [4]Waseda Univesity, Tokyo, Japan.*

Background: Gut microbiota is known to function in producing uremic toxins (UTs) and their precursors, such as indoles, phenols and so on. However the relationships between specific bacteria and UTs are not clear. To elucidate the production of UTs by gut microbiota, we collected blood, urine and feces samples in normal rats, rats subjected to 5/6 renal removal. AST-120, a spherical carbon adsorbent of intestinal small-molecular-weight UTs and/or their precursors, was used to evaluate the effects of UTs on gut microbiota.

Methods: Serum and urine levels of UTs were quantified by SRM of LC/ESI-MS/MS. Gut microbiota from feces were analyzed using 454-pyrosequencing of a hypervariable V1-V2 region of the 16S rRNA gene in combination with barcode sequences. We used the GLSEARCH program and self-build 16S sequences database and genome database to determine the closest species. We identified the indole and/or phenol producing species using BLASTX.

Results: In CKD rats, urinary excretion and serum concentrations of UTs, such as indoxyl sulfate and phenyl sulfate, were higherthan control rats. In AST-120-administered CKD rats, urinary excretion and serum concentrations of UTs decreased compared to CKD

rats. The overall bacterial community composition was compared according to the UniFrac distance metric among control rats, CKD rats, and CKD + AST-120 rats. A principal coordinate analysis plot reveled clustering of each group. We identified the intestinal microbiome containing tryptophanase and/or tyrosine phenol-lyase gene in the genome sequences from NCBI bacterial genome. These enzymes metabolize tryptophan to indole and tyrosine to phenol, respectively.

Conclusions: Our data suggest that UT production is not only the cause of uremic symptoms but also correlated with a subset of indigenous gut microbes and affects the composition of gut microbiota.

FR-PO865

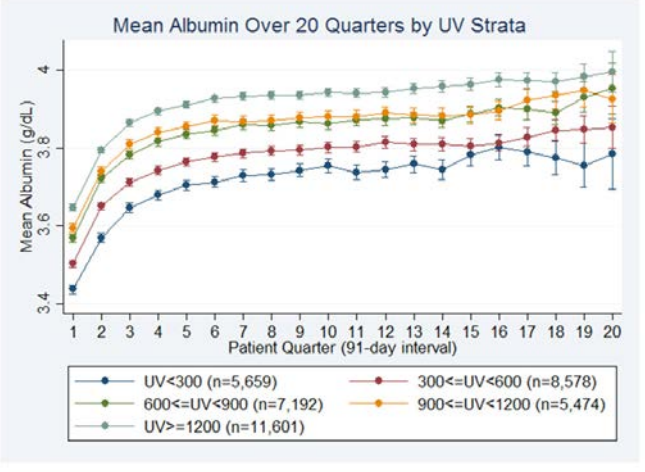
Association of Urine Volume at the Start of Dialysis and Subsequent Changes in Serum Albumin Level in Incident Hemodialysis Patients

Rieko Eriguchi,[1] Yoshitsugu Obi,[1] Connie Rhee,[1] Steven M. Brunelli,[2] Joline L.T. Chen,[1] Anna Mathew,[3] Tae Hee Kim,[1] Elani Streja,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]DaVita Clin Research; [3]Hofstra North Shore-LIJ Health System; [4]UTHSC.*

Background: Previous studies have shown that low serum albumin(Alb) levels are associated with higher mortality in hemodialysis (HD) patients. While serum Alb is a critical inflammatory and nutrional marker, low Alb may also result from albuminuria. It is unknown if a change in serum Alb over time is due to the loss of residual kidney function. While data on urine Alb was unavailable, we hypothesized that higher urine volume (UV) is associated with a decrease in Alb.

Methods: Among 38,504 incident HD patients receiving care from a large dialysis organization from 2007-2011, we examined serum albumin level trajectory over 5 years (divided into 20 patient quarters) across five strata of baseline UV: <300, 300-<600, 600-<900, 900-<1200, ³1200 mL. The association between baseline UV and serum albumin trend was examined using mixed effects models with adjustment for age, gender, race, diabetes, and insurance type.

Results: Patients were 62±15 years old, 38% female, 28% black, and 46% diabetic. Higher baseline UV was incrementally associated with higher Alb levels across strata: 3.44±0.48g/dL, 3.50±0.46g/dL, 3.57±0.44g/dL, 3.59±0.45g/dL, and 3.65±0.46g/dL, respectively.[Figure] Serum Alb increased over the first 6 patient quarters (18 months) on dialysis and then stabilized. Patients with higher UV not only had a higher baseline serum Alb level, but also maintained a higher serum Alb level over follow-up.



Conclusions: Higher baseline UV appears to be associated with sustained higher serum Alb levels over time. Improvement in hypoalbuminemia as a result of transition to dialysis therapy appears to be independent of residual kidney function and may suggest an inherent advantage of dialysis initiation.

FR-PO866

Individual Variation of Hippuric Acid and P-Cresyl Sulfate Plasma Levels Correlate with Variation of Intestinal Microbial Phylotypes in Hemodialysis Patients

Griet Lrl Glorieux,[1] Sara Vieira-Silva,[2] Sunny Eloot,[1] Eva Schepers,[1] Annemieke Dhondt,[1] Raymond C. Vanholder,[1] Jeroen Raes,[2] Geert Huys,[3] Marie Joossens.[2] *[1]Renal Div, Ghent Univ Hospital, Gent, Belgium; [2]Microbiology and Immunology, KULeuven, Leuven, Belgium; [3]Microbiology, Ghent Univ, Gent, Belgium.*

Background: In chronic kidney disease (CKD),a myriad of metabolites accumulate in the circulation. A substantial part is generated by intestinal microbiota. We hypothesize that there is a link between plasma levels of these uremic metabolites and the composition of the intestinal microbiota.

Methods: Over 4 months,up to 8 consecutive plasma and fecal samples from 16 hemodialysis patients (14M/2F;74±10y;vintage:43±30mo) were collected. Uremic metabolites were quantified by UPLC. Fecal microbial DNA was amplified for 16S rDNA (V4 hypervariable region) sequencing (Illumina MiSeq). After quality and chimera filtering (UCHIME),data was rarefied to 10,000 reads/sample and taxonomically annotated (RDP). Correlation between the maximum intra-patient variability of metabolite levels and the corresponding time-points of fecal microbial phylotypes was assessed. In addition, cross-sectional correlations at t0 were evaluated. Statistical analyses were performed with R package phyloseq,using Spearman correlation,with multiple testing correction (FDR) per metabolite for the number of genus-level phylotypes.

Results: Within this patient group,we observed a strong positive correlation between an increase in total hippuric acid and unclassified *Peptostreptococcaceae* (ρ=0.83;corrected p-value=0.012). We also found a positive trend for total p-cresyl sulfate and unclassified *Clostridiales* and unclassified *Ruminococcaceae* (ρ=0.77 and 0.74;corrected p-value=0.074 and 0.078,respectively). Cross-sectionally at t0,strong negative correlations between indoxyl sulfate, indole acetic acid and specific unclassified bacterial phylotypes (ρ=-0.79 and -0.84;corrected p-value=0.028 and 0.004) were observed.

Conclusions: There is a link between plasma levels of specific uremic metabolites and fecal bacterial phylotypes,suggesting that these microbiota might be a target for reducing uremic metabolite levels in patients with CKD. Data needs validation on larger patient groups.

Decreased Vitamin K Intake in Italian Hemodialysis Patients

Maria Fusaro,[1] Claudia D'Alessandro,[2] Marianna Noale,[1] Giovanni Tripepi,[4] Luciana Bonfante,[3] Nicola Veronese,[6] Irene Santinello,[3] Sabina Zambon,[5] Sandro Giannini,[5] Maurizio Gallieni,[6] Adamasco Cupisti.[2] *[1]CNR - Padua, Italy; [2]Div of Nephrology Dept of Clinical and Experimental Medicine, Univ of Pisa; [3]Nephrology Unit, Univ of Padua; [4]CNR-IFC Clin. Epid. and Physiopath. of Renal Dis. and Hypert. of Reggio Calabria; [5]Clinica Medica 1, Univ of Padua, Italy; [6]Univ of Padova; [7]Dialysis Unit St Carlo, Milan, Italy.*

Background: Vitamin K is involved in the production of Bone and Matrix Gla Proteins (BGP and MGP, respectively), regulating bone and vascular health. We carried out a pilot study to evaluatevitamin K intake in hemodialysis (HD) patients.

Methods: We measured vitamin K1 intake (7-day food record) in 78 italian hemodialysis patients (48 M, 30 F) compared to intake in 39 healthy adults (28 M, 11 F).

Results: HDpatients had a mean (± SD) age of 62.8±15.0 years, median dialytic age of 97 months, mean BMI of 25.4±4.5 Kg/m2. Mean serum levels of interest for CKD-MBD were: Ca 9 mg/dL, P 4.3 mg/dL, PTH 231.5 pg/mL, ALP 81.5 U/l. Control group mean age was 54.6±13.9 years. HD patients had a significantly lower intake of vitamin K1 compared to controls (*see Table*).We also evaluated and compared between HD patients and controls the intake of other fat soluble vitamins and of nutrients closely associated with bone and mineral disorders in CKD patients (*see table*). All were decreased in HD patients.

Data	Patients	Controls	p value
Vitamin K1 (mcg/day) [Median]	**70.1**	**109.2**	**0.0009**
Vitamin A (mcg/day) [Median]	306	495.0	<0.0001
Vitamin D (mcg/day) [Median]	1.2	1.74	0.0326
Active Vitamin E (mcg/day) [Median]	7.1	11.24	<0.0001
Calcium (mg/day) [Median]	364.5	587.8	<0.0001
Phosphorus (mg/day) [Median]	749.2	1079.2	<0.0001
Magnesium (mg/day) [Median]	144.9	212.7	<0.0001

Conclusions: This Vitamin K intake study is the first carried out on Italian diet. We found a decreased intake of Vitamin K1 in HD patients. This finding supports the hypothesis of supplementing vitamin K for the prevention of vascular calcifications and bone disorders in HD patients. Benefits of vitamin K supplementation should be proved by a randomized trial.

FR-PO868

Association of Geriatric Nutrition Risk Index with Body Fluid Composition, Renal Adverse Outcomes and Mortality in Patients with Chronic Kidney Disease

Reibin Tai, Yasushi Ohashi, Toshiyuki Aoki, Shizuka Kobayashi, Atsushi Aikawa, Ken Sakai. *Dept of Nephrology, School of Medicine, Faculty of Medicine, Toho Univ, Tokyo, Japan.*

Background: Decreased body stores of protein and energy fuels may express by the geriatric nutritional risk index (GNRI) consisting of body mass index (BMI) and serum albumin levels. We studied the association of the GNRI with body fluid composition, renal adverse outcomes and all-cause mortality in patients with chronic kidney disease (CKD).

Methods: Body fluid composition was measured in 306 patients with CKD from 2005 to 2014 and was separated into three components – (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW) content, and (c) extracellular water (ECW) content. Patients were categorized according to tertiles of GNRI levels. Of those, 275 patients were followed until March 2015. The adverse renal outcomes were defined by a decline of 50% or more from baseline glomerular filtration rate or initiation of renal replacement therapy.

Results: Patients with the lower tertiles of the GNRI levels were more likely to be higher age, have a lower BMI, diastolic blood pressure, serum albumin, hemoglobin, glomerular filtration rate, and proteinuria ($P < 0.05$). In the body fluid composition, those tended to have lower free water mass ($r = 0.73$, $P < 0.001$) and the ratio of extracellular water to

intracellular water ($r = 0.37$, $P < 0.001$). Compared with patients with the middle tertile of the GNRI levels during a median 2.5-year follow-up, the lowest tertile of the GNRI levels had higher mortality (6.8 vs. 1.7 per 100 patient-years, $P < 0.001$), but had no worse adverse renal outcomes (16.5 vs. 9.0 per 100 patient-years, $P = 0.08$). In multivariate analysis, the lower GNRI levels independently remained as a risk factor for all-cause mortality (hazard ratio, 3.16; 95% CI, 1.30–8.84; $P < 0.001$).

Conclusions: The GNRI may be a simple and useful tool for predicting the risk of mortality even in CKD population including patients with massive proteinuria. These findings emphasize the importance of adequate body stores of protein and energy fuels in patients with CKD.

FR-PO869

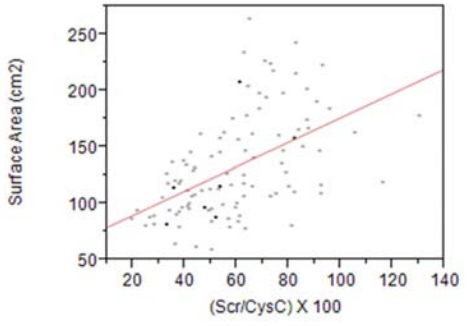
A Novel Index for Estimation of Muscle Mass Using Biomarkers of Kidney Function: Sarcopenia Index

Kianoush Banaei-Kashani,[1,2] Lucie Kukralova,[3] Erin N. Frazee,[4] Rahul Kashyap.[2] *[1]Div of Nephrology and Hypertension, Dept of Internal Medicine, Mayo Clinic, Rochester, MN; [2]Div of Pulmonary and Critical Care, Dept of Internal Medicine, Mayo Clinic, Rochester, MN; [3]Faculty of Medicine in Hradec Kralove, Charles Univ, Prague, Czech Republic; [4]Dept of Pharmacy, Mayo Clinic, Rochester, MN.*

Background: Sarcopenia is associated with poor patients' outcomes in Intensive Care Unit (ICU). Tools to evaluate sarcopenia are DXA scan, CT and MRI, which may not be feasible for critically ill patients. We hypothesize a novel index which can be used as a surrogate for sarcopenia among ICU patients.

Methods: This is a secondary analysis of prospectively enrolled critically ill patients. Adult ICU patients (>18 years) with shock, sepsis, use of IV antibiotics and contrast media exposure, in 24 hours of enrollment, intra-abdominal hypertension or severe Trauma were included. We excluded patients with pre-existing acute kidney injury, pregnancy, and kidney transplant, or those who were on dialysis or were moribund. We measures paraspinal muscle surface area at L3 level, using Slice-O-Matic software (TomoVision®,Magog, Canada). Sarcopenia Index (SI) was calculated as [Serum Creatinine (Scr) ÷ Cystatin C (CysC)] X 100.

Results: A total of 226 patients met the inclusion criteria. Among these enrollees, 110 patients who had abdominal CT within ± 4 weeks of their index ICU admission were included in the final analysis. The median age (IQR) was 67 (57-77) years and 59 (54%) were male. SI and Paraspinal Muscle Surface Area were found to be statistically correlated ($R^2 = 0.26$, p<.0001).



Conclusions: SI has a fair correlation with gold standard in critically ill patients. This index would be a surrogate for sarcopenia for patients who cannot tolerate transfer to imaging testing.

FR-PO870

Association with Activities of Daily Living and Geriatric Nutritional Risk Index Improves the Prediction of Mortality in Patients on Hemodialysis

Kaoru Yasuda,[1] Shoichi Maruyama,[2] Kunio Morozumi.[1] *[1]Nephrology, Masuko Memorial Hospital, Nagoya, Aichi, Japan; [2]Nephrology, Nagoya Univ, Nagoya, Aichi, Japan.*

Background: Protein energy wasting (PEW) is a typical status of Malnutrition seems to be a prevalent complication in end-stage renal disease (ESRD), and is associated with poor prognosis. We previously reported that Geriatric Nutritional Risk Index (GNRI) is useful marker for the assessment of malnutrition status in hemodialysis (HD) patients. However the interaction between actual activities of daily living(ADL) and GNRI is uncertain. We investigated the prognostic value of the ADL and GNRI, and hypothesized that the combination of both indicators could improve predictive values for mortality in HD patients.

Methods: A total of 304 stable HD patients were enrolled. They were divided into tertiles according to the ADL defined by the Renal Data Registry of Japanese Society for Dialysis Therapy; tertile A: < independence, B: care-needed (mild) and C: care-needed (moderate or severe). They were also divided into tertiles of GNRI levels; L: <91.7, M: 91.7-97.8 and H: >97.8, and GNRI were 95.9±7.6,94.9±5.8,87.1±11.0in A, B and C of ADL, respectively (p<0.0001 in both).

Results: During the follow-up period (40 month), 59 patients were died (19.4%). Kaplan-Meier survival rates for 4 years were 88.9%, 82.1% and 53.1% in A, B and C of ADL, and were 63.5%, 82.8% and 88.8% in L, M and H of GNRI, respectively (p<0.0001 in both). The adjusted HR for mortality was 3.21 (95% CI, 1.57-6.95, p=0.0006, C vs A) and 3.24 (95% CI, 1.62-7.06, p=0.0019, L vs H). In the combined setting of ADL and GNRI with 9 groups (3x3), the risk of mortality was 8.02-fold (95%CI 2.56-35.4, p=0.0001, C+L vs A+H).

Conclusions: ADL and GNRI could strongly predict the mortality, and combination of both setting also improved the prediction of mortality with ESRD patient on HD.

	Univariate		Multivariate	
	HR (95%CI)	P value	HR (95%CI)	P value
Life activity (vs. A)		<0.0001		0.0006
B	1.69 (0.82-3.60)	0.15	1.15 (0.54-2.51)	0.71
C	5.80 (3.02-11.8)	<0.0001	3.21 (1.57-6.95)	0.0012
GNRI (vs. >97.9)		<0.0001		0.0019
91.7-97.9	2.31 (1.29-4.32)	0.0042	1.65 (0.75-3.79)	0.21
<91.7	3.99 (2.04-8.54)	<0.0001	3.24 (1.62-7.05)	0.0006

FR-PO871

Delta Neutrophil Index Is a Predictive Marker of Disease Severity in Patients with Acute Pyelonephritis

Sul A Lee,[1] Jong Hyun Jhee,[1] Jae Eun Um,[2] Meiyan Wu,[2] Hyung Jung Oh,[1] Jung Tak Park,[1] Seung Hyeok Han,[1] Shin-Wook Kang,[1,2] Tae-Hyun Yoo.[1] *[1]Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; [2]Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea.*

Background: Delta neutrophil index (DNI) is the fraction of immature granulocytes provided by a complete blood count analyzer. Previous studies demonstrated that DNI was a novel marker to predict clinical outcomes in sepsis patients. Therefore, this study was aimed to evaluate DNI as a predictive marker of disease severity in patients with acute pyelonephritis (APN).

Methods: Patients who were diagnosed with APN at Severance Hospital from December 2009 to July 2012 were retrospectively investigated. DNI levels were measured at the time of admission. Patients were classified into two groups according to the median value of DNI. Severe APN was defined as one or more of following conditions; bacteremia, acute kidney injury, hypotension requiring use of vasopressors, and admission of intensive care unit. Independent risk factors for severe APN were determined by multivariate logistic regression analysis. Area under the receiver operating characteristic curves (AUC) was compared among DNI, white blood cell (WBC) count, and C-reactive protein (CRP).

Results: A total of 258 patients were included in this study. The median age was 61.0 (19.0 – 87.0) years, and 237 patients (91.9%) were female. The median DNI levels were 2.5%. Severe APN was significantly more prevalent in the high DNI group. Multivariate analysis showed that DNI independently predicted severe APN (per 1% increase, odds ratio=1.287, 95% confidence interval=1.135-1.458, P<0.001). Furthermore, DNI was a better predictive marker of severe APN than WBC count [AUC (95% confidence interval); 0.697 (0.637-0.753) vs. 0.562 (0.499-0.624), P=0.001] and not inferior to CRP levels [0.697 (0.637-0.753) vs. 0.633 (0.571-0.692), P=0.118].

Conclusions: DNI at admission could be a valuable predictor of disease severity in patients with APN.

FR-PO872

An Improved Magnesium Formulation for Mitigating Cisplatin-Induced Renal Epithelial Cell Injury

Malvika H. Solanki,[1,2,3] Rachel Lauren Mintz,[2] Xiangying Xue,[2] Prodyot K. Chatterjee,[2] Christine N. Metz.[1,2,3] *[1]Elmezzi Graduate School of Molecular Medicine, NY; [2]Feinstein Inst for Medical Research, NY; [3]Hofstra-North Shore-LIJ School of Medicine, NY.*

Background: Cisplatin is a potent chemotherapy for treating cancer. It causes nephrotoxicity in ~25% and hypomagnesemia in ~90% patients. This hypomagnesemia is treated with oral magnesium (Mg) chloride ($MgCl_2$) and/or i.v. Mg sulfate ($MgSO_4$). Poor Mg intake and Mg deficiency are not uncommon in the US. Our previous studies revealed the beneficial effects of $MgSO_4$ in reducing cisplatin-induced acute kidney injury (AKI) (Solanki et al, *AJP Renal* 2014). This study compared the efficacy of various Mg formulations in reducing cisplatin-induced renal epithelial cell injury.

Methods: LLC-PK_1 renal epithelial cells were maintained in media containing 100%Mg (i.e. the amount of Mg found in growth media) or 10%Mg (Mg-deficient) for 3 days. To mimic Mg replacement, the 10%Mg cells were restored to 100%Mg using: $MgSO_4$, Mg-L-threonate (MgT), $MgCl_2$, and Mg gluconate (MgG) (keeping elemental Mg equal) and then treated with vehicle or cisplatin. Oxidative stress, cytotoxicity and inflammation were measured by DCF-DA assay, MTT assay and TNFα production, respectively. ERK activation was measured by in-cell-western.

Results: Cisplatin-induced oxidative stress, cytotoxicity, and inflammation were exacerbated by Mg deficiency, while Mg supplementation with all formulations consistently and significantly attenuated these effects. MgT was the most effective Mg-formulation for reducing cisplatin-induced oxidative stress and inflammation. Mechanistic studies revealed that cisplatin-induced ERK activation was modulated by Mg status and MgT was most protective.

Conclusions: Mg supplementation protected against cisplatin-induced oxidative stress, cytotoxicity and inflammation in renal epithelial cells. This is the first study to reveal the effectiveness of MgT over other Mg-formulations in reducing cisplatin-induced renal

epithelial cytotoxicity. Note: MgT has significantly lower GI-effects (bloating and diarrhea) than other Mg formulations. These results warrant further in vivo and clinical studies to investigate the beneficial role of MgT in protecting against cisplatin-AKI.

FR-PO873

Impact of Uremic Serum on the Barrier Function and Inflammation in Human Colonocytes Laila Santos Andrade,[1] Maria Dalboni,[2] Jose Tarcisio Giffoni,[2] Caren Cristina Grabulosa,[2] Lilian Cuppari.[1,2] *[1]Nutrition Graduation Program, Federal Univ of São Paulo, São Paulo, Brazil; [2]Medicine, Div of Nephrology, Federal Univ of São Paulo, São Paulo, Brazil.*

Background: In chronic kidney disease (CKD) it has been suggested that alterations of the gut are associated with inflammatory state and uremic toxicity. Studies suggest that uremia may impair the intestinal barrier function, by promoting increased intestinal permeability. In this study we aimed to evaluate the in vitro effect of uremic serum on the transepithelial electrical resistance (TER), inflammation and apoptosis in the intestinal epithelial cells.

Methods: Pools of serum were prepared from blood samples from patients maintained on hemodialysis (Pre-HD and Post-HD), and of patients with CKD stage 4 (NND-CKD). A pool of serum form healthy individuals served as control (CTL). When the TER exceeding 1,000 Ω /cm² was reached, the T84 cells were incubated for 24 h in medium containing 10% pool of serum from each group. At the conclusion of the incubation period, the TER was measured again and the following parameters were determined by flow cytometry: expression of toll-like receptor (TLR), production of reactive oxygen species (ROS) and apoptosis. TNF-α and IL-6 in the culture supernatant was determined by ELISA. A total of nine experiments were performed.

Results: No differences among groups were found regarding TER (p= 0.443), apoptosis (p= 0.751), ROS (p= 0.999), expression of TLR-2 (p= 0.493), TLR-4 (p= 0.418) and TLR-9 (p= 0.937) and secretion of TNF-α (p= 0.438). IL-6 secretion was higher (p<0.001) by cells incubated with post-HD pool (2.07±0,93pg/ml) when compared with cells incubated with CTL pool (0.67±0.35), NND-CKD (0.61±0.53) and pre-HD (0.11±0.45).

Conclusions: The results obtained from this model suggest that uremic serum *per se* does not seem to impair the integrity of intestinal epithelial cells. The increased IL-6 secretion in post-HD condition may be a consequence of pro-inflammatory stimulus of the dialysis process.

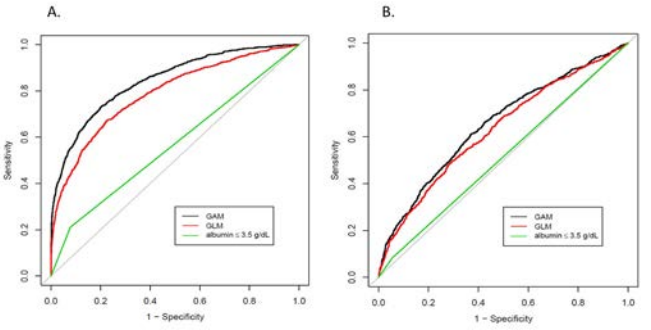
FR-PO874

Prediction of One-Year Mortality and Hospitalization Risk Using Nutritional Indicators and Their Trajectories in a Large Prevalent Hemodialysis Cohort Michelle M.Y. Wong,[1] Stephan Thijssen,[1] Yuedong Wang,[2] Len A. Usvyat,[3] Qingqing Xiao,[1] Peter Kotanko,[1] Franklin W. Maddux.[3] *[1]Renal Research Inst; [2]Univ of California - Santa Barbara; [3]Fresenius Medical Care North America.*

Background: Existing nutritional scores developed in the hemodialysis (HD) population do not consider temporal trajectories of nutritional parameters. We aimed to develop predictive models for mortality and hospitalization using readily available nutritional indicators and their rates of change.

Methods: Using retrospective data from a large US HD provider, a cohort with HD vintage ³1 year (N=21,082 and N=23,384 in mortality and hospitalization analyses, respectively) was randomly split 2:1:1 for model development, testing and validation. Parameters included demographics, nutritional/inflammation parameters, and slopes of all continuous variables over 6 months. Follow-up period was January-December 2012. Performance of generalized linear models and generalized additive models (GAM) was evaluated with area-under-the-curve (AUC), sensitivity and specificity.

Results: For both mortality and hospitalization prediction, GAM performed best. The best mortality model included neutrophil:lymphocyte ratio (NLR) slope, serum bicarbonate slope, albumin, creatinine, age, sex and vintage (AUC 0.85, 95% CI 0.83-0.86; sensitivity 0.70; specificity 0.83). The best hospitalization model included NLR slope, albumin, congestive heart failure, serum bicarbonate slope, creatinine, serum phosphate slope, vintage, diabetes, serum phosphate, volume of urea distribution, age and enPCR (AUC 0.70, 95% CI 0.62-0.79; sensitivity 0.41; specificity 0.88).



Receiver-operator characteristic curves for A) mortality and B) hospitalization models. Predictive performances of generalized additive models (GAM) (black line), generalized linear models (GLM) (red line), and albumin ≤3.5 g/dl alone (green line) are shown.

Conclusions: We developed novel and accurate predictive models for mortality and hospitalization using nutritional indicators and their slopes over time. Future studies are needed to assess if its application can improve nutritional intervention allocation and outcomes in HD patients.

Funding: Pharmaceutical Company Support - Renal Research Institute

FR-PO875

Extracellular Fluid/Intracellular Fluid (ECF/ICF) Volume Ratio Is a Novel Risk Indicator of Death and Highly Related to Malnutrition-Inflammation-Arteriosclerosis (MIA) Complex in Hemodialysis (HD) Patients Eunjung Kim, Soyon Rhee, Jiwon Ryu, Hee Jung Jeon, Jung-woo Noh, Ja-Ryong Koo. *Nephrology, Hallym Univ Hospital, Dongtan/Seoul, Korea.*

Background: Fluid overload and malnutrition are well recognized risk factors contributing to the high mortality in HD patients. Recent studies suggest pathophysiological link between fluid overload and malnutrition as a part of MIA complex. Because the ECF and ICF volume can represent fluid volume and nutritional status respectively, ECF/ICF ratio could be defined as a novel integrated marker reflecting both fluid overload and malnutrition. Accordingly we investigated the relationship of ECF/ICF ratio to survival in the context of MIA complex in chronic HD patients.

Methods: 77 HD patients (age 53±13 year, diabetes 38%) were prospectively enrolled. ECF/ICF volume was measured by multi-frequency bioimpedance analysis. Nutrition, inflammation, arteriosclerosis and volume status were measured by serum albumin, C-reactive protein (CRP), pulse wave velocity (PWV) and serum B-type natriuretic peptide(BNP) respectively.

Results: Mean ECF/ICF ratio was 0.56±0.06 and cut-off value for maximum discrimination of survival was 0.57 by ROC curve. As compared with low ECF/ICF group (ratio<0.57, 58%), high ECF/ICF group (ratio³0.57, 42%) had higher all-cause mortality, CRP, PWV, BNP and lower serum albumin level. During the 5-year follow-up, 24 all-cause death occurred (18 in high ECF/ICF group versus 6 in low ECF/ICF group, log rank P<0.001). In Cox analysis adjusted for age, diabetes, BP and cardiac function, the ECF/ICF ratio was an independent predictors of all-cause death (HR=1.25, 95% CI=1.10-1.54, per Δ0.01 in ECF/ICF ratio) and nullify the effect of MIA component and volume marker on survival. The degree of malnutrition (albumin), inflammation (CRP), arteriosclerosis (PWV) and fluid overload (BNP) were correlated well with ECF/ICF ratio.

Conclusions: Chronic HD patient with high ECF/ICF ratio is not only fluid overloaded but malnourished and have stiff artery with more inflammation. As a novel integrated marker of fluid overload and malnutrition, ECF/ICF ratio is highly related to MIA complex and a major risk indicator of death in chronic HD patients.

FR-PO876

Weight Gain After Listing Independently Predicts Pre-Transplant Sensitization Status Pritika Shrivastava,[1] Krista L. Lentine,[2] Ankit Sakhuja,[1] Fidel Barrantes,[3] Diane M. Cibrik,[1] Yihung Huang,[1] Abhijit S. Naik.[1] *[1]Univ of Michigan; [2]Saint Louis Univ; [3]Renal Medical Associates, NM.*

Background: Non-alloimmune stimuli such as infections, vaccinations and pro-inflammatory events cause sensitization to HLA antibodies and increased panel reactive antibodies. Obesity is recognized as an inflammatory state. Given relationship between obesity and inflammation we speculated that weight gain on the waitlist may increase sensitization status at the time of transplantation.

Methods: Using national data from the Organ Procurement and Transplantation Network we identified first time kidney only transplant recipients, aged 18-70, transplanted between January 1,2009 and June 30,2013.Previous non-renal transplants were excluded. A calculated panel reactive antibody of 20 % or more at the time of transplant was considered to be "sensitized". Using *a priori* chosen variables we performed a logistic regression model with sensitized status at time of transplantation as the dependent variable and change in BMI from listing to transplantation, BMI at transplant, recipient age, prior transfusion status, prior pregnancy, dialysis time and race as independent variables.

Results: Among 55,894 patients transplant recipients. 39.45 % were female of which 67.33 % were previously pregnant. Overall 15.12 % had received prior blood transfusions. Mean BMI at wait listing and transplantation was similar at 28.4± 5.5 kg/m^2. Greater than 50 % patients with BMI ≥ 30 kg/m^2 at listing had an increased their BMI by time of transplantation,while >50 % patients in BMI<30 kg/m^2 had lost weight. A 1-unit increase in BMI (kg/m^2) after transplantation was associated with an increased risk of being sensitized, aOR:1.01 (1.01-1.02). Other independent predictors included prior transfusion aOR:1.25 (1.18-1.33), AA race aOR:1.26 (1.19-1.32), pregnancy aOR:3.32 (3.04-3.63), dialysis time aOR:1.23 (1.11-1.14).

Conclusions: The majority of obese patients gain weight on the waitlist. We identified weight gain on the waiting list to be associated with a small but statistically significant increase in odds of being sensitized. Further studies are needed to determine the impact of malnutrition-inflammation complex on pretransplant sensitization.

FR-PO877

High Salt Diet Impairs the Immune Defense against Uropathogenic *Escherichia coli* in Murine Pyelonephritis Katarzyna Jobin, Katharina Hochheiser, Maike Giesing, Christian Kurts. *Inst of Experimental Immunology, Univ of Bonn, Bonn, Germany.*

Background: Recent studies demonstrated that NaCl stimulates immune responses, for example by promoting Th17 cells differentiation, macrophage recruitment into tissues and pro-inflammatory cytokine release from epithelial cell lines. Specially, high salt diet (HSD) exacerbated experimental autoimmune encephalomyelitis and improved immune defense against *L. major* infection. Little is known about the influence of HSD on anti-microbial responses in the kidney – an organ with extremely high sodium chloride concentration.

Methods: Wild type female mice were given normal salt diet (NSD) or HSD one week prior to infection with uropathogenic E. coli into the bladder resulting in pyelonephritis development. 20 h after the infection, kidneys were harvested and analyzed for CFU and immune cell subsets by flow cytometry.

Results: HSD exacerbated pyelonephritis as measured by CFU. Additionally, in kidney medullas of mice fed HSD the number of PMNs, Ly6c^{hi} macrophages and NK cells was significantly decreased in comparison with NSD fed mice. Although PMNs from mice given HSD produced more ROS than PMNs from mice on NSD, in vitro studies demonstrated that less medullary PMNs from mice fed HSD than NSD were able to perform phagocytosis.

Conclusions: Contrary to the expectations, HSD worsened experimental pyelonephritis, possibly through affecting immune cell activation and/or migration into the kidney medulla. This finding may be of clinical significance and, if confirmed in human studies, decreasing salt intake during bladder infection or pyelonephritis could support antibiotic therapy. Further studies are needed to elucidate the immune mechanisms underlying the negative effect of HSD on pyelonephritis.

Gut Microbiota *Lactobacillus* Protects against the Progression of Renal Impairment Through the Modulation of TLR2-Mediated Gut Barrier Stability in Rats Ayumi Yoshifuji, Shu Wakino, Junichiro Irie, Takaya Tajima, Kazuhiro Hasegawa, Hirobumi Tokuyama, Hiroshi Itoh. *Keio Univ, Japan.*

Background: Gut microbiota has been shown to have some role in the pathogenesis of various diseases and previous study demonstrated that *Lactobacillus*(*Lact*) decreased in number in CKD. In this study, we elucidated the significance of *Lact* in the pathogenesis of CKD.

Methods: Six-week-old spontaneously hypertensive rats (SHR) were rendered CKD by 5/6th nephrectomy (Nx). The SHRs were divided into three groups; sham-operated SHR (SHR), SHR with Nx (Nx) and Nx given *Lact* (Nx+*Lact*). After 12 weeks, biochemical parameters, urinary protein excretion, IL-6, histological changes in the kidney, and molecular changes of tight junctions and TLR2 expression were explored. Furthermore, concentrations of fecal uremic toxins were measured. To confirm the effect of *Lact*, rats are administered with broad antibiotics as pseudogerm-free condition and kept for 8 weeks with *Lact*. Human colon cell line, Caco-2 cells were treated with uremic toxin precursor, indole in the presence or absence of *Lact* or OxPAPC, an inhibitor of toll-like receptor, putative receptor recognizing *Lact*. The expressions of colon tight junction proteins were examined by immunoblotting.

Results: The gut flora analysis revealed that the decrease in *Lact* in Nx, which was restored in Nx+*Lact*. However, fecal uremic toxins did not show significant changes. Both serum indoxylsulfate and IL-6 increased in Nx. These increases were ameliorated in Nx+*Lact*. The decreases in the tight junction proteins Occludin and Zo-1 as well as in TLR2 in Nx were mitigated by *Lact*. In the pseudogerm-free condition, *Lact* decreased the urinary protein excretion. In Caco-2 cells, the downregulations of Occludin and ZO-1 by indole were ameliorated by *Lact*. OxPAPC inhibited the *Lact*-induced restoration of these tight junctions.

Conclusions: The supplementation of *Lact* improves the gut environment through the activation of TLR2 pathway. This improvement would contribute to the decrease in systemic uremic toxin levels, systemic inflammation and urinary protein excretion. This probiotic therapy can provide novel therapeutic strategy against the progression of CKD.

FR-PO879

Relationship Between Serum Uric Acid Change and Renal Injuries: An Observational Cohort Research from Pinggu District, Beijing Xiaohong Fan, Wenling Ye, Jianfang Cai, Jie Ma, Ying Sun, Xuewang Li, Xuemei Li. *Dept of Nephrology, Peking Union Medical College Hospital.*

Background: Hyperuricemia is thought to be a risk factor of CKD and ESRD. This research aims to demonstrate the relationship between serum uric acid change (ΔUA)based upon baseline from general population and indexes of renal injuries.

Methods: This cohort research was based on 5 years' follow up of an epidemiological studyin 2008 in Pinggu District, Beijing. Baseline population was 7086, and 5364 subjects were followed up in 2014. All subjects were interviewed with questionnaires, tests of anthropometric indicators, blood and urine sample collection. Serum creatinine, cystatin C, etc were tested. Urine sample was used to test ACR, α1mG, and NAG. Hyperurincemia is defined as serum uric acid is above 420mmol/L for men, and above 360mmol/L for women. According to baseline of 2008 and blood uric acid level of 2014 (Normal, N; High, H), patients were grouped as: N/N, H/N, N/H, H/H(group1-4). One-way ANOVA was applied to evaluate differences of indexes among all groups. Risk factors of CKD (ACR³3.39mg/mmol & eGFR<60ml/min/1.73^2)were evaluated with Multiple Logistic regression analysis.

Results: 1. 5364 patients(M:F 1:1.1)were included. In 2008 prevalence of hyperurincemia was 5.9%(7.0% for men, 5.0% for women), and Prevalence of hyperurincemia was 6.2%(8.5% for men, 4.2% for women)in 2014. 2.ΔeGFR of group N/H,H/H were significantly higher than that of group N/N,H/N, indicating that GFR of hyperurincemia patients following up in 2014 declined more than that of patients without hyperurincemia; serum cystatin C in 2014 increased significantly from group 1 to group 4; there was no significant difference among all groups inα1mG,NAG/Cr. 3. ΔUA, age, BMI, hypertension, DM were independent risk factors of CKD. HR of CKD in group N/H,H/H was 1.87 times(95%CI 1.30-2.68, P=0.001) and 4.2 (95%CI 2.60-6.70, P<0.001) times of group N/N.

Conclusions: In general population, elevation of serum uric acid is the independent risk factor of GFR decline and serum cystatin C ascent. It is also the independent risk factor of the development of CKD, and the decline of uric acid in the blood may reduce the risk of renal injuries.

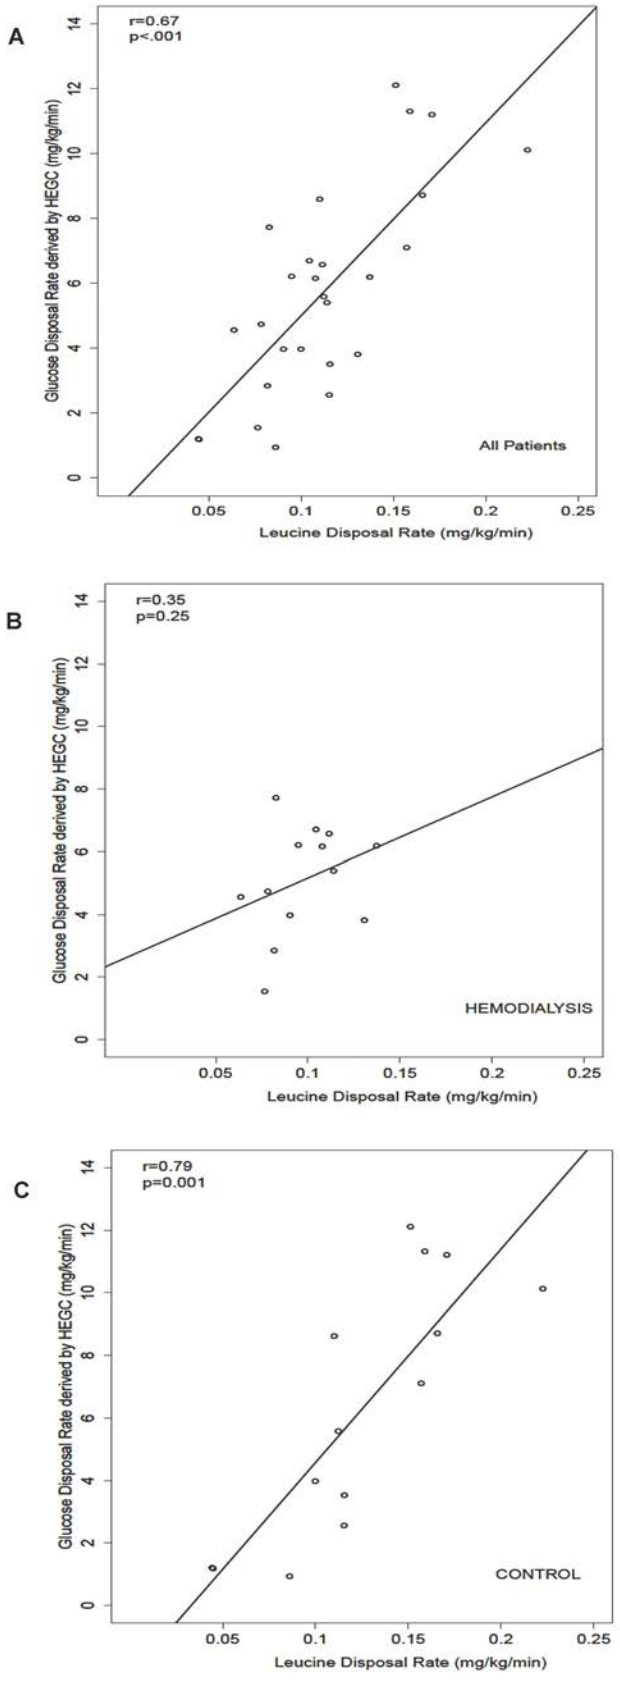
Leucine Disposal Rate for Assessment of Amino Acid Metabolism in Maintenance Hemodialysis Patients Gerald Denny,[1] Serpil Muge Deger,[1,2] Feng Sha,[1] Cindy Booker,[1,2] Charles D. Ellis,[1] Talat Alp Ikizler.[1,2] *[1]Nephroloy, Vanderbilt Univ, TN; [2]Veteran Affairs, TN.*

Background: Protein energy wasting (PEW) is common in patients undergoing maintenance hemodialysis (MHD) and is closely associated with poor outcomes. Insulin resistance and associated alterations in amino acid metabolism is a potential pathway leading to PEW. In this study we hypothesized that measurement of leucine disposal rate (LDR) during a hyperinsulinemic-euglycemic-euaminoacidemic clamp (HEAC) procedure would accurately measure the sensitivity of insulin for its actions on concomitant carbohydrate and protein metabolism in MHD patients.

Methods: We examined 15 MHD (aged 52±13 years, BMI 29± 5 kg/m$^{2)}$ patients and 16 control subjects (aged 46±10 years and BMI 28±7 kg/m$^{2)}$ by hyperinsulinemic euglycemic clamp (HEGC) procedure followed by HEAC clamp procedure to obtain glucose disposal rate (GDR) and LDR, respectively.

Results: The GDR by HEGC was 4.9±1.9 mg/kg/min in the MHD subjects compared to 6.3±4.1 mg/kg/min in the controls (P=0.47). The LDR during HEAC was 0.09±0.03 mg/kg/min for MHD patients vs 0.12±0.05 mg/kg/min for control (P=0.11). The GDR derived by HEGC and LDR correlated well in the control population (r=0.793, P=0.001), but less so in the MHD subjects (r=0.346, P=0.25).



Conclusions: Leucine disposal rate reliably measures amino acid utilization in MHD patients. The lack of correlation between GDR versus LDR in MHD subjects requires further investigation for understanding the effects of insulin signaling on protein metabolism in MHD patients.

FR-PO881

Age and Dependence on Dialysis Are More Important Predictors of Immune Response to Influenza Vaccine Than Inflammation and Iron Status

Jaromir Eiselt,[1] Lukas Kielberger,[1] Daniel Rajdl,[2] Jaroslav Racek.[2] *[1]Internal Dept 1, Charles Univ, Plzen, Czech Republic; [2]Dept of Biochemistry, Charles Univ, Plzen, Czech Republic.*

Background: The immune response to influenza vaccine is not uniform and may be influenced by many factors, e.g. comorbidities, age, inflammation or iron metabolism. The aim of our study was to identify factors associated with low production of hemagglutination-inhibition antibodies (HIA) after vaccination in hemodialysis (HD) patients and controls.

Methods: We evaluated the immune response to the influenza vaccine in a total of 122 stable HD patients and in 37 subjects without renal dysfunction. To identify factors associated with immune response, a stepwise backward and forward algorithm for a linear regression model was used with postvaccination increase in HIA titre against H1N1 vaccine strain as dependent variable and following independent variables: age, dependence on dialysis, diabetes, iron, transferrin, transferrin saturation, ferritin, hepcidin, interleukin-6, C-reactive protein, albumin, prealbumin and pre-vaccination HIA protective titre.

Results: The rate of HIA production was lower in HD patients than in controls. Factor increases in geometric mean titer for the H1N1 strain were 2.9 in HD and 6.6 in controls ($p<0.001$), with the respective figures being 2.8 and 3.1 (p=ns) for the H3N2 strain, and 2.4 and 4.7 ($P<0.05$) for the B strain. Also, post-vaccination seroconversion rates were lower in the HD group than in controls (43% versus 73% against the H1N1 strain; $p<0.05$; 43% versus 53% against the H3N2 strain; p=ns; and 36% versus 62% against the strain B; $p<0.05$). According to the regression model (adjusted R^2 0.298, $p<0.00001$), the predictors of low HIA production against H1N1 strain were high age ($p<0.0001$), dependence on dialysis (p=0.011) and high transferrin saturation (p=0,03).

Conclusions: The immune response to the influenza vaccine was lower in HD patients than in controls. Besides dependence on dialysis, the most significant predictors of low antibody production were high age of vaccinated subjects and high transferrin saturation. Immune response was independent of other markers of iron metabolism and inflammation.

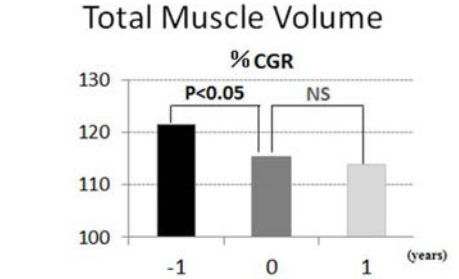
Intravenous Administration of L-Carnitine (LC) May Maintain the Muscle Volume in Hemodialysis (HD) Patients

Jyunichiro Hashiguchi,[1] Takuhisa Uchino,[1] Miki Yano,[1] Satoshi Funakoshi,[1] Osamu Sasaki,[1] Hiroshi Ichinose,[1] Kenji Sawase,[1] Yoko Obata,[2] Tomoya Nishino,[2] Yutaka Mori,[3] Kazunori Utsunomiya,[3] Takashi Harada.[1] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Univ Graduate School of Medicine, Nagasaki, Japan; [3]Jikei Univ, Tokyo, Japan.*

Background: Patients on maintenance HD usually suffer from dialysis-related carnitine deficiency, causing various clinical symptoms. At Carnitine Consensus Conference in 2003 convened by The National Kidney Foundation, the level of evidence was strongest for the treatment of anemia, and weakest for the response of muscle weakness. We hereby investigated whether intravenous administration of LC can maintain the muscle volume in HD patients as assessed by % creatinine generation rate (CGR).

Methods: Thirty-eight HD patients were enrolled in this study after appropriate informed consent. Subjects were treated with intravenous administration of 1000mg / body of LC at the end of every HD session for 12 months, then assessed by %CGR. Normalized protein catabolic rate (nPCR), geriatric nutritional risk index (GNRI) as well as serum albumin or hemoglobin levels were measured at the tree points; 1 year prior to the treatment, the start of LC administration and1 year after the treatment.

Results: As shown in Figure 1, average %CGR significantly declined during 1 year before the start of LC, and then stabilized 1 year after the treatment, suggesting LC administration might prevent the loss of muscle volume. Serum albumin, hemoglobin, nPCR and GNRI stayed the same level during observation period.



Albumin	(g/dL)	3.5+1.1	3.4+0.9	3.6+1.1	NS
Hb	(g/dL)	10.8±1.7	11.0±0.7	11.1+1.1	NS
GNRI		93.3±10.4	92.9±9.8	94.0±11.1	NS
nPCR	(g/day)	1.2±0.2	1.3±0.4	1.4±0.2	NS

Conclusions: Intravenous LC administration may potentially maintain the muscle volume in patients undergoing HD.

Nutrition Analysis Mobile Application in Patients with Chronic Kidney Disease Chayakrit Krittanawong,[1] Sakkarin Chirapongsathorn,[2,3] Zhen Wang,[4] Hua Ann Jenny Lu.[5] *[1]Div of Cardiovascular Disease, Mayo Clinic, Rochester, MN; [2]Div of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN; [3]Div of Gastroenterology, Dept of Medicine, Phramongkutklao Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand; [4]Dept of Healthcare Policy and Research, Mayo Clinic, Rochester, MN; [5]Div of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.*

Background: While mobile phone applications have become increasingly important in the last decade, few eating healthy mobile applications exist for patients. Yet in their daily lives, patients on a restricted diet often lack instant access to health information with regards to the food that is in front of them. It is therefore an objective of this pilot project to introduce a device that patients can utilize to overcome such problems.

Methods: The nutrition analysis application is named "GoFoody Project" and primarily consists of two functions: a scanning system and a recommendation system.

Results: The first major component of this invention is the food scanning and recognition process, which is comprised of two sub-processes: a photo recognition and a barcode scanning. In the photo recognition, the user can take a picture of food and send it to the cloud database for further processing, regardless of their location. Second, the recommendation system compares the patient's medical profile with their consumptions records in order to make health and dietary suggestions.

Conclusions: Over the next few years, we anticipated that this invention will be popular in grocery stores such as Walmart, Target, etc. We plan to demonstrate our invention to the healthcare industry by using the example of computer vision technology and cloud database.

FR-PO884

Lipoxin A_4 Attenuates Obesity-Induced Adipose Inflammation and Associated Liver and Kidney Disease Emma Borgeson,[1,2] Kumar Sharma,[1] Catherine Godson.[2] *[1]Center for Renal Translational Medicine, Inst for Metabolomic Medicine, UC San Diego, San Diego, CA; [2]Diabetes Complications Research Centre, Conway Inst, Univ College Dublin, Dublin, Ireland.*

Background: Visceral obesity and adipose inflammation is considered a driving force of systemic disease, e.g. chronic kidney disease (CKD). Inflammatory resolution is actively regulated by specialized pro-resolving mediators (SPMs), including the lipid LXA4. Impairment of SPMs may underlie development of obesity-related pathology. Here we explored the therapeutic potential of LXA4 in experimental obesity-induced systemic disease, e.g. liver cirrhosis and CKD.

Methods: C57BL/6 or Adiponectin-/- mice were fed a standard (10% fat) or high fat (60% fat) diet for 12 wks. LXA4 (5ng/g) and benzo-LXA4 analogue (1.7 ng/g) were given as interventional therapeutics i.p. 3 times weekly, between wk 5-12. Furthermore, omental adipose tissue biopsies were isolated from obese (BMI 35-50) bariatric surgery patients (n=4). Adipose explants were incubated with vehicle or LXA4 (1 nM) for 6h at 37 °C, and leukocytes were characterized by flow cytometry.

Results: Obesity caused distinct pathologies, including impaired glucose-tolerance, adipose inflammation, fatty liver and CKD. Lipoxins attenuated obesity-induced CKD; reducing glomerular expansion, mesangial matrix and urinary H_2O_2. Furthermore, LXA_4 reduced liver weight, serum alanine-aminotransferase and hepatic triglycerides. LXA_4 decreased obesity-induced adipose inflammation, attenuating TNF-α and $CD11c^+$ M1-macrophages (MFs), while restoring $CD206^+$ M2-MFs and increasing Annexin-A1. Lipoxins did not affect renal or hepatic MFs, suggesting protection occurred *via* attenuation of adipose inflammation. Lipoxins restored adipose expression of autophagy markers LC3-II and p62. LX-mediated protection was demonstrable in $adiponectin^{-/-}$ mice, suggesting that the mechanism was adiponectin independent. The ongoing clinical studies are characterizing whether Lipoxins promote an M1-to-M2 MFs phenotype shift in human omental adipose tissue.

Conclusions: In conclusion, Lipoxins protect against obesity-induced systemic disease and these data support a novel therapeutic paradigm for treating obesity and associated CKD.

FR-PO885

Prevalence of Protein-Energy Wasting Syndrome and Its Association with Anemia, Erythropoietin Resistance, Overhydration and Body Composition in Hemodialysis Patients Carlos Adrián Chávez- Mendoza, Jose Luis Ortega vargas, Jorge Osvaldo Montes rivera, Ricardo Correa-Rotter, Olynka Vega-Vega. *Nephrology and Mineral Metabolism, National Inst of Medical Science and Nutrition Salvador Zubiran, Mexico City, Mexico.*

Background: The prevalence of protein-energy wasting syndrome (PEW) in Mexican hemodialysis (HD) patients is unknown. Accordingly, there is no information on which clinical, biochemical, quality of life (QL), and body composition (BC) variables are associated or predictive of PEW in this population.

Methods: Observational comparative study that included 191 prevalent HD patients. BC was determined by BIS employing (BCM,Fresenius®), QL was measured with KDQOL-36 and presence of PEW according to ISRNM criteria.

Results: General characteristics are shown in Figure 1, prevalence of PEW was 22%(n=41). No differences between groups (with or without PEW) were present in:age, Charlson index, number and type of drugs employed, time on dialysis, vascular access, history of PD or kidney transplant and hospitalization days in the last year. PEW patients had a higher prevalence of DM(p=0.04), lower Hb(p=0.006) and higher EPO requirements(p=0.04) despite similar iron reserves. In terms of BC, PEW patients had more overhydration (OH) and higher extracellular water (ECW), and lower lean and fat tissue indexes (LTI,FTI). Surprisingly, QL indicators were not different between groups. In a Cox multivariate logistic regression model analysis, predictors of PEW were:degree OH(OR 3.2,95% CI 1.2-8.3,p<0.001), and ECW(OR 0.51,95% CI 0.22-0.89,p<0.01).

Figure 1. Differences between PEW and No PEW patients in chronic HD

	RRT – HD n= 191	PEW n= 41	No PEW n= 150	*p*

Total body water [TBW], ml/kg	514.92 ± 85.2	540.04 ± 99.5	514.09 ± 85.3	0.17
Overhydratation [OH], ml/kg	30.4 ± 24.2	43.05 ± 26.5	27.39 ± 22.8	<0.001
Extracellular water [ECW], ml/kg	246.46 ± 31.9	263.13 ± 39.6	246.17 ± 31.9	0.01
Intracellular water [ECW], ml/kg	268.43 ± 59.2	277.12 ± 66	267.89 ± 59.2	0.47
Lean tissue index [LTI], kg/m^2	13.70 ± 3.6	12.21 ± 3.2	14.03 ± 3.7	0.02
Fat tissue index [FTI], kg/m^2	11.82 ± 6.2	9.61 ± 5.7	12.33 ± 6.2	0.04
Body cell mas [BCM], kg	19.9 ± 7.8	16.3 ± 5.7	20.7 ± 8	0.009
Hemoglobin, mg/dL	10.1 ± 1.7	9.5 ± 1.6	10.3 ± 1.6	0.005
EPO, UI/ kg/wk	156.49 ± 73.8	171.2 ± 100.6	142.6 ± 59.8	0.04
Ferritin, ng/ml	360 ± 547.8	463 ± 660.8	331.4 ± 511.1	0.17
Transferrin saturation, %	27.3 ± 20.3	31.7 ± 29.1	26.1 ± 17	0.12
Physical Composite	35.5 ± 10	35.4 ± 11	35.5 ± 10	0.95
Mental Composite	50.0 ± 12	49.6 ± 11	50.0 ± 12	0.85
Handgrip strength, kg	26.5 ± 9.3	22.5 ± 7.1	28.1 ± 9.6	0.002

Conclusions: Prevalence of PEW in the studied population was lower compared to other series. PEW patients exhibit a state of overhydration which is given by increased ECW, and accompanied by loss of LTI and FTI. No PEW impact on QL was observed. PEW patients have increased anemia and higher requirements of EPO possibly associated to chronic inflammation.

FR-PO886

Efficacy of Nutrition Counseling on Protein Intake Restriction in Chronic Kidney Disease Patients – Niigata Part of SOFT-J (Study on Regional Variation of FROM-J Intervention by JSN) Ryohei Kaseda,[1] Michihiro Hosojima,[1] Toshiko Murayama,[1] Akihiko Saito,[1] Yoshiki Suzuki,[1] Kunihiro Yamagata,[2] Ichiei Narita.[1] *[1]Niigata Univ, Japan; [2]Tsukuba Univ, Japan.*

Background: Low adherence is frequently observed in patients with chronic kidney disease (CKD) who are following a diet therapy. This study evaluated the efficacy of nutrition counseling focused on protein restriction for CKD patients in clinics by national registered dietician using iPad and textbook used in FROM-J (Frontier of Renal Outcome Modification in Japan) study, aiming at promoting relationship between home doctor and nephrologist.

Methods: 47 patients with CKD stage3 (eGFR 30-59 ml/min/1.73m^2), age 40-85 were recruited. Nutrition counseling was conducted once for 30 min by national registered dieticians using iPad and textbooks in clinics without any dieticians in the staff. Optimal protein and energy intake were prescribed as 0.9 g/kg/day and 25-30 kcal/kg/day, respectively. The amount of protein intake was estimated from dietary records and by 24 hours urine collection before and 2 months after counseling (pre/post, respectively).

Results: All patients recorded their daily diets, 26/47 provided 24 hours urine collections. Counseling significantly decreased protein intake (record pre 1.10±0.23 g/kg/day post 1.00±0.26 p=0.001, urine pre 1.02±0.29 post 0.91±0.22 p=0.04). Although energy intake slightly decreased (record pre 31.9±6.4 kcal/kg/day post 30.1±5.2 p=0.03), this was not below the prescribed optimal calories. Salt intake decreased in recorded data but not in urine data (record pre 8.4±2.8 g/day post 7.6±2.7 p=0.03, urine pre 9.0±4.2 post 9.1±4.4 p=0.86, respectively). There was no significant difference in body mass index, eGFR, HbA1c (diabetic patients), LDL cholesterol, uric acid and blood pressure.

Conclusions: iPad and textbook counseling by dieticians is effective in reducing protein intake without compromising necessary caloric requirements, even in clinics without regular nephrologist or dietary staff. Informational technology may be an effective method of delivering on-demand nutritional counseling that can directly benefit patient care.

FR-PO887

Activin B Has a Functional Role in Hepcidin Induction by Inflammation Jodie L. Babitt, Susanna Canali, Amanda B. Core, Maria Merkulova, Kimberly Zumbrennen-Bullough. *Nephrology Div, Program in Membrane Biology, Center for Systems Biology, Massachusetts General Hospital, Harvard Medical School, Boston, MA.*

Background: Induction of the iron regulatory hormone hepcidin contributes to the anemia of chronic kidney disease by restricting iron availability. Bone morphogenetic protein 6 (BMP6) signaling is a central transcriptional regulator of hepcidin. Recently, the transforming growth factor-β (TGF-β)/BMP superfamily member Activin B was implicated in hepcidin induction by inflammation via noncanonical SMAD1/5/8 signaling, but its mechanism of action and functional significance *in vivo* remain uncertain.

Methods: Hep3B cells and primary hepatocytes were treated with Activin B, BMP6, or Activin A, without or with siRNA knockdown of Activin/BMP pathway components, and were tested for SMAD2/3 versus SMAD1/5/8 phosphorylation and hepcidin expression. Liver Activin B expression was measured and the effect of the Activin inhibitor follistatin-315 was examined in multiple rodent models of anemia of inflammation.

Results: Activin B, but not Activin A, stimulated SMAD1/5/8 signaling and hepcidin expression in liver cells to a similar degree as canonical SMAD2/3 signaling, and with similar potency and kinetics compared with BMP6. Activin B induced hepcidin via classical Activin type II receptors ACVR2A and ACVR2B, noncanonical BMP type I receptors ALK2 and ALK3, and SMAD5. The co-receptor hemojuvelin (HJV) bound directly to Activin B and facilitated Activin B-SMAD1/5/8 signaling. Activin B-SMAD1/5/8 signaling occurred selectively in hepatocyte-derived cells and was not enabled by HJV in other cell types. Liver Activin B mRNA expression was increased in multiple rodent models of inflammation associated with increased hepcidin and hypoferremia. Follistatin-315 had no effect on basal hepcidin expression, but blunted hepcidin induction by inflammation in mice.

Conclusions: Our data elucidate a novel mechanism for noncanonical SMAD activation by BMP/TGF-β superfamily members, and support a functional role for Activin B in hepcidin induction by inflammation *in vivo*. Targeting the Activin B-hepcidin pathway may lead to new therapies for anemia of inflammation including the anemia of chronic kidney disease.

FR-PO888

Effects of a Very Low Protein Diet Supplemented with Amino and Keto Acids on Skeletal Muscle Protein Synthesis and Degradation in Patients with Chronic Kidney Disease Giacomo Garibotto,[1,2] Antonella Sofia,[2] Valeria Cademartori,[2] Emanuele L. Parodi,[2] Francesca Ansaldo,[2] Daniela Verzola.[1] *[1]DIMI, Nephrology Div Genoa Univ, Genoa, Italy; [2]Dept Intern. Med., IRCCS AOU San Martino-IST, Genoa, Italy.*

Background: Chronic kidney disease (CKD) is characterized by progressive loss of muscle mass, an effect which could be accelerated by low (LPD) and very low protein diets (VLPD), even if essential amino/keto analogue (AA/KA) supplements are used. However, to what extent skeletal muscle protein metabolism adapts to a supplemented VLPD in CKD patients is still unexplored.

Methods: To determine the muscle responses to a supplemented VLPD (0.45 g/kg+0.1 g/kg AA/KA, 35 kcal/Kg/day), as compared to a standard (0.55 g/kg,35 kcal/Kg/day) LPD, forearm [2H]phenylalanine kinetics were evaluated in six CKD patients(5M/2F, age 71±1 yrs, eGFR 11±1 ml/min) assigned to a LPD (4 weeks), followed by a 4- week supplemented VLPD period. Studies were performed after an overnight fast (post-absorptive state) and results express basal rates of protein turnover.

Results: After supplemented VLPD, as compared to a standard LPD: a) whole body protein turnover declined only slightly (0.51±2 vs. 0.55±2 μmol/min/kg, VLPD vs. LPD , p=NS) ; b) forearm protein net balance, i.e. the difference between protein synthesis and degradation, was less negative by 18% (from -11±3 to -9 ±2 nmol/min.100 ml, p<0.02) ; (c) the efficiency by which amino acids are cycled back from protein degradation into protein synthesis increased by 15% (p<0.05); d)muscle protein degradation was unchanged (from 44±4 to 46±5 nmol/min.100 ml , p<0.02); e) Protein synthesis increased by 17% (from 33±1 to 38±4 nmol/min.100 ml, p<0.05).

Conclusions: Our data show that in patients with CKD stage 5 the response of muscle protein turnover to a AA/KA supplemented VLPD, as compared to a standard LPD, is characterized by similar reduced rates of protein degradation, but an increase in muscle protein synthesis, with enhanced recycling of amino acid derived from catabolism. Net protein balance is less negative, which suggests that the use of AA/KA supplemented VLPD may be nutritionally safer than a standard LPD.

FR-PO889

Risk of Anemia and Blood Transfusion following Reduction of Maximum ESA Doses Kelvin C.W. Leung, Robert R. Quinn, Braden J. Manns, Jennifer M. MacRae, Pietro Ravani. *Medicine, Univ of Calgary, Calgary, AB, Canada.*

Background: The cost of providing erythropoietin stimulating agents (ESAs) for renal patients is currently covered in the province of Alberta, Canada. Due to the high costs associated with therapy, the provincial funding agency reduced the maximum weekly ESA dose by 50%. We sought to determine the clinical impact of this policy change on the risk of severe anemia (hemoglobin [HGB] <90g/L) and transfusions.

Methods: All patients in the Southern Alberta Renal Program with a HGB >90g/L and receiving more than darbepoetin 75ug/wk or epoetin 15000 units/wk were reduced to an equivalent of darbepoetin 75ug/wk in September 2013. Serum HGB, iron stores, serum albumin, and parathyroid hormone assessed at baseline, 3 months, and at 6 months (end of study). Blood transfusion data was extracted from provincial electronic records. Patients were returned to a higher ESA dose when the HGB declined to ≤90g/L. We performed Kaplan-Meier analysis and multivariable regression analysis to calculate the median time to a drop in HGB level to ≤90g/L (primary outcome) and the receipt of blood transfusions (secondary outcome) following ESA dose reduction. ESA doses were re-established in people who reached the primary end-point.

Results: patients (mean age 61±16 years) met the inclusion criteria. The majority of patients were treated with hemodialysis (75%) and received darbepoetin (81%). The mean baseline darbepoetin dose (or equivalent for those treated with epoetin) was 110±28ug/week; mean baseline HGB was 106±12g/L. A HGB of ≤90g/L was reached in 50% of the cohort by 4.1 months (median 1.8 months, IQR 0.4-2.8 months). Blood transfusions occurred in 15% of the cohort during the study and 12% in preceding 3 months (p=0.77). In multivariate analysis, only higher baseline HGB levels were associated with reduced hazard of a drop in HGB to ≤90g/L. Baseline ESA dose, magnitude of ESA dose reduction, and baseline iron stores was not independently associated with our primary outcome.

Conclusions: HGB declines below 90 g/L in about four months following ESA dose reduction. The short-term risk of blood transfusion remains similar. The clinical and economic implications of this policy remain to be determined.

FR-PO890

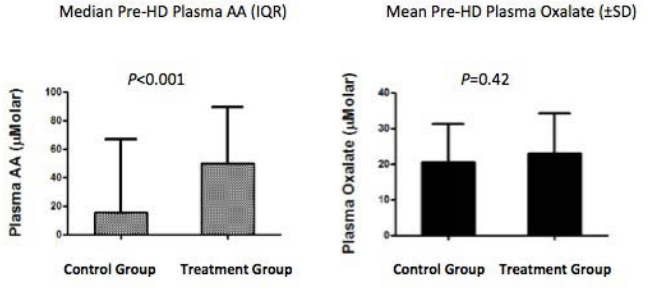
Association of Moderate Ascorbic Acid Supplementation with Plasma Ascorbic Acid and Oxalate Levels in Prevalent Hemodialysis Patients William D. Sirover,[1] Yuguan Liu,[2] Amanda Logan,[3] Krystal Hunter,[3] Craig B. Langman,[4] Lawrence S. Weisberg,[1] Garry J. Handelman.[2] *[1]Nephrology, Cooper Univ Healthcare, Camden, NJ; [2]Nutrition, Univ of MA Lowell, Lowell, MA; [3]Cooper Research Inst, Cooper Univ Healthcare, Camden, NJ; [4]Nephrology, Northwestern Univ, Chicago, IL.*

Background: Ascorbic acid (AA) supplementation may improve anemia in hemodialysis (HD) patients. Oxalate (Ox), an AA-metabolite, is excreted in the urine and is also removed during HD. When the plasma Ox concentration (plasma [Ox]) reaches 30 μM, Ox may deposit pathologically in organs. Moderate oral AA supplementation--up to 100 mg of AA/day--is often prescribed to HD patients. Of concern, patients who received earlier forms of HD could develop pre-HD Ox levels of 30 μM or higher when taking this degree of AA. We hypothesize that moderate AA use is not associated with an increase in pre-HD plasma [Ox] when patients receive high-flux HD.

Methods: In 2011, we surveyed outpatients on HD regarding AA supplement use. Pre-HD AA and Ox levels were measured. The treatment group consisted of patients who took up to 100 mg of oral AA/day. Patients who took no AA comprised the control group.

Results: There was no difference in pre-HD plasma [Ox] (mean±SD) between the treatment and the control groups, 21.9±10.1 μM vs. 20.6±10.6 μM, respectively (P=0.42). Median plasma AA concentration was 47.2 μM (IQR 24.6-83.6) in the treatment group and 15.8 μM (IQR 8.5-67) in the control group, (P<0.001).

	Treatment Group(N=132)	Control Group(N=54)	*P*-value
AA supplementation (number) 50-75 mg/day 100 mg/day	 19 113	 -- --	
Age(yrs)	61±15	61±17	0.98
spKt/V	1.76±0.27	1.73±0.31	0.50
Albumin(gm/dL)	3.9±0.3	3.9±0.4	0.38
BMI(kg/M^2)	28.6±7.8	28.4±8.1	0.90



Conclusions: These findings support the notion that moderate AA supplementation may be able to safely and effectively raise plasma AA levels.

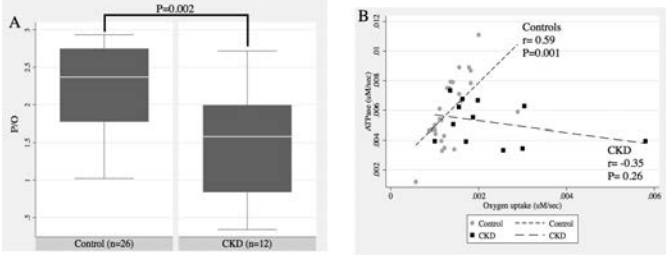
Chronic Kidney Disease Is Associated with Altered Muscle Mitochondrial Energetics by Functional MR Spectroscopy and Optical Spectroscopy

Baback Roshanravan,[1] Bryan R. Kestenbaum,[1] Jorge Gamboa,[2] Jonathan Himmelfarb,[1] Ian H. De Boer,[1] Kevin Conley.[1] *[1]Medicine, Kidney Research Inst - Univ Washington, Seattle, WA; [2]Vanderbilt Univ, Nashville, TN.*

Background: Exercise intolerance and muscle weakness are frequent clinical complications of CKD associated with adverse health outcomes, yet the pathophysiology underlying these conditions is poorly understood.

Methods: Cross-sectional study of *in vivo* muscle mitochondrial energetics using ^{31}P Magnetic Resonance Spectroscopy and optical spectroscopy (MRS/OS) in 12 subjects with non-diabetic CKD (eGFR<60) and 26 controls. ^{31}P MRS and OS were performed on the hand muscle under controlled ischemia. ATPflux (ATPase rate) was measured from phosphocreatine breakdown. Hemoglobin and myoglobin desaturation rates were assessed by OS to measure muscle oxygen uptake (O_2 uptake). The primary outcome was the coupling efficiency of mitochondrial oxidative phosphorylation ATP production (ATPflux) per unit of oxygen consumed (O_2 uptake) or P/O ratio. Grip strength and timed up and go were assessed. Pearson's correlation coefficient was calculated for univariable associations. We used multivariable linear regression adjusting for age.

Results: Mean age of CKD patients was 53±13yrs. Physical performance of the CKD group was no different from predicted normal values. Mean P/O values were 1.46±0.7 in the CKD group *vs.* 2.22±0.6 in the control group (age-adjusted P=0.002). The strongest correlates of P/O ratio age (ρ=-0.42), followed by eGFR (ρ=0.32). In contrast to controls, patients with CKD had higher O_2 uptake (P=0.03) without concomitant change in ATPase rate.



Conclusions: Application of non-invasive tools reveals that CKD is associated with greater muscle O_2 uptake reflecting uncoupling of oxidative phosphorylation. These results suggest altered mitochondrial respiration in skeletal muscle of patients with CKD prior to dialysis.

Improving Outcomes with Nutrition in Older People with Advanced Chronic Kidney Disease – Baseline Data from a Pilot Randomised Controlled Trial

Lina Johansson,[1] Mary Hickson,[1] Edwina A. Brown.[2] *[1]Nutrition and Dietetics, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial Kidney and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.*

Background: It is difficult to determine when to start dialysis in older people as creatinine and eGFR can be misleading. Dialysis start is often determined by weight loss, symptoms, potassium and fluid overload, all of which are potentially modifiable with nutrition. This pilot RCT aims to determine whether dietary interventions can result in improved patient outcomes, including time to dialysis, in older people with advanced chronic kidney disease (CKD).

Methods: Patients ≥65 years, with eGFR 10-20mls/min were randomised to an observational or intervention group (greater dietetic input). Data will be collected every 6 months for up to 2 years: nutritional status (Subjective Global Assessment), symptoms (Palliative Outcome Scale – Symptoms Renal), function (4 metre walk gait speed test and Jamar handgrip dynamometer) and fluid overload using Body Composition Monitor (Fresenius).

Results: 80 patients were recruited, baseline data presented. The 2 groups have statistically similar baseline demographic and clinical characteristics. Overall, 30% have malnutrition of which 58% are overweight/obese. 28% have nutritionally relevant potentially uraemic symptoms (nausea, vomiting and/or poor appetite). Fluid overload (>2L) was observed in 22% of those that were assessed (n=58).

Demographics	**Control (n =40)**	**Intervention (n=40)**
Male n (%)	27 (67.5)	26 (65.0)
Age years, mean (SD)	74.5 (6.8)	76.0 (7.4)
Diabetes n (%)	19 (47.5)	18 (45.0)
Biochemistry		
eGFR mls/min, mean (SD)	16 (4)	16 (3)
Potassium >5.5mmol/L %	10	5
Nutritional status and symptoms		
Subjective Global Assessment (SGA) malnourished %	38	23
Nausea, vomiting and/or poor appetite %	25	30
Physical function		
Gait speed <0.8m/sec, indicative of gait impairment %	45	48
Handgrip strength ≤20kg women or ≤ 30kg men, indicative of weakness %	50	58

Conclusions: There is a high prevalence of indications for dietetic interventions within older people with advanced CKD at baseline which may positively affect outcomes within two years.

FR-PO893

Retention of Acetylcarnitine in Chronic Kidney Disease Causes Insulin Resistance in Skeletal Muscle

Yasunori Miyamoto,[1] Teruo Miyazaki,[2] Akira Honda,[2] Homare Shimohata,[1] Kouichi Hirayama,[1] Masaki Kobayashi.[1] *[1]Nephrology, Tokyo Medical Univ Ibaraki Medical Center, Ami, Ibaraki, Japan; [2]Joint Research Center, Tokyo Medical Univ Ibaraki Medical Center, Ami, Ibaraki, Japan.*

Background: Insulin resistance occurs frequently in patients with chronic kidney disease (CKD) and ameliorates after introduction of hemodialysis (HD). However, the mechanisms of insulin resistance associated with CKD are unclear. An increased mitochondrial acetyl-CoA/CoA ratio causes insulin resistance in skeletal muscle, and this ratio is regulated by carnitine acetyltransferase (CAT), which transfers excess acetyl moieties to carnitine (CT). Because the resulting acetylcarnitine (AcCT) is excreted in urine, we hypothesized that retention of AcCT might be a cause of insulin resistance in patients with CKD.

Methods: Serum samples were collected from 64 patients with CKD (including 14 HD patients) and 31 control subjects who underwent a medical examination. CT and AcCT concentrations in sera were measured by HPLC-ESI-MS/MS. The effects of exogenous AcCT (0-300 µM) on insulin-dependent 2-deoxyglucose (2DG) uptake, mitochondrial CT and AcCT levels, and the mitochondrial acetyl-CoA/CoA ratio were examined in a cultured skeletal muscle cell line (C2C12 myotubes).

Results: The serum concentration of AcCT, but not that of CT, significantly increased with reduction of renal function, as classified by eGFR (stage £2 3.7 ± 0.6 µM, stage 3a 6.1 ± 1.1 µM, stage 3b 10.9 ± 1.9 µM, stage 4 16.3 ± 2.1 µM, stage 5 28.2 ± 5.9 µM, mean ± SEM). After introduction of HD, the increased AcCT levels were significantly reduced (pre 16.8±2.5 µM, post 6.3 ± 0.7 µM). In vitro experiments in skeletal muscle cell lines showed that uptake of 2DG was significantly and dose-dependently inhibited by addition

of AcCT. The added AcCT was converted to CT through the reverse reaction of CAT, and thus the acetyl-CoA concentration and acetyl-CoA/CoA ratio in mitochondria were significantly elevated.

Conclusions: The results suggest that increased AcCT in patients with CKD causes insulin resistance in skeletal muscle by stimulating the reverse reaction of CAT, which leads to accumulation of acetyl-CoA in mitochondria.

High Protein Intake in Relation to Incident End-Stage Renal Disease (ESRD) Among Blacks and Whites in the Southern Community Cohort Study (SCCS)

Rakesh Malhotra, Edmond Kato Kabagambe, Kerri L. Cavanaugh, William J. Blot, Talat Alp Ikizler, Loren Lipworth. *Vanderbilt Univ Medical Center.*

Background: Dietary composition could contribute in part to observed racial disparities in ESRD incidence. Diabetes, a major risk factor for ESRD, may lead to differences in dietary intake and metabolism. We examined whether protein intake is associated with ESRD risk and whether the association varies by race and diabetes.

Methods: We conducted a nested case-control study of ESRD within the SCCS, a prospective study of low income blacks and whites in the southeastern US (2002-2009). Through 2012, 1,074 incident ESRD cases were ascertained by linkage with the USRDS, and matched to 3,230 controls on age, sex and race. A validated food frequency questionnaire was administered at baseline. Odds ratios (OR) and 95% confidence intervals (CI) for ESRD were computed in relation to protein intake, expressed as daily % of total energy intake and modeled in 1 standard deviation (SD) increments in unconditional logistic regression models stratified by race and diabetes. ORs were adjusted for age, sex, BMI, education, income, hypertension, total energy intake and % energy from saturated and polyunsaturated fat.

Results: Median daily % energy intakes from protein were higher among whites than blacks and those with vs without diabetes, but differences between ESRD cases and controls were small (15.9 and 15.7%, respectively, for blacks with diabetes, 14.6 and 14.6% for blacks without diabetes, 16.6 and 16.4% for whites with diabetes, and 15.1 and 15.1% for whites without diabetes). For a 1 SD (3.17%) increase in daily % energy intake from protein, adjusted ORs (95% CI) for ESRD were 1.18 (1.05-1.34) for blacks with diabetes, 1.06 (0.93-1.21) for blacks without diabetes, 0.89 (0.61-1.30) for whites with diabetes and 1.00 (0.74-1.33) for whites without diabetes.

Conclusions: Our results raise the possibility that among blacks with diabetes, a diet higher in protein is associated with increased incidence of ESRD. If confirmed, future studies might examine contributors leading to adverse outcomes associated with high protein intake in this subpopulation.

Effects of Lanthanum Carbonate on Intestinal Bacterial Flora in Chronic Renal Failure Mice

Minoru Satoh, Hiroyuki Kadoya, Seiji Itano, Atsushi Uchida, Yuji Sogawa, Hajime Nagasu, Tamaki Sasaki, Naoki Kashihara. *Dept of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.*

Background: The intestinal microbial flora consists of diverse bacterial species that inhabit the gastrointestinal tract. These bacteria are integral to the ontogeny and regulation of the immune system, and maintenance of intestinal homeostasis. In the chronic kidney diseases, changes of the intestinal bacterial flora have been reported, which contribute to nutritional disorder, systemic or local inflammation, and the uremic toxin production. Phosphate promotes a bacterial growth. So, by phosphate adsorption, intestinal bacterial flora may be changed. We examined whether phosphorus adsorption with lanthanum carbonate could change intestinal bacterial flora in renal failure mice.

Methods: We used 5 weeks old male ICR-derived glomerulonephritis (ICGN) mice (n=10) for renal failure group and ICR mice (n=10) for control group. Each group mice were fed with standard diet or diet supplemented with 3% lanthanum carbonate for 10 weeks. Gene expression patterns of a whole bacterial flora in the intestine were analyzed by terminal restriction fragment length polymorphism analysis method. Fecal bacteria products (phenol, para-cresol, indole and skatole) were examined by quantitative chemical analysis.

Results: The ratio of "bad" bacteria clostridia was increased, and the ratio of opportunistic pathogen bacteroides was decreased in intestinal bacterial flora of ICGN mice. By the lanthanum carbonate administration, the ratio of clostridium was decreased, and the ratio of beneficial bacterium lactobacilli was increased. Fecal bacteria products phenol and para-cresol were increased in feces of ICGN mouse, but indole was not changed. Skatole was not detected in feces of both mice. Among intestinal bacterial flora, the ratio of clostridium showed a positive correlation, and the ratio of bacteroides showed a negative correlation of phenol production.

Conclusions: The intestinal bacterial flora in chronic renal failure mice was changed by lanthanum carbonate administration.The change of the bacterial flora affected the fecal bacteria products, which may contribute the production of serum uremic toxin.

FR-PO896

High-Fat Diet Induces the Production of IKKε by Macrophages to Promote Nephrotoxicity

Xin Wan,[1] Binbin Pan,[1] Changchun Cao.[1] *[1]Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital).*

Background: The NF-κB activation may participate in lipid nephrotoxicity which may be regulated by inhibitor kappa B kinase epsilon (IKKε). To investigate the role of IKKε in this procession, mice experiment was performed.

Methods: Mice were grouped: (1) wild-type with normal fat diet (WN), (2) wild-type with high fat diet (WH), (3) IKKε knockout with normal fat diet (KN), (4) IKKε knockout with high fat diet (KH). Renal function, lipid, histological changes and tubular proliferation were analysed. IL-1β, TNF-β, p50 and p65 were determined by western blot. NF-κB level was tested by EMSA. Expression of IKKε was evaluated via immunohistochemistry and immunofluorescence.

Results: Cystatin C levels were significantly higher in WH group than others. Staining with hematoxylin-eosin revealed that tubular lesions in WH group (3.53 ± 0.21) were more severe than in WN group (0.32 ± 0.11). By Immunohistochemistry, WH group exhibited marked macrophages infiltration than WN, KN and KH groups. Western blot showed significant increase of IL-1β, TNF-β and marked increment in the expression of NF-κB pathway components consists of p50 and p65 in WH group, while these increases were blocked in KN and KH groups. Furthermore, NF-κB level in WH group was higher than other groups. WH group exhibited remarkable macrophages infiltration than other groups by Immunofluorescence. Immunohistochemistry showed remarkable increases in the expression of IKKε in the WH group compared with other groups. Immunofluorescence analysis demonstrated that the expression of IKKε was located around macrophages.

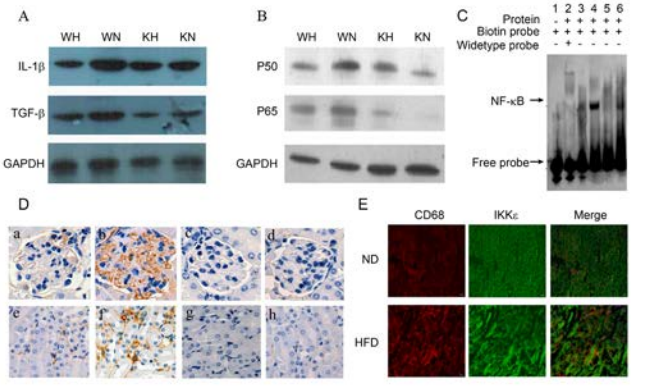

Figure 1A.
HFD induce inflammation and infiltration of macrophage.
Expression levels of IL-1β and TNF-β were significantly increased in the WH group compared to the WN group of mice after normalization to GAPDH, which can be attenuated in KN or KH group.

Figure 1B.
Protein expression of NF-κB cascade components determined by Western blotting.
Expression levels of P50 and P65 in kidney tissue, after normalization to GAPDH, were all significantly increased in the WH group compared to the WN group of mice, which can be decreased in KN and KH groups.

Figure 1C.
Activation of NF-κB determined by EMSA.
NF-κB activation in mice kidneys. Lane 1, labeled probe with no extract; lane 2, labeled probe with extract from WH group renal tissues plus 200-fold excess of unlabeled probe; lanes 3-6, NF-κB activities in each group: lane 3, WN group mice; lane 4, WH group mice; lane 5, KN group mice; and lane 6, KH group mice.

Figure 1D.
Expression of IKKε in tubulointerstitium and glomerulus of mice via immunohistochemical analysis after 24 weeks.
a, e: A small quantity of IKKε expressed in glomerulus and intersitium in WN group ;
b, f: Tubulointerstitium and mesangial region of mice revealed obvious expression of IKKε in WH group ;
c, g: No expression of IKKε was found in KN group;
d, h: No expression of IKKε was found in KH group.

Figure 1E.
Immunofluorescence of IKKε and macrophage in kidneys of WN and WH.
No obvious expression of IKKε in WN, some macrophages were observed. Obvious expression of IKKε was located around macrophage in interstitium and glomerulus in WH group.

Conclusions: IKKε mediates lipid nephrotoxicity by HFD induced macrophages infiltration to activate NF-κB signal pathway.

Clinical Determinants of Toll Like Receptor 4-Mediated Inflammatory Response in Skeletal Muscle of Patients with Chronic Kidney Disease

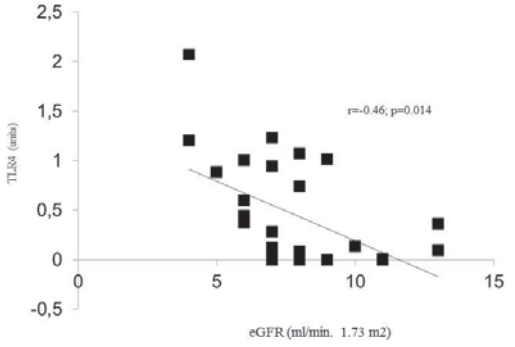
Daniela Verzola,[1] Alice Bonanni,[1] Antonella Sofia,[1] Francesca Ansaldo,[1] Elisa Veziano,[1] Valeria Cademartori,[1] Emanuele L. Parodi,[1] Giuliano Brunori,[2] Chiara Venturelli,[2] Giacomo Garibotto.[1] *[1]DIMI, Nephrology Div., Univ of Genoa, Genoa, Italy; [2]Nephrology Div., Santa Chiara Hospital, Trento, Italy.*

Background: Inflammation in skeletal muscle is implicated in the pathogenesis of insulin resistance and cachexia. We previously observed that the Toll-like receptor-4 (TLR4) dependent muscle signaling is upregulated in muscle of CKD subjects.

Methods: We studied the associations between muscle (*rectus abdominis*) TLR4 protein (western blot and immunoistochemistry) and gene (rt-PCR) expression and clinical parameters in 38 CKD stage 5 patients (23M/15F, eGFR 8±1 ml/min).

Results: CKD subjects had significantly elevated TLR4 gene expression and protein content in muscle (~4-fold increase vs. controls $p<0.05$). LogTLR4 protein content in

muscle was inversely related to Subjective Global Assessment (SGA) (r=-0.410, p<0.03), eGFR (r=-0.46; p=0.014), hemoglobin (r=-0.380, p<0.05) and directly related to cholesterol levels (r=0.398, p<0.05).



There was no relationship between muscle logTLR4 and age, BMI, muscle area, nPNA, calorie intake, albumin, CRP, BUN, bicarbonate, triglycerides, fibrinogen, and phosphate levels. At multivariate analysis SGA and eGFR only contributed significantly to the prediction of TLR4 expression in muscle (p<0.003).

Conclusions: Both low SGA score (which indicates an overall concept of nutritional status) and eGFR (an index of residual renal function) play an independent role to predict TLR4 content in muscle of CKD patients.TLR4 content in muscle rises progressively along with progressive decline of residual renal function, with a 2-fold increase in TLR4 as eGFR declines from 12 to 5 ml/min. Both wasting and progressive loss of residual renal function are predictive of muscle inflammation.

Funding: Government Support - Non-U.S.

FR-PO898

Randomized, Double-Blind, Crossover Clinical Trial on Oral Rice Endosperm Protein Supplementation to Patients on Maintenance Hemodialysis

Michihiro Hosojima,[1] Hisaki Shimada,[2] Shigeru Miyazaki,[2] Yoshitsugu Obi,[3] Hazuki Kondo,[4] Mikio Fujii,[4] Reiko Watanabe,[5] Shoji Kuwahara,[6] Ryohei Kaseda,[1] Ichiei Narita,[7] Yoshiki Suzuki,[8] Motoni Kadowaki,[9] Akihiko Saito.[6] *[1]Dept of Clin Nutr Sci, Niigata Univ, Japan; [2]Shinraku-en Hospital, Japan; [3]Univ of California; [4]Kameda Seika Co., Ltd., Japan; [5]Univ of Niigata Prefecture, Japan; [6]Dept of Appl Mol Med, Niigata Univ, Japan; [7]Div of Clin Nephrol & Rheumatol, Niigata Univ, Japan; [8]Health Administr Center Div, Niigata Univ, Japan; [9]Faculty of Agriculture, Niigata Univ, Japan.*

Background: Protein-energy wasting, a state of metabolic and nutritional derangements, is an important risk factor that affects outcomes of patients with CKD, particularly in ones with ESRD and on maintenance dialysis (MHD).Purified rice endosperm protein (REP) contains less phosphorus (150 mg/100g) compared with soybean (787 mg/100g) and casein (737 mg/100g) proteins, and may improve nutritional status without imposing further metabolic derangements.

Methods: We carried out a randomized, double-blind, placebo-controlled, cross-over study to evaluate the effect of REP supplementation (5 g per day × 4 weeks) on nutritional and metabolic status in 50 MHD patients (UMIN000010876). The primary outcome was the change in urea kinetic-based normalized protein nitrogen appearance (nPNA), an indicator of protein intake in MHD patients. The inclusion criteria were: (1) nPNA < 1.2g/kg/day, (2) serum albumin concentration ≤ 3.8mg/dl, (3) body mass index ³19 kg/m² and <23 kg/m², (4) <5% variation in dry weight during the period of preceding 6 months, and (5) duration of MHD ≥ 2 years.

Results: By intention-to-treat analyses, REP increased nPNA by 0.07 (95%CI, 0.03-0.11) g/kg/day compared with placebo, whereas Dserum phosphorus concentration was not significantly different between the groups [0.18 (95%CI, -0.23-0.58) mg/dL]. REP did not show significant effects on other nutritional parameters. Per-protocol analyses yielded similar results. There were no specific complications associated with the REP supplementation.

Conclusions: Purified REP may be useful for dietary supplementation in MHD patients. Further studies are warranted to evaluate its long-term or high-dose efficacy.

Association of Serum Phosphate Levels and Mortality Risk in Patients with Chronic Kidney Disease: A Systematic Review and Meta-Analysis

Anawin Sanguankeo,[1,2] Sikarin Upala.[1,2] *[1]Internal Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY; [2]Preventive and Social Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.*

Background: Abnormalities of serum phosphate are associated with increased risk for mortality in end stage renal disease (ESRD) or dialysis patients. Use of phosphate binders has shown to reduce risk of mortality in these population and is recommended in several guidelines. However, there is still controversy on the management of serum phosphate in patients with chronic kidney disease (CKD). This meta-analysis evaluated the impact of serum phosphate on mortality in patients with CKD not requiring dialysis.

Methods: We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published RCT and prospective cohort studies assessing effects of high serum phosphate (compared to normal range) and a 1-mg/dL increase in phosphorus level in patients with CKD (eGFR <60 ml/min/1.73 m²). We excluded ESRD, dialysis, or renal transplant patients. The primary outcome was risk of all-cause mortality. We used hazard ratio (HR) or risk ratio (RR) in the multivariate model as an effect estimate.

Results: From 15 full-text articles, five studies involving 6,536 patients were included in the meta-analysis. All were prospective cohort studies of CKD stage 3 or 4 patients. There was an increase all-cause mortality risk in higher phosphorus levels (HR = 1.36, 95% CI: 1.24 to 1.0, p<0.01, I^2=0%) compared with normal phosphorus levels. A 1-mg/dL (0.1 mmol/L) elevation in serum phosphate also increases mortality risk with HR=1.23 (95% CI: 1.14-1.34, p<0.01, I^2=0%).

Conclusions: Elevated serum phosphate levels were independently associated with increased mortality risk among patients with CKD. Randomized controlled trials are needed to assess the benefits of using phosphate lowering therapy in patients with CKD before developing ESRD or dialysis.

FR-PO900

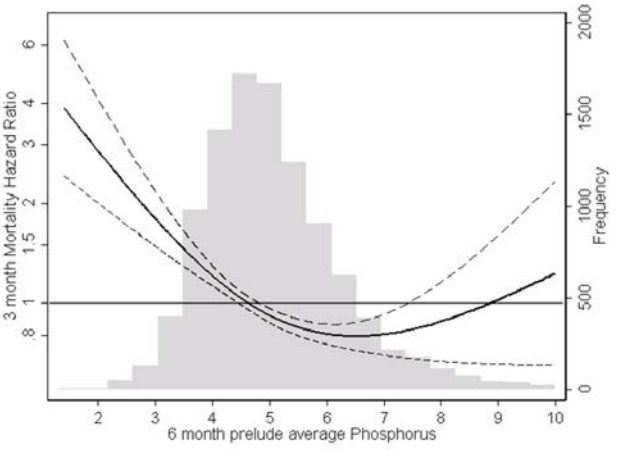
Serum Phosphorous Levels prior to Transition to Dialysis and Early Dialysis Mortality Among U.S. Veterans: A Transition of Care in CKD Study

Amanda R. Tortorici,[1] Yoshitsugu Obi,[1] Melissa Soohoo,[1] Connie Rhee,[1] Elani Streja,[1] Jennie Jing,[1] Rajiv Saran,[2] Bruce M. Robinson,[2] Yi Li,[2] Danh V. Nguyen,[1] Keith C. Norris,[3] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]UM-KECC; [3]UCLA; [4]UTHSC.*

Background: Previous studies have shown that higher phosphorous (Phos) levels were monotonically associated with higher risk of death in patients with chronic kidney disease and end-stage renal disease (ESRD). However, the impact of pre-ESRD Phos levels on early post-ESRD mortality is not known.

Methods: In US veterans who transitioned to dialysis between 10/2007 and 9/2011, we identified 10,724 patients with available Phos measurements within the last 6 month prelude period (prior to transition). We examined the association of Phos (averaged over 6 months) as a continuous predictor of all-cause mortality within the first 3 months post transition, using restricted cubic spline analysis and Cox models adjusted for age, sex, race, ethnicity, cause of ESRD, and region of residence.

Results: The mean±SD age of the cohort was 66±11 years, among whom 34% were African-American, 8% were Hispanic, and 52% had diabetes listed as their primary cause of ESRD. We observed a reverse J-shaped association between pre-ESRD Phos and 3-month post-ESRD mortality risk. Patients with Phos levels <4.7 mg/dL had a higher risk of mortality, and patients with Phos levels >9.0 mg/dL trended towards a higher risk of mortality as well. However, patients with Phos levels between 4.7 and 7.2 mg/dL demonstrated lower mortality risk.



Conclusions: Among veterans transitioning to dialysis, both lower and higher Phos levels were associated with higher risk of early post-ESRD mortality, while patients with Phos levels between 4.7 to 7.2 mg/dL had the lowest risk of mortality. Further studies are needed to determine if using dietary and medication interventions to attain this Phos range confers higher survival in this population.

FR-PO901

The Comparison of Serum Calcium, Phosphorus and Intact Parathyroid Hormone Between Peritoneal Dialysis Patients and Hemodialysis Patients

Guisen Li, Li Wang. *Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.*

Background: In this study, we compared the serum calcium, phosphorus and intact parathyroid hormone between peritoneal dialysis patients and hemodialysis patients to study the difference in MBD biochemical variables between PD and HD.

Methods: 507 patients were enrolled from July 1, 2014 to December 31, 2014, including 148 patients received peritoneal dialysis and 359 patients received hemodialysis patients (HD) more than 3 months. Basic clinical information, data of dialysis, serum calcium, phosphorus and iPTH levels were collected in all patients, and comparative analysis was carried out based on those information.

Results: The age and the dialysis vintage was significantly higher in HD group than in the PD group (P <0.001).Serum phosphorus was lower, percentage of phosphorus in target was higher and percentage of calcium in target was lower (P =0.271) in PD group than in HD group(P<0.001). The serum phosphorus levels of PD patients with peritoneal high transport characteristics or high average transport were much lower than those with low transport or low average transport(P = 0.0167). The levels of serum phosphorus (P <0.001), iPTH(P = 0.0167)and alkaline phosphatase(P<0.001)were much lower in patients with RRF³2ml/min than those with RRF<2ml/min. The levels of serum calcium (P <0.01), corrected calcium(P<0.01), phosphorus (P = 0.025), iPTH(P<0.001)and alkaline phosphatase(P <0.01)were much lower in patients with urine volume ³100ml/d than those <100ml/d. There was a negative correlation between RRF and serum phosphorus(r=-0.291, P <0.001)and iPTH(r=-0.271, <0.01)in PD group. The weekly total KT/V(r=-0.201,P = 0.019) and weekly total creatinine clearance(Ccr)(r=-0.407, P<0.001)negatively related to serum phosphorus. The Ccr(r=-0.241,P <0.01)negatively correlated with serum iPTH.

Conclusions: The serum levels of phosphorus is lower and the percentage of achieving target of serum phosphorus is higher in PD patients than HD patients.The peritoneal high transport characteristics, RRF³2ml/min, urine volume ³100ml/d and the nutrition status have obvious influence on the serum phosphorus and iPTH levels in PD patients.

FR-PO902

Increased Risk of Cerebral Hemorrhage in Hemodialysis Patients with Hyperphosphatemia: The Q-Cohort Study

Shunsuke Yamada,[1] Masanori Tokumoto,[3] Masatomo Taniguchi,[1] Takanari Kitazono,[1] Kazuhiko Tsuruya.[2] *[1]Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; [2]Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan; [3]Internal Medicine, Fukuoka Dental College, Fukuoka, Japan.*

Background: Mounting evidences have shown that hyperphosphatemia, an established component of CKD-MBD, accelerates cardiovascular disorders in dialysis patients. However, previous studies did not separately determine the effects of hyperphosphatemia on the onset of cerebrovascular disorders and cardiovascular disorders in dialysis patients.

Methods: The present study is an observational study consisting of 3431 outpatients undergoing hemodialysis. The associations between the baseline serum phosphate (Pi) level and the onset of cerebral bleeding and infarction were examined. Independent variable was serum Pi level. Dependent variable was the onset of cerebral hemorrhage and infarction. Age, sex, diabetes mellitus, history of cardiovascular events, dialysis vintage, Kt/V for urea, systolic blood pressure, hemoglobin, serum levels of calcium, parathyroid hormone, albumin, alkaline phosphatase, creatinine, and C-reactive protein, and use of vitamin D and Pi-binder were used as covariates. Cox proportional hazard model was used for analyses. All statistical analysis was conducted by JMP11.2 (SAS institute).

Results: The mean age of the examined population was 63.7±12.8 years, female was 41%, and the proportion of diabetes mellitus was 29%. Mean serum levels of calcium, Pi, and intact parathyroid hormone were 9.41±0.76 mg/dL, 4.92±1.2 mg/dL, 168±210 pg/mL, respectively. During the mean observational period of 3.1 years, 77 patients newly developed brain hemorrhage and 140 developed brain infarction. Hyperphosphatemia (Pi≥6 mg/dL) did not increase the risk of brain infarction, but increased the risk of brain hemorrhage by 2.2 fold, compared with the target Pi range (3.5£Pi<6.0 mg/dL), even after adjustment for the potential confounders.

Conclusions: Hyperphosphatemia is closely associated with the onset of cerebral hemorrhage but not with cerebral infarction. Our results highlight the importance of Pi management in the prevention of cerebral hemorrhage in dialysis patients.

Funding: Private Foundation Support

FR-PO903

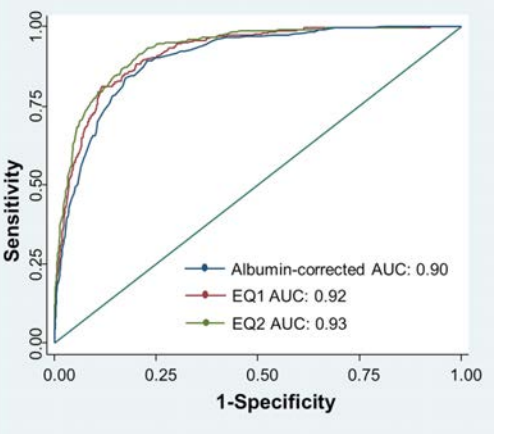
Development and Evaluation of Novel Correction Equations for Serum Calcium Concentrations in Hemodialysis Patients

Yoshitsugu Obi,[1] Wei Ling Lau,[1] Elani Streja,[1] Connie Rhee,[1] Steven M. Brunelli,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh.[1] *[1]UC Irvine; [2]DaVita Clinical Research; [3]UTHSC.*

Background: Ionized calcium (iCa),but not total calcium (tCa), is the physiologically relevant component of blood calcium. However, these measurements correlate poorly in hemodialysis patients even after correction for serum albumin, which may be partly explained by electrolyte and acid-base derangements in this population.

Methods: In 1,366 patients who initiated conventional HD over four years (1/2007-12/2010),we identified 6,830 iCa measurements where serum albumin, tCa, sodium, chloride, phosphorus, and bicarbonate were measured simultaneously. We randomly divided patients into a derivation set (n=681) or a validation set (n=685) to develop and evaluate new correction equations for serum tCa concentrations by comparing correlation r and Bayesian information criterion (BIC) in linear regression analysis as well as receiver operating characteristic (ROC) curves for hypercalcemia determined by iCa (≥5.28 mg/dL).

Results: Albumin was associated with iCa, but its coefficient was -0.15, not -0.8 as shown in the conventional correction equation. Furthermore, albumin-corrected tCa showed lower correlation than uncorrected tCa with iCa (r=0.69 and 0.76, respectively). Two equations were developed from the derivation set as follows; [EQ1] 1.1*tCa – 0.12*(phosphorus + 1) and [EQ2] 1.1*tCa – 0.08*(anion gap – 2). In the validation set, EQ1 and EQ2, compared to the conventional correction by albumin, showed better correlation with iCa (r=0.78 and 0.80, respectively), lower BIC (96% and 92%, respectively), and higher area under the ROC curve for iCa-defined hypercalcemia (P<0.01 for both).



Conclusions: Novel correction equations for tCa show better association with iCa and hypercalcemia evaluated by iCa. Its clinical usefulness needs to be evaluated in further studies.

Relationship Between Dietary Phosphorus Intake and Protein and Energy Intakes in Hemodialysis Patients

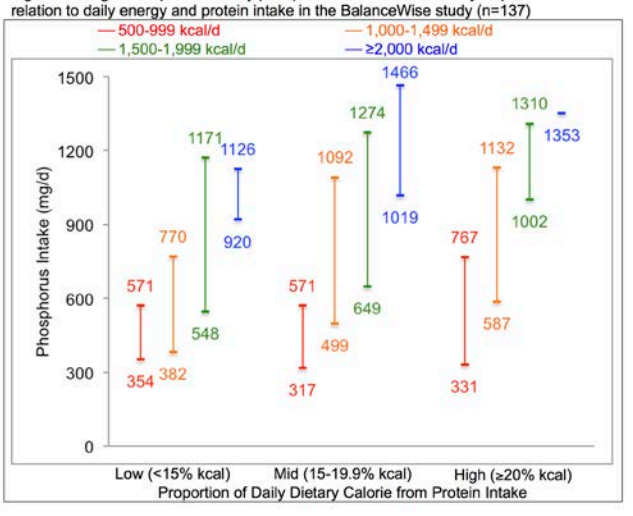
David E. St-Jules,[1] David S. Goldfarb,[2,3] Mary Lou Pompeii,[1] Kathleen Woolf,[4] Kamyar Kalantar-Zadeh,[5] Mary A. Sevick.[1] *[1]NYU School of Medicine; [2]NY Harbor VA Medical Center; [3]NYU Langone Medical Center; [4]NYU Steinhardt; [5]UCLA School of Public Health.*

Background: Excess dietary phosphorus may contribute to mineral and bone disorders in hemodialysis (HD) patients. However, many high phosphorus foods are also important sources of dietary protein, which raises concerns that phosphorus restriction may compromise protein status.

Methods: We conducted a cross-sectional study of 190 African American and white men and women on intermittent HD for >3 months. Dietary data were collected by three 24-hour recalls, which were analyzed using NDSR®. Only participants who completed all three recalls and reported intakes >500 kcal/d were included (n=137).

Results: Dietary phosphorus and protein were highly correlated (R^2=0.73). Based on linear regression, a 1,000 mg/d phosphorus restriction would provide about 78 g protein/d (or 1.1 g protein/kg/d for a 70-kg person). When adjusting for energy intake, the association of dietary phosphorus and protein was far less apparent (R^2=0.42). Further, the highest phosphorus intake was about two times greater than the lowest phosphorus intake for each energy and protein intake level (500 kcal and 5% of kcal increments), reaching 600 mg/d for some groups.

Figure1. Ranges in reported dietary phosphorus intake of hemodialysis patients in relation to daily energy and protein intake in the BalanceWise study (n=137)



Conclusions: Although dietary phosphorus and protein are highly correlated, this relationship appears to be driven in part by the amount of Calories consumed. Moreover, phosphorus intake ranges widely within energy and protein intake increments, suggesting that reductions in dietary phosphorus may be achieved in many HD patients without compromising the protein status.

Assessment of Barriers to Phosphorus Control in Dialysis Patients

Rashmi Bisla, Jasmin Sandhu, Vinod K. Bansal, Stephanie Kliethermes, Anuradha Wadhwa. *Loyola Univ Medical Center, Maywood, IL.*

Background: High phosphorus levels are associated with increased cardiovascular and all-cause mortality but Phosphorus control continues to be a challenge amongst dialysis patients. In this study, we conducted a survey to assess phosphorus control and identify barriers to phosphorous control in patients receiving dialysis at Loyola outpatient dialysis unit.

Methods: The study consisted of 17 question survey evaluating patients knowledge and understanding of phosphorus control, self care practices and social support as potential barriers to phosphorus control. Patients were approached during dialysis to participate. Objective patient data and laboratory data was collected from electronic medical records. Study was approved by Loyola IRB.

Results: Of the 99 eligible subjects, 57 completed the survey. Mean age of the participants was 62 years, 52% were males and 75% were African Americans. Patients were categorized into uncontrolled (phosphorus>=5.5 mg/dL) and controlled phosphorus group. The two groups had similar demographics, co-morbidities, dialysis adequacy and medication pill burden. Approximately 80% of patients with uncontrolled phosphorus were aware of normal phosphorus levels in dialysis patients, complications associated with high phosphorus and identified majority of foods with high phosphorus compared to 53%, 43% and 57% in the controlled phosphorus group, respectively. Patients with uncontrolled phosphorus frequently identified cheating on diet and missed medication dose as reasons for lack of phosphorus control. There was no difference among the two groups relative to social support or self-care practices. 75% patient in controlled and 55% in uncontrolled group were interested in learning more about phosphorus control.

Conclusions: Patients with uncontrolled phosphorus had significantly greater knowledge and understanding of phosphorus control. While continued education of patients regarding phosphorus control is important, qualitative research to study patients' behavioral aspects is needed to better understand barriers to phosphorus control.

FR-PO906

Use of a Simple, Widely Available Laboratory Test to Quantify and Explain Variation in Phosphorus Levels in Beverages

Elizabeth J. Lindley,[1] David Francis Keane,[1] Tracey Ying,[2] John W. MacD. Agar,[2] Gunnar H. Heine,[3] Juergen Geisel.[3] *[1]Leeds Teaching Hospitals NHS Trust, United Kingdom; [2]Geelong Hospital, Australia; [3]Saarland Univ Medical Centre, Germany.*

Background: Restriction of dietary phosphorus (P) is essential in the management of hyperphosphataemia in CKD. Beers and wines contain inorganic P that is readily absorbed but data on these beverages, and less well-known soft drinks, is difficult to obtain. An assay used routinely in hospital laboratories has been validated for measurement of P in a range of beverages (Lindley, J Ren Nutr 2014) enabling renal unit staff to compile information on locally sourced products and investigate variation between brands.

Methods: Beverages were processed as if they were urine samples and tested using the standard phosphomolybdate assay. 12 beers popular in the German Saarland were tested to find out if lower P brands could be identified. 10 wines from a micro-winery in New South Wales containing little or no di-ammonium phosphate (DAP, a widely-used yeast nutrient) were compared with 8 Australian wines from UK supermarkets. Classic Coca-Cola, which is strictly regulated world-wide, was used to check agreement between analysers in different countries.

Results: The P content of alcoholic beers in the Saarland selection varied from 12 to 27 mg/dL. There was no association between P and alcohol level. P levels in the non-alcoholic beers tested to date were 9 and 18 mg/dL DAP-free white wines contained 6 to 8 mg/dL P, while reds contained 14 to 20 mg/dL. DAP increased the P level by about 2 mg/dL for every 100 mg/L added to the wine must. Much higher P levels in the supermarket wines (up to 31 mg/dL) suggest routine addition of 500 to 700 mg/L DAP.

Conclusions: Phytic acid in cereal grains and grape pips provides P for the seedlings. Inorganic P is released from this indigestible molecule by the enzyme phytase during malting (sprouting) and fermentation. Biological variation, differences in production that affect the breakdown of phytic acid and addition of DAP contribute to the wide range of P content in beer and wines. Until appropriate labelling becomes mandatory, tables of measured P content by brand could help patients trying to restrict their P intake.

FR-PO907

Recruitment and Retention to a Randomised Trial of Low versus High Serum Phosphate Levels in Hemodialysis Patients

Ramya Bhargava,[1] Paul E. Brenchley,[1] Philip A. Kalra,[2] Alastair J. Hutchison.[1] *[1]Manchester Royal Infirmary, United Kingdom; [2]Salford Royal Hospital, United Kingdom.*

Background: High phosphate is linked with increased mortality in dialysis patients in retrospective observational studies but cause and effect is unproven. A large scale RCT of high versus low serum phosphate would be required to determine whether serum phosphate reduction improves length or quality of life of dialysis patients. We performed a feasibility study to investigate whether such a large scale RCT might be possible in the future.

Methods: After consent, 104 HD patients were randomized to low (2.5-4.4 mg/dL) or high phosphate (5.6-7.5 mg/dL) groups. Non-calcium binders, and an adherence self-help program were used to titrate to target PO4 over 8 weeks. A 10 month maintenance period followed. Primary endpoint; % patient months within target range over 10 months. Secondary end points: % nephrologists agreeing to enrol patients, % eligible patients willing to participate, drop-out rate over 12 months, pill burden per subject.

Results: 768 HD patients were screened, 263 suitable, 202 approached, 128 consented, and 104 randomised (13.5% of screened). 21 of 24 nephrologists (87.5%) agreed to enrol patients after assessing the protocol.

	High PO4	Low PO4
Randomised N	51	53
Completed follow-up N, (%)	31 (60.8)	38 (71.7)
Premature trial exit N, (%)	20 (39.2)	15 (28.3)
Transplanted N, (%)	4 (7.8)	1 (1.9)
Deceased N, (%)	8 (15.7)	2 (3.8)
Withdrew consent N, (%)	4 (7.8)	8 (15.1)
Withdrawn by investigator N	4 (7.8)	1 (1.9)
% pt mths within PO4 range	49.5	35.7

Conclusions: Less than 50% of PO4 levels were within target range over 10 months, and this will be analyzed as time-averaged results. More patients withdrew consent in the low PO4 group, with GI side-effects plus high pill burden being possible contributory factors. 65% patients completed the study with a drop-out rate of 35%. Drop-out due to death was substantially greater in the high PO4 group, but randomization was not stratified for other risk factors, and the overall mortality rate of 10% is lower than the expected dialysis rate of 13-17% per annum.

FR-PO908

Randomization to High or Low Phosphate Control in Hemodialysis: Is Such a Study Feasible?

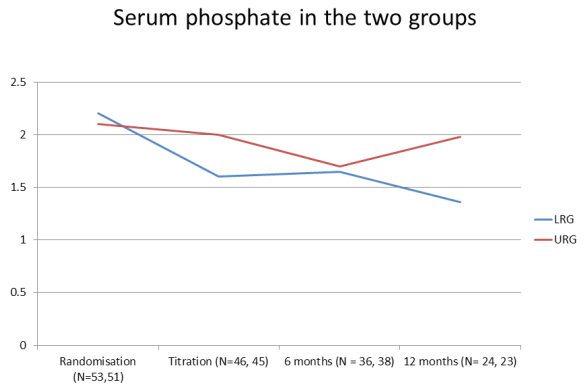
Ramya Bhargava,[1] Paul E. Brenchley,[1] Philip A. Kalra,[2] Alastair J. Hutchison.[1] *[1]Manchester Royal Infirmary, United Kingdom; [2]Salford Royal Hospital, United Kingdom.*

Background: High phosphate is linked with increased mortality in dialysis patients in retrospective observational studies but cause and effect is unproven. A large scale RCT of high versus low serum phosphate would be required to determine whether serum phosphate reduction improves length or quality of life of dialysis patients. We performed a feasibility study to investigate whether such a large scale RCT might be possible in the future.

Methods: From a pool of 768 HD patients, 104 were suitable and consented to a binder washout period, and were randomized to low phosphate (2.5 to 4.4 mg/dL) or high phosphate (5.6 to 7.5 mg/dL) groups. Subjects were titrated to target over 8 weeks with lanthanum or sevelamer binders only, then followed for 10 months. The pill burden in each group and secondary hyperparathyroidism were assessed. Serum albumin as a measure of nutritional status was recorded.

Results:

	HRG	LRG	P value
Number randomised	51	53	
Randomisation PO4 (mg/dL)	2.1+/- 0.1	2.2 +/- 0.1	
Week 8 PO4 (mg/dL)	2.0 +/- 0.4	1.6 +/- 0.4	<0.05
Randomization PTH(pg/ml)	436 +/- 62	424 +/- 54	
Week 8 PTH(pg/ml)	362 +/- 258	472 +/- 380	
Randomization Albumin(g/L)	32 +/- 0.8	32 +/- 0.8	
Week 8 Albumin(g/L)	34 +/- 0.6	34 +/- 0.7	
Week 8 Pill burden	6 (2,15)	1.5 (0,9)	<0.05
Mortality	8	2	



Conclusions: 1. Statistically significant separation in serum phosphate was achieved between the two groups (fig 1) with no apparent increase in secondary hyperparathyroidism. 3 patients in the HRG commenced Cinacalcet during the course of the study because serum PTH > 1200mg/dL. 2. As expected, LRG had a significantly larger pill burden than the HRG, with 20 patients in the LRG taking 9 or more binder pills. 3. Despite increased pill burden, albumin levels were not different between groups. 4. Crude mortality 4 times higher in the HRG.

FR-PO909

Efficacy and Safety of PT20: A Novel Iron-Based Phosphate Binder

Geoffrey A. Block,[1] George G. Hon,[2] Nuno Faria,[3] Jonathan Powell.[3] *[1]Denver Nephrologists PC, Denver, CO; [2]Kidney Wellness Center, Long Beach, CA; [3]Human Nutrition Research, Medical Research Council, Cambridge, United Kingdom.*

Background: PT20, a novel iron based phosphate binder (P-binder), has been specifically engineered with adipic acid substitution to improve phosphate binding capacity and affinity of ferric oxides. PT20 has shown high binding affinity for phosphate in preclinical studies.

Methods: Patients were on hemodialysis with serum phosphate (P) levels between 4.0 and 8.0mg/dL plus serum ferritin levels <1000 ng/mL at their screening visit. All patients were then washed out of previous P-binders and required to have an increase in serum P of at least 1.0 mg/dL to enter study. 153 subjects were randomized to either 400mg, 800mg, 1600mg, 3200mg PT20 or placebo, each taken TID with meals for 28 days. Doses were not modified during the treatment period. Primary end point was change in serum P from Baseline to Day 29. Secondary endpoints assessed safety as well as haematological parameters.

Results: PT20 treatment significantly reduced serum P levels and demonstrated a dose response effect (ITT population; p<0.001). All dose groups showed a reduction in mean serum P levels greater than placebo. Mean reduction in P over the 28 days was (mg/dL) 1.36 / 3200mg; 1.29 / 1600mg; 0.59 / 800mg; 0.40 / 400mg and 0.17 / Placebo dose. Limited iron absorption from PT20 was observed across all groups. Adverse events (AE) were mostly GI in nature but generally uncommon and not dose related (diarrhoea (15 and 6%; P binder average and placebo); discoloured faeces (10 and 0 %); Vomiting (4 and 0 %); nausea (4 and 0%); constipation (1 and 11 %)). 12 patients' experienced serious adverse events that were not considered related to PT20.

Conclusions: Use of adipate-modified iron oxide (PT20) resulted in a statistically significant and dose-dependent reduction in serum phosphate over a 28 day period. The safety profile and tolerability were acceptable with AEs being mostly GI in nature, with no pattern of serious adverse events related to treatment. Limited iron absorption from PT20 was observed.

Phase III Study to Investigate the Efficacy, Safety, and Tolerability of PA21 (Sucroferric Oxyhydroxide) Compared with Sevelamer Hydrochloride in Japanese Hemodialysis Patients with Hyperphosphatemia

Fumihiko Koiwa,[1] Masafumi Fukagawa,[2] Keitaro Yokoyama,[3] Tadao Akizawa,[4] Akira Terao.[5] *[1]Div of Nephrology, Dept of Medicine, Showa Univ Fujigaoka Hospital, Yokohama, Japan; [2]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [3]Div of Nephology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; [4]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan; [5]Biostatistics, Faculty of Pharmaceutical Sciences, Josai Univ, Sakado, Japan.*

Background: An open-label, randomized, parallel-group, multicenter, active-controlled phase III study was performed to assess the efficacy, safety, and tolerability of the non-calcium, iron-based phosphate binder PA21 (sucroferric oxyhydroxide: SFOH) vs sevelamer hydrochloride (SEV) in Japanese hemodialysis (HD) patients with hyperphosphatemia.

Methods: In total, 213 patients were randomized to SFOH (750–3000 mg/day; starting dose 750 mg/day; 250 mg tablets; n=108) and SEV (3–9 g/day; starting dose 3 g/day or 6 g/day; 250 mg tablets; n=105) for 12 weeks. Doses were titrated during Weeks 2–8 to reach predefined serum phosphorus (sP) concentrations of 3.5–6.0 mg/dL, but were unchanged during Weeks 8–12.

Results: Mean sP concentrations at the last evaluation were 5.00 mg/dL for SFOH vs 5.34 mg/dL for SEV (between-group difference: -0.34 mg/dL). Moreover, the value was significantly lower in the SFOH compared to the SEV (an analysis of covariance with sP concentrations at Week 0 as a covariate, P = 0.02). The average number of tablets was 4.8 tablets/day for SFOH vs 17.6 tablets/day for SEV.

Conclusions: Study met the non-inferiority primary end point. SFOH showed even a larger serum phosphorus reduction in Japanese HD patients, compared with SEV (p=0.02), and was associated with a lower pill burden and good tolerability.

FR-PO911

Phase III Study to Investigate the Long-Term Efficacy, Safety, and Tolerability of PA21 (Sucroferric Oxyhydroxide) in Japanese Hemodialysis Patients with Hyperphosphatemia

Fumihiko Koiwa,[1] Masafumi Fukagawa,[2] Keitaro Yokoyama,[3] Tadao Akizawa.[4] *[1]Div of Nephrology, Dept of Medicine, Showa Univ Fujigaoka Hospital, Yokohama, Japan; [2]Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Japan; [3]Div of Nephology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; [4]Div of Nephrology, Dept of Medicine, Showa Univ School of Medicine, Tokyo, Japan.*

Background: An open-label, multicenter study was performed to assess the long-term efficacy, safety, and tolerability of the non-calcium, iron-based phosphate binder PA21 (sucroferric oxyhydroxide: SFOH) after 52-weeks of treatment in Japanese hemodialysis (HD) patients with hyperphosphatemia.

Methods: In total, 161 patients were treated with SFOH (750–3000 mg/day; starting dose 750 mg/day; available as 250 mg and 500 mg tablets). SFOH was administered at Week 0, after treatment with any prior phosphate binders had been discontinued. Doses of SFOH were titrated to maintain predefined serum phosphorus (sP) concentrations of 3.5–6.0 mg/dL.

Results: Mean sP concentrations decreased from 5.46 mg/dL at Week 0 to 5.00 mg/dL at the last evaluation. Mean sP concentrations were maintained within the target range of 3.5–6.0 mg/dL throughout the 52-weeks treatment period. The average number of SFOH tablets was 3.3 tablets/day, and the average dose of SFOH was 1,141 mg/day. Overall, the incidence of adverse events and adverse drug reactions was 94.4% and 32.9%, respectively. Frequently observed adverse drug reactions were diarrhea (22.4%) and constipation (2.5%); no severe diarrhea or constipation was reported. Despite slight increases in serum ferritin and transferrin saturation, no clinical signs of iron accumulation or overload were observed at 52 weeks.

Conclusions: SFOH demonstrated a sustained sP-lowering effect 52-weeks of treatment in Japanese HD patients, and was associated with a low pill burden and good tolerability.

FR-PO912

Improved Serum Phosphorus Control and Decreased Phosphate Binder Pill Burden Amongst African American Hemodialysis Patients Taking Sucroferric Oxyhydroxide

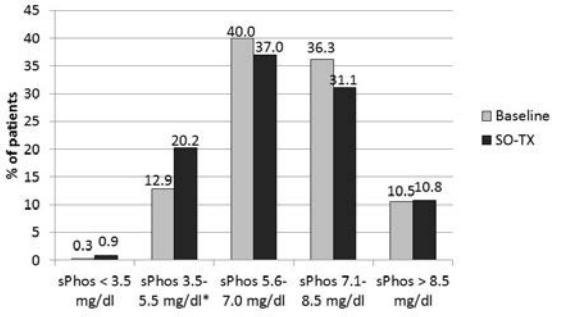
Linda H. Ficociello, Lin Ma, Vidhya Parameswaran, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: A retrospective database study was conducted on the real-world effectiveness of sucroferric oxyhydroxide (SO) in controlling serum phosphorus (sPhos) among hemodialysis (HD) patients (pts). This analysis focuses on the subset of patients who self-reported race as Black or African American.

Methods: All patients were prescribed SO as part of standard care at FMCNA clinics and had ³1 sPhos measured during SO use. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder pills per day (PPD) were assessed 3-months before (baseline; BL) and 3-months during SO treatment (SO-TX).

Results: On average, pts (n=1015) were 51 years old with a dialysis vintage of 5.2 years and hyperphosphatemia (BL sPhos= 6.93 mg/dl). BL phosphate binder used were: sevelamer (52.1%), calcium acetate (26.3%), calcium carbonate (4.7%), lanthanum (7.2%), dual PB therapy (4.1%) and no PB specified (5.5%). As shown in Figure, pts in-range for sPhos increased from 12.9 to 20.2% (57%, p<0.001). Significant decreases in mean sPhos (6.93 to 6.73 mg/dl) and PPD (8.5 to 3.7 pills) were observed (p<0.001 for both). There was minimal change in sCa (9.3 to 9.27 mg/dl, p=0.05) or iPTH (685.3 to 700.9 pg/ml, p=0.15). Iron indices increased (FER: 1010.7 to 1076.3 ng/ml, p<0.001; TSAT: 33.6 to 34.8%, p<0.001). In pts not receiving IV Iron, changes in TSAT (35.1 to 34.2%) and FER (1245.1 to 1193.6 ng/ml) were not significant.

Distribution of sPhos during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up for African American HD patients (N=1015)



*Change in %in-range and %out of range baseline compared to SO-treated follow-up, p <0.001

Conclusions: In a cohort of African American hemodialysis patients prescribed sucroferric oxyhydroxide, a 57% increase in patients with in-range (3.5-5.5 mg/dl) serum phosphorus (p<0.001) along with a decrease in pill burden (4.8 fewer pills, p<0.001) was observed.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

FR-PO913

Real-World Use of Sucroferric Oxyhydroxide in Hemodialysis Patients: Changes in Serum Phosphorus Control and Phosphate Binder Pill Burden

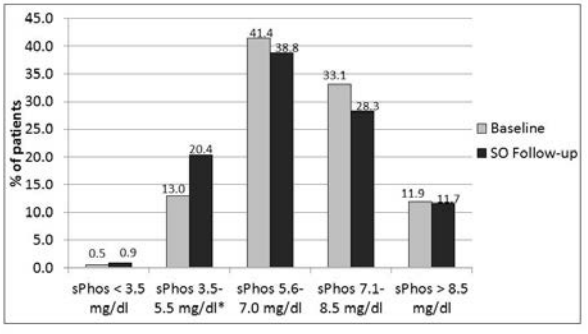
Linda H. Ficociello, Lin Ma, Vidhya Parameswaran, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: Approximately 40% of US dialysis patients (pts) do not achieve serum phosphorus (sPhos) goals (US-DOPPS Practice Monitor, 4/2015). This retrospective database analysis assessed the real-world effectiveness of sucroferric oxyhydroxide (SO) to control sPhos in hemodialysis (HD) pts.

Methods: In-center HD pts prescribed SO as part of routine clinical practice at FMCNA clinics with ³1 sPhos during SO use were included. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder (PB) pills per day (PPD) were assessed 3-months before (baseline) and 3-months during SO treatment (follow-up).

Results: On average, pts (n=3151) were 54 years old with 4.3 years dialysis vintage and hyperphosphatemia (baseline sPhos = 6.94 mg/dl). PB prescribed at baseline were: sevelamer (47%), calcium acetate (26%), calcium carbonate (6%), lanthanum (7%), other PB (.1%), dual PB (7%), and no PB specified (7%). Pts with in-range sPhos (3.5-5.5 mg/dl) increased from 13 to 20.4% (57% increase). Mean sPhos (6.94 to 6.73 mg/dl, p<0.001) and mean sCa (9.21 to 9.18 mg/dl, p=0.003) decreased significantly. IPTH changed minimally (594.6 to 604.9 pg/ml, p=0.06). TSAT and FER increased (both p<0.001) from 33.6 to 35.1% and 947.9 to 1005.3 ng/ml, respectively. In pts not receiving IV iron, there was no significant change in TSAT (35.5% to 34.6%) and minimal decrease in FER (1122.9 to 1063.7 ng/ml, p=0.008). PB PPD decreased by 4.7 pills (8.4 to 3.7 pills, p<0.001).

Distribution of sPhos during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up for HD patients (N=3151)



*Change in %in-range and %out of range baseline compared to SO Follow-up, p <0.001

Conclusions: In a large HD patient cohort prescribed sucroferric oxyhydroxide as part of routine clinical care, in-range serum phosphorus increased by 57% (13 to 20.4%, p<0.001) and mean pills per day decreased by 4.7 pills (8.4 to 3.7 pills, p<0.001).

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

FR-PO914

Serum Phosphorus Control and Phosphate Binder Pill Burden Among Hemodialysis Patients Who Switched from Calcium Based Phosphate Binders to Sucroferric Oxyhydroxide

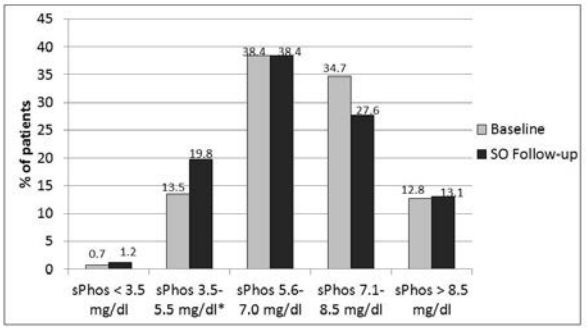
Vidhya Parameswaran, Lin Ma, Linda H. Ficociello, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America, Waltham, MA.*

Background: A retrospective database analysis of in-center hemodialysis (HD) patients (pts) who switched from calcium-based phosphate binders (PB) to sucroferric oxyhydroxide (SO) was conducted to study the real-world effectiveness of SO in controlling serum phosphorus (sPhos).

Methods: In-center HD pts who had ≥ 1 sPhos measured during SO treatment and switched from calcium-based PB were included. Comparisons were made between baseline (3 months prior to SO) and follow-up (3 months during SO) levels of sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pills per day (PPD).

Results: Analyzed pts (n=1011) were, on average, 54 years old with dialysis vintage of 4.5 years and hyperphosphatemia (baseline sPhos=6.98 mg/dl). Prior therapy included 81.7% calcium acetate and 18.3% calcium carbonate. There was a significant decrease in sPhos (6.98 to 6.77 mg/dl, p<0.001) and PB PPD (8.2 to 3.7 pills, p<0.001). A 47% increase (13.5% to 19.8%, p<0.001) in the number of pts with in-range sPhos (3.5-5.5 mg/dl) was observed. Levels of iPTH (539.3 to 552.9 pg/ml) and sCa (9.12 to 9.1 mg/dl) did not change significantly. Significant differences in TSAT (34.0 to 34.8%, p-value=0.007) and FER (931.7 to 973.1 ng/ml, p<0.001) were observed. In pts not receiving IV iron (n=103), there were no significant changes in TSAT (34.5% to 33.4%) and FER (1039 to 1003.4 ng/ml).

Distribution of sPhos during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up for HD patients who switched from calcium-based PB (N=1011)



*Change in %in-range and %out of range baseline compared to SO Follow-up, p =<0.001

Conclusions: In a HD cohort switched from calcium-based binders to sucroferric oxyhydroxide as part of routine clinical care, a 47% increase (p<0.001) in the number of patients with in-range serum phosphorus and reduction of serum phosphorus (0.21 mg/dl, p<0.001) was observed. Pill burden decreased significantly (4.6 fewer pills, p<0.001).

Phosphate Binder VS-505 Prevents Hyperphosphatemia from Altering Aortic Gene Expression in 5/6 Nephrectomized Uremic Rats

J. Ruth Wu-Wong,[1] Xiaoan Ruan,[2] Yung-wu Chen,[1] Jerry Wessale.[1] *[1]Vidasym; [2]Jackson Lab.*

Background: Chronic kidney disease (CKD) patients are known to have impaired vascular function. Clinical studies have linked hyperphosphatemia to a higher cardiovascular mortality in CKD.

Methods: We compared gene expression profiles in aorta isolated from 5/6 nephrectomized (NX) uremic Sprague Dawley rats fed a normal diet vs. a high phosphate (Pi) diet. Real-time RT-PCR analysis was conducted on selected genes in aorta prepared from 5/6 NX uremic rats on a high Pi diet for 4 weeks treated with or without the phosphate binder VS-505, a non-absorbable, calcium- and aluminum-free, chemically-modified, plant-derived polymer currently being evaluated in hemodialysis patients.

Results: An increase in serum Pi was observed in uremic rats on the special diet (3.92 ± 0.42 vs. 3.29 ± 0.55 mmol/L on normal diet). A total of 135 target genes were affected (out of 15923 genes; 2-fold change, p<0.01) by increased serum Pi, with 122 up-regulated and 13 down-regulated. Target genes fell into various categories including carboxylic acid metabolism, lipid metabolism, mitochondrion, and oxidoreductase activity. In a separate study, VS-505 (0.2 - 5% by weight in food) prevented the increase in serum Pi (3.06 ± 0.30 mmol/L in the 5% VS-505 group vs. 3.74 ± 0.68 mmol/L in the vehicle-treated group, p<0.01), and it increased fecal Pi in a dose-dependent manner in the uremic rats on high-Pi diet (2.48 ± 0.60 mmol/24 hr in the 5% VS-505 group at Week 4 vs. 0.84 ± 0.55 mmol/24 hr at pre-dosing, p<0.001). VS-505 did not affect food/water consumption, feces appearance, intestine histomorphology and NPT2b gene expression. VS-505 treatment prevented the effects of hyperphosphatemia on altering the expression of aortic genes related to oxidative stress and inflammation such as activin A receptor-type 1c, glycogen synthase 2, heat shock 70KD protein 1A, stearoyl coenzyme A desaturase 1, and uncoupling protein 1.

Conclusions: These results suggest that hyperphosphatemia affects aortic gene expression linked to oxidative stress and inflammation, and that the adverse cardiovascular effects of high serum Pi may be prevented by oral treatment with the phosphate binder VS-505.

FR-PO916

Fractional Excretion of Phosphorus Misrepresents Hormonal Effects on Phosphate Reabsorption in Chronic Kidney Disease

Kenneth R. Phelps,[1,2] Darius Mason,[1,2,3] Sun J. Kang.[1] *[1]Stratton VAMC, Albany, NY; [2]Albany Medical College, Albany, NY; [3]Albany College of Pharmacy and Health Sciences, Albany, NY.*

Background: The serum P concentration ($[P]_s$) = E_P/C_{cr} + TR_P/C_{cr}, where E_P/C_{cr} and TR_P/C_{cr} are rates of urinary excretion and tubular reabsorption of P per volume of filtrate. E_P/C_{cr} is proportional to filtrate [P] in the cortical distal nephron ($[P]_f$); we have argued that [PTH] correlates with E_P/C_{cr} for this reason in CKD. Fractional excretion of P (FE_P), usually calculated as $[P]_u[cr]_s/[P]_s[cr]_u$, also equals $1/\{1 + (TR_P/C_{cr})/(E_P/C_{cr})\}$. Since E_P equals influx of P (I_P), the second expression shows that both I_P and TR_P determine FE_P. We hypothesized that FE_P correlates with [PTH] and [FGF23] in CKD because I_P affects all 3 variables.

Methods: We measured fasting $[cr]_s$, $[cr]_u$, $[P]_s$, $[P]_u$, [PTH]1-84 (Scantibodies) and intact [FGF23] (Immutopics) in 30 patients with stages 3-4 CKD. We calculated E_P/C_{cr} as $[P]_u[cr]_s/[cr]_u$, TR_P/C_{cr} as $[P]_s - E_P/C_{cr}$, and FE_P as $[P]_u[cr]_s/[P]_s[cr]_u$. We performed simple linear regressions as in the table and a multilinear regression of FE_P on E_P/C_{cr}, TR_P/C_{cr}, [PTH], and [FGF23].

Results: FE_P correlated directly with [PTH], [FGF23], and E_P/C_{cr}, and inversely with TR_P/C_{cr}. [PTH] and [FGF23] correlated directly with E_P/C_{cr}. TR_P/C_{cr} was not associated with [PTH] or [FGF23]. In the multilinear regression, E_P/C_{cr} and TR_P/C_{cr} caused > 90% of variation in FE_P; [PTH] and [FGF23] did not contribute significantly.

Regression	R^2	*P*	Regression	R^2	*P*
FE_P on [PTH]	0.24	0.006	[PTH] on E_P/C_{cr}	0.28	0.003
FE_P on [FGF23]	0.17	0.02	[FGF23] on E_P/C_{cr}	0.26	0.004
FE_P on E_P/C_{cr}	0.76	< 0.001	TR_P/C_{cr} on [PTH]	0.07	0.15
FE_P on TR_P/C_{cr}	0.34	< 0.001	TR_P/C_{cr} on [FGF23]	0.001	0.84

Conclusions: TR_P/C_{cr} was unrelated to [PTH] and [FGF23] even though both hormones reduce P reabsorption. Although FE_P varied inversely with TR_P/C_{cr}, correlations of FE_P with [PTH] and [FGF23] did not result from effects of the hormones on TR_P/C_{cr}, and therefore did not reflect quantitative relationships between hormone concentrations and P reabsorption. The correlations occurred because FE_P, [PTH], and [FGF23] were associated with E_P/C_{cr}. FE_P should not be used to relate P reabsorption to hormones in CKD.

FR-PO917

Attributes of the Walton-Bijvoet Nomogram at Normal and Reduced Glomerular Filtration Rate

Kenneth R. Phelps,[1,2] Darius Mason,[1,2,3] Sun J. Kang.[1] *[1]Stratton VAMC, Albany, NY; [2]Albany Medical College, Albany, NY; [3]Albany College of Pharmacy and Health Sciences, Albany, NY.*

Background: The serum P concentration ($[P]_s$) is the sum of E_P/C_{cr} and TR_P/C_{cr} (urinary excretion and tubular reabsorption of P per volume of filtrate). In Bijvoet's infusion studies, observed TR_P/C_{cr} equaled maximum TR_P/C_{cr} (Tm_P/GFR) at fasting fractional P excretion (FE_P) > 20%; as FE_P fell, (Tm_P/GFR) – (TR_P/C_{cr}) rose. These observations were incorporated into a nomogram that derives Tm_P/GFR from $[P]_s$ and FE_P. Although the nomogram was based on data obtained at GFR > 40 mL/min, it is used to assess P reabsorption in CKD. We examined this practice.

Methods: We collected fasting morning serum (s) and urine (u) from 30 patients with stages 3-4 CKD and 28 controls with MDRD eGFR > 60. We calculated E_P/C_{cr} as $[P]_u[cr]_s/[cr]_u$, TR_P/C_{cr} as $[P]_s - E_P/C_{cr}$, and FE_P as $[P]_u[cr]_s/[cr]_u[P]_s$. After ascertaining Tm_P/GFR from the nomogram, we calculated (Tm_P/GFR)/$[P]_s$), ($Tm_P/GFR - TR_P/C_{cr}$) and (Tm_P/GFR)/(TR_P/C_{cr}). We performed group comparisons with the Mann-Whitney U test.

Results: In CKD, E_P/C_{cr} and FE_P were higher, and eGFR, TR_P/C_{cr}, Tm_P/GFR, (Tm_P/GFR)/$[P]_s$, (TR_P/C_{cr})/(E_P/C_{cr}), ($Tm_P/GFR - TR_P/C_{cr}$), and (Tm_P/GFR)/(TR_P/C_{cr}) were lower than in controls. $[P]_s$ was not different in the 2 groups. In CKD, FE_P was > 20% in 27/30 patients; mean ($Tm_P/GFR - TR_P/C_{cr}$) and (Tm_P/GFR)/(TR_P/C_{cr}) approximated 0 and 1, respectively.

Parameter	CKD[a]	Controls[a]
eGFR, ml/min/1.73m^2	29.5 (1.7)	86.0 (1.9)
$[P]_s$, mg/dL	3.5 (0.1)	3.4 (0.1)
E_P/C_{cr}, mg/dL	1.4 (0.1)	0.4 (0.03)
TR_P/C_{cr}, mg/dL ($[P]_s$ - E_P/C_{cr})	**2.2 (0.1)**	**3.1 (0.1)**
(TR_P/C_{cr})/(E_P/C_{cr})	2.1 (0.3)	8.8 (0.9)
FE_P, %	40 (3)	11 (0.7)
Tm_P/GFR, mg/dL (nomogram)	**2.1 (0.1)**	**3.4 (0.1)**
(Tm_P/GFR)/$[P]_s$	0.63 (0.03)	0.97 (0.02)
(Tm_P/GFR) - (TR_P/C_{cr}), mg/dL	0.02 (0.01)	0.3 (0.05)
(Tm_P/GFR)/(TR_P/C_{cr})	1.0 (0.003)	1.1 (0.02)

[a]Values are mean (SEM). $P = 0.73$ for $[P]_s$ and < 0.001 for all other comparisons.

Conclusions: FE_P is > 20% at (TR_P/C_{cr})/(E_P/C_{cr}) < 4. In this circumstance, Tm_P/GFR = TR_P/C_{cr} = $[P]_s - E_P/C_{cr}$ whether E_P/C_{cr} is increased by P influx or low C_{cr}. Use of the nomogram and calculation of TR_P/C_{cr} require the same variables. In CKD, the nomogram is accurate but unnecessary if (TR_P/C_{cr})/(E_P/C_{cr}) is < 4.

Role of KHSRP and Pin1 in Mediating the Parathyroid Hormone Response in the Proximal Tubule

Rebecca Murray,[1,2] Michael Merchant,[2] Syed J. Khundmiri,[1,2,3] Barbara Clark,[4] Eleanor D. Lederer.[1,2,3] *[1]Physiology & Biophysics, Univ of Louisville, Louisville, KY; [2]Medicine, Univ of Louisville, Louisville, KY; [3]Robley Rex VAMC, Louisville, KY; [4]Biochemistry & Molecular Biology, Univ of Louisville, Louisville, KY.*

Background: Parathyroid hormone (PTH) regulates the type IIa sodium-phosphate cotransporter (Npt2a), the major regulated proximal tubule phosphate transporter, at both the protein and mRNA level. We previously identified KHSRP as a PTH-responsive phospho-protein that binds Npt2a mRNA and may mediate its degradation. Pin1, a peptidyl- prolyl isomerase, is the upstream regulator of KHSRP function and localization. Non-phosphorylated Pin1 binds KHSRP, promoting KHSRP dephosphorylation and maintaining its cytosolic localization. We hypothesize that PTH stimulates Npt2a mRNA destabilization through PKA-mediated phosphorylation of Pin1.

Methods: To address this hypothesis, we treated opossum kidney (OK) cells, a proximal tubule cell line, with 100nM PTH or 10μM 8-bromo-cAMP (8-Br [to directly activate PKA]) in the presence or absence of 1μM H-89 (a PKA inhibitor).

Results: 2h PTH induced a 2.5-fold increase in Pin1 phosphorylation. IP of KHSRP followed by immunoblot for Pin1 showed that Pin1 associates with KHSRP under basal conditions, but not following 2h PTH or 8-Br treatment. Pre-treatment with H-89 blocked the PTH/8-Br-induced disassociation. 2h PTH did not alter total expression of KHSRP, but stimulated its translocation to the nucleus.

Conclusions: We conclude that PTH-mediated destabilization of Npt2a mRNA likely involves PKA-mediated regulation of Pin1 and KHSRP activity. Funding provided by VA to EDL.

Phosphate Depletion-Induced Metabolic Acidosis and Alkali Urine May Be Caused by Inappropriate Stimulation of Apical Cl^-/HCO_3^- Exchanger (Pendrin) in Mouse Kidney Type B Intercalated Cells (IC-B)

Yukiko Yasuoka,[1,2] Tomomi Oshima,[1] Yuichi Sato,[3] Hiroshi Nonoguchi,[4] Katsumasa Kawahara.[1,2] *[1]Physiol., Kitasato U. Sch. of Med., Sagamihara, Japan; [2]Cell & Mol. Physiol., Kitasato U. Grad. Sch. of Med. Sci., Sagamihara, Japan; [3]Mol. Diag., Kitasato U. Grad. Sch. of Med. Sci., Sagamihara, Japan; [4]Internal Med., Kitasato U. Medical Center, Kitamoto, Japan.*

Background: Mice treated with a low phosphate (P_i) diet can maintain normal levels of plasma P_i concentration via stimulation of bone reabsorption, but show hypercalcemia, hypercalciuria, and hypophosphaturia. Recently, the Ca-sensing receptor (CaSR) was found to be localized in the basolateral membrane of IC-B as well as in the thick ascending limb of Henle's loop (Yasuoka et al, 2014). This study was aimed to determine whether hypercalcemia and/or hypercalciuria affect urine pH as expected in mice treated with either dietary P_i depletion or $CaCl_2$-loading.

Methods: C57Bl/6J mice (10 wks, male) were divided into three groups: (1) normal diet (1% P_i, n=6), (2) low-P_i (LP) diet (0.02% P_i, n=4), (3) $CaCl_2$-loading (1% P_i, +1% Ca ($CaCl_2$), n=6). All diets contain 1% Ca ($CaCO_3$). On day 7, a 24-hr urine, blood, and kidney samples were collected.

Results: Serum and urinary Ca were markedly and significantly increased in the LP and $CaCl_2$ groups [serum, 9.1 and 8.9 mg/dl; and urine, 2,400 and 2,140 μg/day], compared with control [serum, 7.6 mg/dl; urine, 108 μg/day]. Although serum pH decreased similarly and significantly to 7.25 and 7.20 in both groups, pH of the urine decreased to 5.6 ($P < 0.05$) in the $CaCl_2$ group and, surprisingly, increased to 7.4 ($P < 0.05$) in the LP group (control, serum pH 7.35; urine, pH 6.3). Kidney histology and immunohistochemistry showed that

the IC-A cell height and basolateral Cl^-/HCO_3^- exchanger type 1 (AE1) staining significantly increased in the $CaCl_2$ group, whereas the IC-B cell height and apical Pendrin and basolateral AE4 staining significantly increased in the LP group.

Conclusions: P_i-depletion induced metabolic acidosis may be due to imbalanced urinary alkalinization and acid absorption caused by inappropriate stimulation of Pendrin and AE4 through the hypercalcemia-induced activation of the basolateral CaSR in IC-B.

FR-PO920

MUCIN1 Increases Renal Calcium Channel TRPV5 Activity to Enhance Calcium Reabsorption in a Galectin-3 Dependent Fashion Matthias Wolf,[1] Mingzhu Nie,[1] Zhufeng Yang,[2] Jie Liu,[1] Denise K. Marciano,[2] Manjot S. Bal.[1] *[1]Pediatrics, UTSW Medical Center, Dallas, TX; [2]Internal Medicine, UTSW Medical Center, Dallas, TX.*

Background: *MUCIN1* (*MUC1)* mutations cause autosomal dominant tubulo-interstitial kidney disease (ADTKD-MUC1), a condition similar to a nephropathy caused by *Uromodulin* (*UMOD*) mutations (ADTKD-UMOD). We previously showed that UMOD may protect against calcium-containing kidney stones by increasing TRPV5 cell surface abundance and tubular calcium reabsorption, which may decrease the risk of urinary supersaturation. The role of MUC1 in kidney is unclear. As UMOD and MUC1 share characteristics regarding disease phenotype, protein function, and structure, we examined the hypothesis that MUC1 enhances TRPV5 channel activity.

Methods: We expressed TRPV5 and MUC1 variants in HEK293 cells and studied TRPV5 current density by whole-cell patch-clamp recording.

Results: MUC1 coexpressed with TRPV5 resulted in a higher TRPV5 current density compared to mutant MUC1+C or control. MUC1 increased TRPV5 current density when applied extracellularly and required TRPV5 N-glycan for upregulation. Immunofluorescence imaging showed apical MUC1 expression along the distal nephron which is compatible with TRPV5 regulation in DCT. To test if MUC1 affects TRPV5 endocytosis, we tested if MUC1 upregulates TRPV5 in caveolin-1 deficient fibroblasts, as TRPV5 undergoes endocytosis via caveolin-1. While MUC1 alone had no effect, cotransfection of recombinant caveolin-1 with MUC1 restored TRPV5 upregulation by MUC1. The extracellular domain of MUC1 contains variable number tandem repeats (VNTRs) which bind galectin-3, a lectin involved in lattice formation of channels. Using galectin-3 siRNA, we identified galectin-3 as a prerequisite for TRPV5 upregulation by MUC1. This was confirmed by the inability of MUC1 lacking VNTR to upregulate TRPV5. In urine samples of patients with calcium-containing kidney stones we found less urinary MUC1 compared to control individuals.

Conclusions: MUC1 upregulates TRPV5 by extracellular lattice formation with TRPV5 N-glycan via galectin-3 which impairs TRPV5 channel endocytosis. These data are consistent with MUC1 contributing to protection against calcium-containing kidney stones.

FR-PO921

NCC Activty Modulation as a Mechanism for PTH Regulation of DCT Calcium Transport Benjamin S. Ko,[1] Robert S. Hoover.[2] *[1]Dept of Medicine, Univ of Chicago, Chicago, IL; [2]Dept of Medicine, Emory Univ, Atlanta, GA.*

Background: The distal convoluted tubule (DCT) is a major site of both calcium and sodium transport. While altered DCT calcium handling is not required for thiazide-induced hypocalciuria, studies have documented increased DCT calcium reabsorption in response to thiazide administration. This suggests that DCT sodium transport does affect DCT calcium transport, and while thiazide induced hypocalciuria is due to a proximal effect, modulation of NCC activity may affect DCT calcium transport by TRPV5. Since parathyroid hormone (PTH) is known to increase TRPV5 activity and decrease NCC activity, we theorized that decreased NCC-mediated sodium reabsorption may contribute to the enhanced TRPV5 calcium reabsorption seen with PTH administration.

Methods: Radiotracer uptake and biotinylation in mDCT15 cells were used to measure sodium and calcium uptake as well as surface expression of NCC and TRPV5.

Results: mDCT15 cells expressed ruthenium red sensitive $^{45}Ca^{2+}$ uptake of 5.9±0.2 nmol/mg/min and surface expressed TRPV5. PTH increased $^{45}Ca^{2+}$ uptake to 8.8±0.7 nmol/mg/min (n=4, $p<0.01$ compared to control) and decreased NCC activity from 75.4±2.7 to 20.3±1.3 nmol/mg/min (n=4, $p<0.01$ compared to control). Knockdown of RasGRP1, the pathway by which PTH affects NCC, had no baseline effect on $^{45}Ca^{2+}$ uptake but significantly attenuated the increased $^{45}Ca^{2+}$ uptake response to PTH from a 45% increase (6.0±0.2 to 8.7±0.4 nmol/mg/min) in non-targeting controls to only a 20% increase (6.1±0.1 to 7.3±0.2 nmol/mg/min (n=4, $p<0.01$ compared to non-targeting treated groups)). Inhibition of PKC and PKA, the known pathways by which PTH acts upon TRPV5, resulted in further attenuation of the PTH effect.

Conclusions: Here, through the use of a cell model with native NCC and TRPV5 activity, we report that modulation of NCC activity does indeed contribute to the TRPV5 response to PTH, implying a role for hormonal modulation of NCC activity in distal calcium handling. Further study is needed to determine the mechanism for these findings.

FR-PO922

How Disruption of Distal Nephron Salt Reabsorption Causes Calcium Wasting, Tubule Calcification and Skeletal Changes Sharon L. Barone,[1,2] Jie Xu,[1] Mujan Varasteh kia,[1] Saeed Alshahrani,[1] Marybeth Brooks,[1] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Internal Medicine, Univ of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH.*

Background: Carbonic anhydrase II/sodium chloride co-transporter (NCC) and pendrin/NCC double knockout mice (dKO) develop salt wasting and are growth retarded. We propose that the disruption of sodium and chloride reabsorption in these mice causes phosphate and calcium wasting and leads to bone and skeletal anomalies.

Methods: Renal alterations that lead to distorted calcium and phosphate reabsorption and contribute to tubular calcification and growth retardation in the dKO mice were examined.

Results: dKO mice are volume depleted, exhibit kidney hypoperfusion, and have increased urinary calcium and phosphate excretion. These mice also exhibit skeletal anomalies and osteopenia and develop tubular calcium phosphate deposits. Parathyroid hormone (PTH) and fibroblast growth factor-23 (FGF-23) levels are normal in dKO mice. The urinary content of prostaglandin E2 (PGE2) is significantly elevated, along with the expression of microsomal prostaglandin E synthase 1, while the sodium phosphate transporter IIa (NaPi-IIa) is downregulated in the kidneys of dKO mice. qRT-PCR analyses revealed that the expression levels of NKCC2 variants A and F are reduced while NKCC2-B levels are increased in dKO animals. The latter changes lead to decreased NKCC2 activity in the medullary thick limb and increased calcium excretion, while NaPi-IIa downregulation reduces the reabsorption of phosphate in the proximal tubles. Placement of dKO mice on a high salt diet or their treatment with indomethacin corrected the above derangements. These results show an important role for salt wasting and dehydration-induced PGE2 synthesis in renal calcium and phosphate excretion as well as in bone calcium mobilization.

Conclusions: Our studies suggest the presence of PGE2-mediated pathways, which are activated in response to salt wasting and volume contraction and independent of PTH and FGF-23 activity can lead to anomalous mobilization and excretion of calcium and phosphate, and ultimately lead to skeletal abnormalities and growth retardation.

FR-PO923

Hypercalcemia-Induced Natriuresis Is Mediated by Endothelin-1 (ET-1) Natsuko Tokonami, Lydie Cheval, Pascal Houillier. *ERL 8228 – U1138 Équipe 3, Univ Pierre-et-Marie-Curie, Univ Paris Descartes, INSERM, CNRS, and Centre de Recherche des Cordeliers, Paris, France.*

Background: Acute hypercalcemia commonly increases urinary sodium and water excretions. We previously showed that targeting the calcium receptor CaSR does not affect sodium transport in the renal tubule (Loupy, et al., JCI, 2012), suggesting that the natriuretic effect of hypercalcemia does not involve CaSR. Since hypercalcemia increases the renal expression of ET-1, we tested if ET-1 mediates the natriuretic effect of hypercalcemia.

Methods: Forty-two 8 week-old, male C57Bl6 mice were studied. Osmotic minipumps were implanted to infuse hPTH(1-34) and maintain the concentration of PTH to normal range throughout the experiment. Hypercalcemia was induced by the oral administration of dihydrotachysterol (DHT: 7.5mg/kg food/day). Eighteen mice were treated with an ET-1 receptor antagonist, macitentan (Maci, 27mg/kg BW/day), with or without DHT.

Results: On 3rd day of treatment, mice treated by DHT developed hypercalcemia (5.0±0.1 vs 2.4±0.1 mmol/L control mice) and exhibited increased water and sodium excretion as compared to control mice (2.0 ± 0.1 vs 1.4 ± 0.1 mL/day and 46±4 vs 36±2 mmol Na/mmol creatinine, respectively, $p<0.01$ for both). Mice treated with Maci+DHT had similar levels of hypercalcemia and polyuria as mice treated with DHT only. However, mice treated with Maci+DHT showed no increase in urinary sodium excretion. Mice treated with Maci only were similar to control mice. A 3-4 fold increase in the renal level of ET-1 mRNA was observed in mice treated with DHT and Maci+DHT.

Conclusions: Hypercalcemia increases the renal production of ET-1, which is likely responsible for the increase of urinary sodium excretion. In contrast, ET-1 is not involved in hypercalcemia-induced polyuria.

FR-PO924

The Uremic Toxin Indoxyl Sulfate (IS) Activates the Extracellular Regulated Kinase 1/2 (ERK1/2) Pathway in Primary Human Endothelial Cells (ECs) by Stimulating Ca^{2+}-Influx via the Na^+/Ca^{2+} Exchanger (NCX) Luxme Nadarajah, Steven Michael Harwood, Petros Andrikopoulos, Muhammad M. Yaqoob. *William Harvey Research Inst, Barts and the London School of Medicine, London, United Kingdom.*

Background: Cardiovascular complications are a major cause of morbidity/mortality in CKD and endothelial dysfunction is a major contributing factor. The uremic toxin IS accumulates in the plasma of end-stage renal disease (ESRD) patients and causes oxidative stress and endothelial dysfunction. However, the underlying molecular mechanism(s) are largely unknown. We recently reported that Ca^{2+} influx through the ion transporter NCX activated the ERK1/2 pathway in ECs stimulated with thrombin in a reactive oxidant species (ROS)-dependent manner (Andrikopoulos et al., 2015 JBC). In the present study we investigated whether ERK1/2 activation in response to IS also required Ca^{2+}-influx via NCX.

Methods: Primary human umbilical vein endothelial cells (HUVECs) were serum starved in a physiological buffer and preincubated with reverse-mode (Ca^{2+} infux) NCX inhibitors SN-6 or SEA0400 and the general NCX inhibitor ORM-10103. NCX1 protein was knockdown using siRNA. ERK1/2 activation was determined by western blot. $[Ca^{2+}]_i$ was measured in ECs loaded with the fluorescent Ca^{2+} indicator Fluo-4NW.

Results: We report that IS, at concentrations found in the plasma of ESRD patients (25mg/ml) activated the ERK1/2 pathway and extracellular Ca^{2+} was required for activation. Furthermore, inhibitors of reverse-mode NCX suppressed IS-induced activation of ERK1/2 in a time- and dose-dependent manner and attenuated IS-induced Ca^{2+} transients. Knock-down of NCX1 (the main NCX isoform in HUVECs) by siRNA confirmed the pharmacological data.

Conclusions: We propose that Ca^{2+} influx through reverse-mode NCX is required for IS-induced ERK1/2 activation. Given the known role of ERK1/2 activation in the expression of pro-inflammatory molecules such as COX-2 and VCAM-1 in ECs, reverse-mode NCX could be a novel target for improving endothelial function in CKD.

FR-PO925

Chronic Kidney Disease Impairs Myocardial Perfusion and Disturbes Cardiac Calcium Handling Melissa Verkaik,[1,2,4] Maarten Oranje,[2] Desiree Abdurrachim,[3] Pieter M. Ter Wee,[1] Etto C. Eringa,[2] Marc G. Vervloet.[1] *[1]Dept of Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; [2]Dept of Physiology, Inst of Cardiovascular Research ICaR-VU, VU Univ Medical Center, Amsterdam, Netherlands; [3]Biomedical NMR, Dept of Biomedical Engineering, Eindhoven Univ of Technology, Eindhoven, Netherlands; [4]On behalf of the NIGRAM Consortium.*

Background: The molecular and microcirculatory changes that may underlie the increased prevalence of heart failure and cardiac mortality in CKD are ill-defined. We hypothesized that CKD directly impairs both myocardial perfusion and disturbed cardiac diastolic and systolic function due to disturbed calcium fluxes across the myocardial sarcoplasmatic reticulum.

Methods: Eight week old C57Bl/6J mice were subjected to partial nephrectomy (5/6Nx) or sham-surgery, and after 6 weeks mice were subjected to myocardial contrast echocardiography (MCE) to test myocardial perfusion. Cardiac function was assessed using Cine MRI. In single intact cardiomyocytes diastolic and systolic function, as well as intracellular Ca^{2+} transients were measured by fura-2 loaded cardiomyocytes.

Results: No difference was found between groups for heart weights over tibia length, neither for ejection fraction, cardiac output, end diastolic and systolic volume, and E/A ratio. Sham mice increased myocardial blood volume during acetylcholine infusion, which was absent in 5/6Nx mice (D17%, p=0.023). In isolated cardiomyocytes, time to reach systole was increased in 5/6Nx mice (52.3±0.8 vs. 56.7±0.8 ms, p<0.001), which is explained by a decrease in velocity of cytosolic Ca^{2+} increase (78.8±2.2 vs. 66.0±2.0 Fura340/380/s, p<0.001). The removal of Ca^{2+} from cytosol during diastole was slower in 5/6Nx mice (-7.12±0.23 vs. -5.74±0.18 Fura340/380/s, p<0.001), due to reduced phosphorylation of the SERCA-regulating protein phospholamban (p=0.024), as shown by semiquantitative WB.

Conclusions: CKD compromises both myocardial microvascular perfusion reserve, and systolic and diastolic function in cardiomyocytes. Calcium fluxes across the sarcoplasmic membrane are disturbed, due to a reduced amount of phosphorylated phospholamban, which activates the sarcoplasmic reticulum Ca^{2+}channel SERCA.

FR-PO926

Recessive Mutations in SLC34A1 (NaPi-IIa) as a Cause of Idiopathic Infantile Hypercalcemia Karl P. Schlingmann,[1] Birgitta Kranz,[1] Martin Kaufmann,[3] Elisabeth A.M. Cornelissen,[4] René J. Bindels,[5] Asaf Vivante,[6] Robert Kleta,[7] Elena N. Levtchenko,[8] Glenville Jones,[3] Carsten A. Wagner,[2] Martin Konrad.[1] *[1]General Pediatrics, Wilhelms Univ, Munster, Germany; [2]Inst of Physiology, Univ of Zurich, Zurich, Switzerland; [3]Biomedical and Molecular Sciences, Queen's Univ, Kingston, Canada; [4]Pediatric Nephrology, Radboud Univ, Nijmegen, Netherlands; [5]Physiology, Radboud Univ, Nijmegen, Netherlands; [6]Children's Hospital Boston, Boston; [7]Univ College London, London, United Kingdom; [8]Pediatric Nephrology, Univ Hospitals, Leuven, Belgium.*

Background: Idiopathic infantile hypercalcemia (IIH) is characterized by severe hypercalcemia with failure to thrive, vomiting, dehydration, and nephrocalcinosis. Initially, mutations in *CYP24A1* encoding the vitamin D catabolizing enzyme 25-hydroxyvitamin D_3-24-hydroxylase were discovered that lead to an accumulation of active 1,25-$(OH)_2D_3$ with subsequent hypercalcemia and hypercalciuria.

Methods: In a subgroup of IIH patients without mutations in *CYP24A1* we now performed a positional candidate gene approach in order to identify a second IIH gene locus.

Results: We identified a shared homozygous interval on chromosome 5q35 with a maximum LOD score of 6.91. The sequence analysis of *SLC34A1* encoding proximal-tubular sodium-phosphate co-transporter NaPi-IIa revealed recessive mutations in the 4 index cases as well as in 18 additional sporadic IIH patients. The clinical reevaluation revealed renal phosphate wasting but no signs of rickets. Functional studies of mutated NaPi-IIa in Xenopus oocytes and OK cells demonstrated a disturbed membrane trafficking as well as a loss of phosphate transport activity. The reexamination of *Slc34a1* knockout mice highlighted the critical role of phosphate depletion and FGF-23 suppression. In affected patients, clinical and laboratory findings persist after omitting vitamin D prophylaxis but rapidly respond to phosphate supplementation.

Conclusions: Therefore, an early differentiation between *CYP24A1* (24-hydroxylase) and *SLC34A1* (NaPi-IIa) defects appears crucial for a effective therapy in children with IIH.

FR-PO927

Identification of SLC41A3 as a Novel Player in Renal Magnesium Homeostasis Jeroen H.F. De Baaij, Anke Lameris, René J. Bindels, Joost Hoenderop. *Dept of Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Hypomagnesemia is a common clinical cause of muscle cramps, epilepsy and cardiac arrhythmias. In the distal convoluted tubule (DCT) of the kidney, transcellular reabsorption of Mg^{2+} regulates the body Mg^{2+} balance by determining the final urinary Mg^{2+} excretion. In the DCT, Mg^{2+} is reabsorbed from the pro-urine via the apical Mg^{2+} channel TRPM6. Until now, the basolateral Mg^{2+} extrusion mechanism in DCT is still unknown, but recent findings suggest that proteins of the SLC41 family may contribute to cellular Mg^{2+} extrusion. The aim of this study was, therefore, to investigate the role of SLC41A3 in Mg^{2+} homeostasis using the *Slc41a3* knockout mouse.

Methods: The *Slc41a3* knockout mice were studied by serum and urinary electrolyte analysis. To determine the effect of SLC41A3 on intestinal Mg^{2+} absorption, the Mg^{2+} absorption capacity was measured using the stable $^{25}Mg^{2+}$ isotope.

Results: Tissue expression screening was performed by RT-PCR, showing that *Slc41a3* is the only SLC41 isoform with enriched expression in DCT compared to other segments in the kidney. Interestingly, serum and urinary electrolyte determinations demonstrated that *Slc41a3* knockout mice suffer from hypomagnesemia due to renal Mg^{2+} wasting. Serum and urinary Na^+, K^+ and Ca^{2+} levels were not affected. $^{25}Mg^{2+}$ uptake was similar in wild type and knockout mouse, although *Slc41a3* knockout animals exhibited increased intestinal expression of Mg^{2+} transporters *Trpm6* and *Slc41a1*. Remarkably, 10% of the *Slc41a3* knockout mice developed severe unilateral hydronephrosis, as demonstrated by the presence of transitional epithelium lining the fluid cavity. Feeding the *Slc41a3* knockout mice a low Mg^{2+} diet may have instigated the formation of hydronephrosis.

Conclusions: In conclusion, SLC41A3 was established as a new important factor for renal Mg^{2+} handling, suggesting that SLC41A3 is the basolateral Mg^{2+} extrusion mechanism in the DCT. Slc41a3$^{-/-}$ mice provide the first mouse model with isolated hypomagnesemia, without concomitant electrolyte disturbances. In the future, *SLC41A3* mutations should be considered in patients with unilateral hydronephrosis and/or hypomagnesemia.

Dietary Inulin Supplementation Stimulates Magnesium Absorption in Patients with Proton Pump Induced Hypomagnesemia Jeroen H.F. De Baaij,[1] Mark Wilhelm Hess,[1] Joost Hoenderop,[1] Joost P.H. Drenth,[2] René J. Bindels.[1] *[1]Dept of Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Dept of Gastroenterology, Radboud Univ Medical Center, Nijmegen, Netherlands.*

Background: Hypomagnesemia is a common and severe side effect of patients using proton pump inhibitors (PPI), causing severe muscle cramps and depression. Given that PPI-users are dependent on PPIs for gastric acid protection, drug withdrawal or antacid switching is often not possible to prevent hypomagnesemia. This study, therefore, aimed to restore serum Mg^{2+} levels during PPI use by the dietary application of fructose-oligo-saccharide-enriched inulin fibers.

Methods: This clinical trial prospectively determined serum Mg^{2+} concentrations in 133 patients using PPIs. Under maintenance of PPIs, eleven identified cases of PPI-induced hypomagnesemia were exposed to 2 repetitive dietary supplementations with inulin for 14-days each followed by 14-days washout and compared to 10 healthy non-PPI users. The primary endpoint was serum Mg^{2+}. Secondary endpoints were serum Ca^{2+}, K^+, and Na^+ levels.

Results: Hypomagnesemia is present in 13% of the study population. Dietary supplementation with inulin significantly enhanced mean serum Mg^{2+} levels by + 0.1 mmol/L in PPIH patients and by + 0.06 mmol/L in healthy controls. Moreover, in patients with PPIH concomitant treatment effects were observed for serum Ca^{2+} (+ 0.09 mmol/L) and serum K^+ (+ 0.07 mmol/L), no effects were seen on serum Na^+. Patients with PPIH had adequately renal excretion of Mg^{2+} and Ca^{2+}, which increased due to inulin following increases in serum levels. Additionally, two SNPs in TRPM6 (rs3750425 and rs2274924) were identified that cause a 4.75 times higher risk to develop hypomagnesemia.

Conclusions: Inulin fibers are a new promising prebiotic treatment strategy to treat intestinal- and renal-caused hypomagnesemia. For the first time we provide a successful alternative for oral Mg^{2+} supplementation.

FR-PO929

The Distal Convoluted Tubule Plays a Key Role in Tacrolimus-Induced Hypomagnesemia and Hypercalciuria Rebecca A. Lazelle,[1] Sabina K. Jelen,[2] Chao-Ling Yang,[1] Joost Hoenderop,[2] René J. Bindels,[2] David H. Ellison.[1,3] *[1]Div of Nephrology & Hypertension, Oregon Health and Science Univ, Portland, OR; [2]Radboud Inst for Molecular Life Sciences, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Renal Section, Portland VA Medical Center, Portland, OR.*

Background: The immunosuppressive drug tacrolimus, used to prevent graft rejection, often leads to hypomagnesemia and can also cause hypercalciuria. A decrease in renal Mg^{2+} and Ca^{2+} reabsorption is thought to be involved, but the molecular mechanisms are unclear. Tacrolimus requires a binding partner, FKBP12, to inhibit its canonical target, calcineurin. We generated a mouse model in which FKBP12 can be deleted along the

nephron (KS-FKBP12$^{-/-}$). We then tested if either FKBP12 disruption or calcineurin inhibition along the nephron alters the mRNA abundance of renal ion transport proteins leading to hypomagnesemia and hypercalciuria.

Methods: KS-FKBP12$^{-/-}$ mice were generated using an inducible CRE/LOX system driven by the Pax8 promoter. Mice were treated with doxycycline (KS-FKBP12$^{-/-}$) or vehicle (control). We tested the effects of tacrolimus (3 mg/Kg daily for 18 days) on plasma [Mg^{2+}], urinary Ca^{2+} excretion, and mRNA abundance of renal proteins involved in ion transport using metabolic cages, colorimetric assays and qRT-PCR.

Results: As expected, tacrolimus caused hypomagnesemia and hypercalciuria in control mice. Effects which were absent in KS-FKBP12$^{-/-}$ mice ($P<0.05$ 2-Way ANOVA). In control mice, tacrolimus reduced the mRNA abundance of proteins involved in Mg^{2+} and Ca^{2+} transport by the distal convoluted tubule (DCT) including, TRPM6, calbindin-28K and the Sodium Calcium Exchanger-1. In contrast, tacrolimus had no effect in KS-FKBP12$^{-/-}$ mice ($p<0.05$ by 2-way ANOVA). The abundance of mRNA encoding Claudin 16 and 19, thick ascending limb (TAL) proteins involved in Mg^{2+} and Ca^{2+} handling, were not affected by tacrolimus treatment in either group.

Conclusions: Tacrolimus reduces the abundance of mRNA encoding proteins involved in Ca^{2+} and Mg^{2+} transport by the DCT. These effects require FKBP12, suggesting that calcineurin inhibition is essential. The results show that the DCT plays a key role in these troubling side effects.

Regulation of Magnesium Reabsorption and Transient Receptor Potential M6 Channel Activity by Protein Kinase A Signaling Joost Hoenderop,[1] Maxime G. Blanchard,[1] Wararat Kittikulsuth,[2] Anil V. Nair,[1] Jeroen H.F. De Baaij,[1] Jonathan R. Genzen,[3] Donald E. Kohan,[2] René J. Bindels.[1] *[1]Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Nephrology, Univ of Utah, Salt Lake City, UT; [3]Pathology, Univ of Utah, Salt Lake City, UT.*

Background: The transient receptor potential melastatin type 6 (TRPM6) epithelial magnesium (Mg^{2+}) channel participates in Mg^{2+} transport in kidney and intestine. Previous reports have suggested a hormonal cAMP-dependent regulation of Mg^{2+} reabsorption in the kidney. The molecular details of this process are, however, unknown. Adenylate cyclase type 3 (Adcy3) has been shown to colocalize with the Na^+-Cl^- cotransporter (NCC), a marker of the distal convoluted tubule, the principal site of TRPM6 expression.

Methods: Given the critical role of TRPM6 in Mg^{2+} reabsorption, an inducible kidney-specific Adcy3 deletion mouse model was characterised for blood and urinary electrolyte disturbances under normal and low Mg^{2+} diet. Using patch clamp, cell surface biotinylation and Total Internal Reflection Fluorescence (TIRF) live cell imaging of transfected HEK293 cells TRPM6 channel activity was measured.

Results: Urinary Mg^{2+} excretion was increased (~1.7-fold) in AC3 deleted mice compared to controls where as serum Mg^{2+} concentrations were not different. Renal TRPM6 mRNA levels were increased by ~2-fold in AC3 deleted mice. Serum Mg^{2+} was significantly lower in AC3 deleted animals for 7 days on the low Mg^{2+} diet compared to the control animals. In HEK293 cells, it was demonstrated that cAMP signaling rapidly potentiates the activity of TRPM6 by promoting its accumulation at the plasma membrane and by increasing its single channel conductance. Comparison of electrophysiological data between the phosphorylation-deficient S1252A and phosphomimetic S1252D mutants suggests that phosphorylation at this intracellular residue participates in the observed stimulation of channel activity.

Conclusions: These data support a physiologically relevant magnesiotropic role of cAMP signaling in the kidney by a direct stimulatory action of protein kinase A on the plasma membrane trafficking and function of TRPM6 ion channels in the distal convoluted tubule.

FR-PO931

Renal Handling of Magnesium in Individuals on Long Term Proton Pump Inhibitor Therapy Saubhik Sural. *Nephrology, Peerless Hospital& B K Roy Research Centre, Kolkata, West Bengal, India.*

Background: Proton Pump Inhibitors (PPI) are a group of very commonly used medication.Recently the US---FDA has issued warning regarding the risk of hypomagnesemia in patients receiving long term PPI therapy. The present study was conducted with the objective of evaluating the serum magnesium and renal handling of magnesium in long term PPI patients.

Methods: The study was designed as a case control study consisting of adult patients on long term PPI therapy (Omeprezole; Rabeprezole; Pantoprezole etc) for more than 1 year. Patients on PPI with diabetes, chronic kidney disease or on diuretics were excluded. Age and sex matched healthy controls not on any medication were included as controls. Serum Magnesium and Urinary Fractional Excretion of magnesium (FE---Mg) were measured using an automated clinical chemistry autoanalyser . Study was conducted for one year followed by statistical analysis of data with Graph-pad software.

Results: The mean age of the long term PPI group was 47.5years and 45.9years in the control population with no statistical difference between the two groups. Among study patients long term PPI users (n = 43) had a mean(SD) Mg level of 1.79 (0.17) mg/dL; and non--users (n = 43) 2.06 (0.30) mg/dL; p = 0.001. PPI use was associated with lower serum Mg levels (95% CI = 0.30 to 0.19). The FE---Mg of long term PPI users had a mean (SD) of 1.37(0.65) % and the control population 2.72(0.88); p = 0.001.Among the PPI group 9 patients (20%) had a serum Mg less than the lower limit of our population reference interval (1.7 mg/dl). None of them were clinically symptomatic for hypomagnesemia.The serum magnesium levels showed a negative correlation with the duration of PPI therapy(r= 0.502 ; p 0.01). The FE---Mg of the PPI group is significantly reduced suggesting increased renal conservation of magnesium in order to maintain near normal serum levels.

Conclusions: Compensatory renal conservation of Mg occours in long term PPI receiving patients. Thus if patients with impaired renal handling of Mg (diabetes; CKD or those on diuretics) receive long term PPI therapy they might possibly be at a greater risk of clinically significant hypomagnesemia.

FR-PO932

Magnesium Protects against Phosphate-Induced Kidney Injury in Mice with Uninephrectomy Yusuke Sakaguchi,[1] Takayuki Hamano,[2] Isao Matsui,[1] Akihiro Shimomura,[2] Yasuo Kusunoki,[1] Sayoko Yonemoto,[1] Daisuke Mori,[1] Hiromi Rakugi,[1] Yoshitaka Isaka.[1] *[1]Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; [2]Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.*

Background: We have recently reported that the risk of progression of CKD associated with high serum phosphate (P) was significantly attenuated in patients who had higher serum magnesium (Mg) levels (Kidney International in press), although the causality remains unclear. Here we studied whether Mg protects against kidney injury induced by P overload.

Methods: Eight-week-old C57BL6 mice underwent uninephrectomy and were divided into 4 groups: 1. high P (1.25 % P)-normal Mg (0.05% Mg) diet; 2. high P (1.25% P)-low Mg (0.005% Mg) diet; 3. low P (0.25% P)-normal Mg (0.05% Mg) diet; 4. low P (0.25% P)-low Mg (0.005% Mg) diet. Twenty-four-hour urine samples were collected for the measurement of daily urinary excretion of P. After 6 weeks of dietary intervention, mice were sacrificed and kidney tissues were harvested for histological analysis and mRNA quantification.

Results: Mice fed with the high P-low Mg diet showed severe tubular injury, interstitial fibrosis, and a marked accumulation of F4/80 positive cells in the interstitium; these changes were largely attenuated in mice in the high P-normal Mg diet group. Creatinine clearance in the high P-low Mg diet group was significantly lower than that in the high P-high Mg diet group (0.04±0.02 vs 0.27±0.14; $p<0.05$). Both TGF-βeta1 and TNF-alpha mRNA expression levels in the whole kidney were upregulated in the high P-low Mg diet group compared with those in the high P-normal Mg diet group. No histological evidence of kidney injury was found in both of the low P groups. Since urinary P excretion in the high P-low Mg diet group was equivalent (at 3 weeks) to or even lower (at 6 weeks) than that in the high P-normal Mg diet group, it is unlikely that the exacerbation of kidney injury in the high P-low Mg diet group was owing to an increased intestinal absorption of P.

Conclusions: Low Mg diet aggravates phosphate-induced kidney injury. Mg may be beneficial to reduce the phosphate toxicity to the kidney.

FR-PO933

Low Serum Magnesium Is Associated with an Increased Risk of Death from Coronary Heart Disease and Sudden Cardiac Death Brenda C.T Kieboom,[1,2] Robert Zietse,[2] Oscar Franco,[1] Albert Hofman,[1] Bruno H. Stricker,[1,2] Ewout J. Hoorn.[2] *[1]Epidemiology, Erasmus MC, Univ Medical Center Rotterdam, Rotterdam, Netherlands; [2]Internal Medicine, Erasmus MC, Univ Medical Center Rotterdam, Rotterdam, Netherlands.*

Background: Low serum magnesium has been associated with cardiovascular disease (CVD) mortality in population-based studies. However, results are conflicting and it remains unclear if this effect is mediated by an effect on atherosclerosis or heart rhythm.

Methods: We examined the relationship between serum magnesium and CVD mortality in 9,820 participants aged ≥ 45 years from the population-based Rotterdam Study. We used multivariable-adjusted Cox proportional hazard regression models and divided serum magnesium into quartiles, with the second and third quartile combined as reference group.

Results: During a median follow-up of 8.7 years, 780 participants died of CVD, including 431 deaths from coronary heart disease (CHD) and 217 sudden cardiac deaths (SCD). Low serum magnesium (£0.80 mmol/L) was associated with an increased CVD mortality risk (HR 1.25, 95% 1.05-1.50), including both death from CHD (HR 1.42, 95%CI 1.04-1.95) and SCD (HR 1.68, 95%CI 1.20-2.37). Low serum magnesium was associated with an increased QTc-interval, due to a strong effect on heart rate(RR interval -7.7 ms, 95%CI -14.7 to -0.7), but additional adjustment for heart rate did not change the association with SCD. Low serum magnesium was associated with increased intima media thickness (0.01 mm, 95%CI 0.004-0.020), and this explained part of the effect of magnesium on CHD mortality. Notable, high serum magnesium (≥ 0.89 mmol/L) was also associated with an increased risk of SCD (HR 1.50, 95%CI 1.05-2.16), but reduced risk of death from CHD (HR 0.64, 95%CI 0.43-0.95).

Conclusions: Low serum magnesium is associated with an increased risk of death from CHD, which is partly explained by an effect on atherosclerosis. Both low and high serum magnesium are associated with an increased risk of SCD. Although serum magnesium strongly affects heart rate, this did not explain the relationship between serum magnesium and SCD.

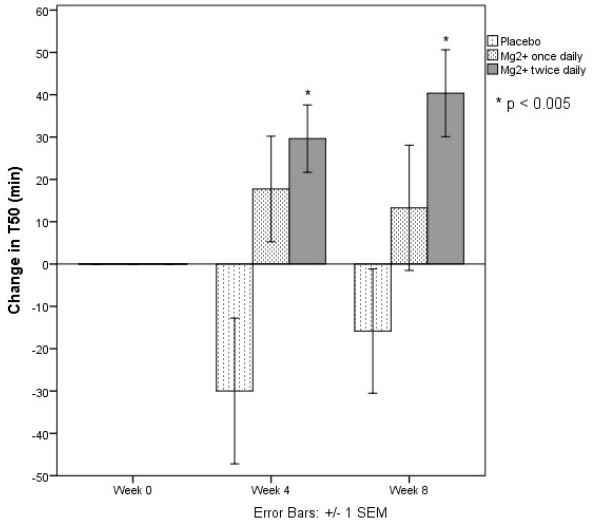
FR-PO934

Oral Magnesium Supplementation Improves Serum Calcification Propensity in Chronic Kidney Disease Stage 3-4 Iain B. Bressendorff,[1] Ditte Hansen,[2] Morten Schou,[3] Andreas Pasch,[4] Matthias Bachtler,[5] Lisbet Brandi.[1] *[1]Dept of Cardiology, Nephrology and Endocrinology, North Zealand Hospital, Hillerød, Denmark; [2]Dept of Medicine, Div of Nephrology, Roskilde Hospital, Roskilde, Denmark; [3]Dept of Cardiology, Herlev Hospital, Herlev, Denmark; [4]Dept of Clinical Chemistry, Univ Hospital Bern (Inselspital), Bern, Switzerland; [5]Dept of Clinical Research, Univ of Bern, Bern, Switzerland.*

Background: In previous experimental studies of chronic kidney disease (CKD) magnesium has been shown to improve vascular calcification. Serum calcification propensity measured using the T50 analysis has been shown to predict all-cause mortality among patients with chronic kidney disease (CKD) stage 3-4.

Methods: In a proof-of-concept randomized placebo-controlled double-blinded trial of placebo versus slow-release magnesium oxide at two different doses (360 mg once daily or 360 mg twice daily) for eight weeks in 34 subjects with CKD stage 3-4 and plasma magnesium <0.82 mmol/L, T50 was measured to examine whether magnesium supplementation affects serum calcification propensity.

Results: In subjects randomized to magnesium 360 mg twice daily (n = 11) plasma magnesium increased by 0.11 mmol/L (confidence interval; 0.05 - 0.17, p = 0.003) and T50 increased by 40 minutes (confidence interval; 18 - 63, p = 0.003) after eight weeks of treatment (Figure 1), while there were no changes in plasma phosphate, calcium or parathyroid hormone. There were no significant changes in T50 in the placebo (n = 12) or magnesium 360 mg once daily (n = 11) groups.



Conclusions: Oral magnesium oxide 360 mg twice daily improves serum calcification propensity in CKD stage 3-4 after eight weeks of treatment. Larger, long-term trials are needed to assess whether this translates into reductions in vascular calcification (e.g. coronary artery calcium score or pulse wave velocity) and cardiovascular endpoints.

FR-PO935

The Novel NaPi-IIb Inhibitor ASP3325 Does Not Mitigate Hyperphosphatemia in Chronic Kidney Disease Patients on Hemodialysis Tobias E. Larsson,[1] Chisato Kameoka,[2] Ikumi Nakajo,[2] Yuta Taniuchi,[2] Satoshi Yoshida,[2] Tadao Akizawa,[3] Ronald Alfons Smulders.[1] *[1]Astellas Pharma Europe BV, Leiden, Netherlands; [2]Astellas Pharma Inc., Tokyo, Japan; [3]Dept of Nephrology, Showa Univ School of Medicine, Tokyo, Japan.*

Background: The sodium-dependent phosphate co-transporter type 2b (NaPi-IIb) is considered an important mediator of active inorganic phosphate (Pi) transport and absorption in the small intestine. ASP3325 is a novel NaPi-IIb inhibitor effective for reducing the plasma Pi level in a rat model of adenine-induced renal failure and is currently in development for the treatment of hyperphosphatemia in chronic kidney disease (CKD).

Methods: Two phase 1 studies were conducted. Study 1 was a randomized double-blind placebo-controlled single and multiple ascending dose study in healthy subjects (HS). Dose levels ranged from 1-600 mg as a single dose and from 10-100 mg t.i.d. for 7 days. Study 2 was a multicenter open-label study in hyperphosphatemic CKD patients on hemodialysis. After an initial washout period of Pi binders, 100 mg ASP3325 was administered t.i.d. for 14 days.

Results: In Study 1, 124 HS were randomized either to ASP3325 (n=90) or placebo (n=34). ASP3325 was absorbed with a t_{max} ranging from 1.4 to 6.7 h; $t_{1/2}$ ranged from 15.5 to 22 h following single dosing under fasted conditions. AUC and C_{max} increased almost dose proportionally following dosing up to 100 mg t.i.d. under fed conditions. Urinary and fecal Pi excretion did not change following ASP3325 administration for 7 days. In Study 2, 9 patients received ASP3325 just before a meal while 10 patients received ASP3325 just after a meal. ASP3325 was generally well tolerated, however gastrointestinal related adverse events were reported in 21.1% of the patients. ASP3325 did not reduce the serum Pi level irrespective of timing of administration in relation to meals.

Conclusions: ASP3325 showed no effect on Pi parameters in both HS and CKD patients on hemodialysis. The role of orally administered NaPi-IIb inhibitors as treatment for hyperphosphatemia in humans remains uncertain.

Funding: Pharmaceutical Company Support - Astellas Pharma Inc.

FR-PO936

Novel NaPi-IIb Inhibitor ASP3325 Inhibits Phosphate Absorption in Intestine and Reduces Plasma Phosphorus Level in Rats with Renal Failure Keiichi Taniguchi, Kazuhiro Terai, Yoh Terada, Yuichi Tomura. *Drug Discovery Research, Astellas Pharma Inc., Tsukuba, Ibaraki, Japan.*

Background: The sodium-dependent phosphate co-transporter type 2b (NaPi-IIb) is considered to be an important mediator of intestinal inorganic phosphate (Pi) absorption and therefore recognized as a target molecule for treatment of hyperphosphatemia. We evaluated the pharmacological characteristics of ASP3325, a novel NaPi-IIb inhibitor being developed to treat hyperphosphatemia in chronic kidney disease (CKD).

Methods: The inhibition ratio of ^{33}P-Pi uptake during AP3325 (0.03-1000 nmol/L) treatment was measured in HEK293 cells stably expressing rat or human NaPi-IIb. To assess the contribution of NaPi-IIb to intestinal Pi absorption, ASP3325 and ^{32}P-Pi were orally administered in sequence, and then serum ^{32}P-Pi levels were measured. For normal rats, an ASP3325 containing-diet was provided for three days and the rate of Pi excretion in urine was measured on the final day. For rats with adenine-induced renal failure, an ASP3325 containing-diet was provided for two weeks after which plasma levels of phosphorus were measured.

Results: ASP3325 inhibited ^{33}P-Pi uptake with an IC_{50} value of 7.0 nmol/L in HEK293 cells expressing human NaPi-IIb and an IC_{50} value of 88 nmol/L in HEK293 cells expressing rat NaPi-IIb. In normal rats, oral administration of ASP3325 at 1 and 3 mg/kg significantly reduced the area under the concentration curve of serum ^{32}P-Pi levels from 0 to 30 min post ^{32}P-Pi administration. ASP3325 (0.001%-0.01%) reduced urinary Pi excretion dose-proportionally, and treated with 0.01% ASP3325 reduced excretion by 31.2% compared to vehicle (P<0.01). In rat with adenine-induced renal failure, ASP3325 (0.001%-0.01%) exhibited a dose-related reduction in plasma levels of phosphorus. Following two weeks of treatment, plasma level of phosphorus in the vehicle-treated group was 11.43 ± 0.66 mg/dL and in the 0.01% ASP3325-treated group was 6.61 ± 0.47 mg/dL (P<0.01).

Conclusions: ASP3325 inhibited NaPi-IIb-mediated Pi transport and decreased plasma levels of phosphorus in rats with renal failure as well as urinary Pi excretion in normal rats. ASP3325 might therefore be a novel candidate for the treatment of hyperphosphatemia in humans.

FR-PO937

Statin Therapy Reduces Phospate Levels in Dialysis Patients: Results from the Epidemiological Vitamin K Italian Study (VIKI Study) Maria Fusaro,[1] Sandro Giannini,[2] Marianna Noale,[1] Giovanni Tripepi,[4] Piergiorgio Messa,[3] Andrea Aghi,[2] Nicola Veronese,[2] Maurizio Gallieni,[5] Sabina Zambon.[2] *[1]CNR, Padua; [2]Univ of Padua; [3]Ospedale Maggiore Policlinico, Milan; [4]CNR, Reggio Calabria; [5]San Carlo Borromeo, Milan.*

Background: Statin therapy is the mainstay approach to reduce VC and prevent CV events in patients with dyslipidemia. The aim of this study was to investigate an association between statin therapy and plasma phosphate levels in patients on hemodialysis recruited in the VIKI Study.

Methods: The VIKI Study is a multicenter, cross-sectional study in 387 CKD patients on hemodialysis from 18hospital in Italy. We determined plasma levels of vitamin 25(OH) D, vitamin K, osteocalcin (bone-Gla-Protein or BGP), matrix-Gla-protein (MGP) and routine biochemistry. Assessment of VC was centralized (Witteman's method: by measuring the length of calcific deposits along the anterior and posterior wall of the aorta). Plasma phosphate levels were dichotomized according to the median value (>4.6 vs <4.6 mg/dl).

Results: 33% of the VIKI Study population (n=126) was on statin therapy. Patients on statin had significantly lower HDL cholesterol (mean±SD: 40.4±11.1 vs 43.3±13.4 mg/dl, p=0.0473) and higher plasma triglyceride levels (median: 164.0 vs 142.0 mg/dl, p=0.0041) than those not on statin. Plasma phosphate levels were significantly lower in patients on statin therapy (4.57±1.12 vs 4.86±1.33 mg/dl, p=0.0365). The analysis of the vitamin K components showed that patients on statin therapy had higher plasma MK7 levels (median: 1.16 vs 0.84ng/ml, p=0.0241), while concentrations of vitamin 25(OH)D were significantly reduced (median: 26.0 vs 30.7 nmol/l, p=0.0198). In a multivariate analysis adjusted for BMI, angina, LDL, BGP and antibiotics, statin therapy was significantly associated with lower plasma phosphate levels (OR 0.61, 95%CI 0.38-0.98, p=0.0411), while BMI (OR 1.06, 95%CI 1.01-1.12, p=0.0250) and serum BGP levels ≥ 182 mcg/L (OR 1.58, 95%CI 1.01-2.48, p=0.0472) were associated with higher phosphate concentrations.

Conclusions: To our knowledge this is the first evidence of an association between statins and reduced plasma phosphate levels in CKD patients.

FR-PO938

Epidemiology of Kidney Stone Disease in Icelandic Children 1985-2013 Solborg E. Ingvarsdottir,[1] Olafur S. Indridason,[2] Runolfur Palsson,[2,3] Vidar O. Edvardsson.[1,3] *[1]Children´s Medical Center, Landspitali – The National Univ Hospital of Iceland; [2]Div of Nephrology, Landspitali – The National Univ Hospital of Iceland; [3]Faculty of Medicine, Univ of Iceland, Reykjavik, NA, Iceland.*

Background: The aim of the study was to examine time trends in the incidence and prevalence of kidney stone disease in Icelandic children and adolescents over the past 3 decades.

Methods: Computerized databases of all major hospitals and medical imaging centers in Iceland covering the years 1985 to 2013, were searched for ICD, radiology and surgical procedure codes indicative of kidney stones for subjects <18 years of age. Incidence was calculated for the time periods 1985-1989, 1990-1994, 1995-1999, 2000-2004, 2005-2009 and 2010-2013, based on population information for Icelandic children in these years. Prevalence was calculated for the years 1999-2013.

Results: From 1985 to 2013, there were 186 incident patients, 110 (59%) of whom were female. Median (range) age at diagnosis was 15.0 (0.2-17.99) years. The annual incidence increased from a mean of 3.7/100,000 in the first 5 years to 11.0/100,000 in the years 1995-2004, but decreased thereafter and was 7.8/100,000 in 2010-2013. This trend was more pronounced in boys, for whom the incidence was 4.7/100,000 in the first time period, 11.0/100,000 during 2000-2004 and only 2.4/100,000 in 2010-2013. The incidence for girls increased from 2.7/100,000 in the first time period to 14.2/100,000 in 1995-1999 and has since then leveled off and was 13.6/100,000 in 2010-2013. The largest incidence rise was seen in girls aged 14-17 years, for whom it increased from 9.8/100,000 in 1985-1989 to 39.2/100,000 in 2010-2013. The mean annual prevalence of kidney stone disease in 1999-2013 was 44/100,000 for boys and 51/100,000 for girls.

Conclusions: The incidence rise observed and current incidence of kidney stones in Icelandic children is similar to that recently reported in the USA. A significant incidence increase was observed for both genders in the late 1980's and early 1990's but thereafter trended downwards in boys and remained stable in girls. These trends can not be adequately explained and warrant further study.

FR-PO939

Kidney Stone Recurrence in Icelandic Children Solborg E. Ingvarsdottir,[1] Olafur S. Indridason,[2] Runolfur Palsson,[2,3] Vidar O. Edvardsson.[1,3] *[1]Children´s Medical Center; [2]Div of Nephrology, Landspitali – The National Univ Hospital of Iceland; [3]Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland.*

Background: The 5-year recurrence rate of kidney stones in adults is in the range of 30-50%. No population-based data are available on the recurrence of childhood kidney stone disease. The purpose of this study was to examine the recurrence rate of stone disease in Icelandic children.

Methods: Patients were identified by searching computerized databases of all the major hospitals and the only freestanding radiology clinic in Iceland for diagnostic, radiology and surgical codes indicating kidney stones in 1985-2013. We subsequently examined medical records of patients with kidney stone disease for information on stone recurrence. A recurrent stone event was defined as radiologic signs of a new stone or a new episode of flank pain and hematuria. The Kaplan-Meier method was used to assess stone-free survival and the log-rank test to compare groups.

Results: We identified 186 children with stone disease during the study period. There were 76 boys with a median (range) age of 14.6 (0.2-17.9) years and 110 girls aged 15.4 (0.8-17.9) years. The follow-up time was 13.0 (0-36) years. A total of 67 children (37%) experienced a second stone event, at a median of 1.9 (0.9-18.9) years after the initial diagnosis. The recurrence rate was 26%, 35%, 41% and 46% after 5, 10, 15 and 20 years of follow-up, respectively. There was no significant difference in recurrence rate between boys and girls (p=0.24) and those aged under and over 13 years at diagnosis (p=0.56), but a significant difference between patients diagnosed in 1985-1994, 1995-2004 and 2005-2013 was observed, with a 5-year recurrence rate of 9%, 24% and 38%, respectively (p=0.002).

Conclusions: In our population-based pediatric study, the recurrence rate of kidney stones is similar to that reported in adults. Further, the rate of recurrence appears to be increasing as has recently been reported for the incidence of childhood stone disease. Increased recurrence rate may be related to improved diagnosis and documentation of stone events and/or environmental factors affecting urinary lithogenicity.

Clinical Stone Events in Patients Diagnosed with Asymptomatic Nephrolithiasis Berglind Eik Gudmundsdottir,[1] Rebekka Sigrún Lynch,[2] Runolfur Palsson,[2,3] Vidar O. Edvardsson,[1,2] Olafur S. Indridason.[3] *[1]Childrens Medical Center, Landspitali; [2]Faculty of Medicine, Univ of Iceland; [3]Div of Nephrology, Landspitali - The National Univ Hospital of Iceland, Reykjavik, Iceland.*

Background: More frequent use of high-resolution medical imaging in recent years has resulted in increased detection of asymptomatic kidney stones (KS). The purpose of this study was to investigate the frequency of clinical stone events in incident patients with asymptomatic KS.

Methods: We searched databases at all major hospitals and imaging centers in Iceland for radiologic and diagnostic codes indicative of KS in the years 2000-2008. We found 2550 incident cases, review of medical records identified 218 patients with no past history of nephrolithiasis or symptoms consistent with KS, who, therefore, were considered to have asymptomatic KS. The patients' records were then thoroughly reviewed for the development of a clinical stone event defined as abdominal/flank pain and hematuria associated with stone passage and/or a stone removal procedure. End of follow-up was between June 2014 and April 2015 or at patient's death. Event-free survival was examined by the Kaplan-Meier method.

Results: Of the 218 patients, 54.6% were men, the median (range) age was 65 (11-91) years. The diagnosis of KS was made by computed tomography in 156 (71.6%), ultrasound in 49 (22.5%) and by plain X-ray in 13 patients. The median follow-up time was 6.0 (0.0-14.5) and 6.7 (0.0-14.9) years for men and women, respectively. Twenty patients (9.2%) underwent a stone removal procedure shortly after diagnosis,. Additional 29 patients (13.3%) had a clinical stone event at a median of 2.8 (0.2-14.4) and 1.2 (0.1-9.3) years following diagnosis for men and women, respectively. When a procedure performed to remove an asymptomatic stone was considered a clinical event, a total of 49 patients experienced a clinical stone event, and the 5 and 10 year event-free survival was 80% (95% CI, 74-85) and 73% (95% CI, 65-80), respectively.

Conclusions: Approximately 10% of asymptomatic KS were considered clinically significant at diagnosis. In the remaining patients, a clinical stone event was unlikely to occur over a decade following diagnosis of asymptomatic stone disease.

FR-PO941

Population Attributable Fraction of Modifiable Risk Factors for Kidney Stones Pietro Manuel Ferraro,[1,2] Eric N. Taylor,[2] Giovanni Gambaro,[1] Gary C. Curhan.[2] *[1]Div of Nephrology, Catholic Univ of the Sacred Heart, Rome, Italy; [2]Channing Div of Network Medicine, Harvard Medical School, Boston.*

Background: Several dietary and lifestyle factors are associated with a higher risk of developing kidney stones. In this study, we estimated the population attributable fraction (PAF) of modifiable risk factors for kidney stones including body mass index (BMI), fluid intake, DASH-style diet, dietary calcium intake and intake of sugar-sweetened beverages (SSB).

Methods: We used data from three large ongoing cohorts, the Health Professionals Follow-up Study (41,937 men) and the Nurses' Health Studies (NHS) I (59,864 older women) and II (90,449 younger women). Information on risk factors and incident kidney stones was obtained from validated questionnaires. Cox proportional hazards regression models adjusted for age, race, geographic area, history of diabetes, history of hypertension and use of thiazides were used to estimate the association of each risk factor with development of kidney stones. PAF estimates were obtained by published equations.

Results: The study included 192,250 participants who contributed a total of 3,079,449 person-years of follow-up, during which 6,225 participants developed incident kidney stones. All the modifiable risk factors were independently associated with incident stones in each of the cohorts. The PAF ranged from 5.1% for higher SSB intake to 25.2% for lower fluid intake; the PAF for all the five risk factors combined was 58.1% in HPFS, 46.5% in NHS I and 44.2% in NHS II.

Conclusions: Modifiable risk factors, specifically BMI, low fluid intake, low DASH-style diet, low dietary calcium intake and high intake of SSB, account for about 50% of incident kidney stones in three large prospective cohorts, suggesting that a large proportion of kidney stones could be prevented. Assuming a causal relation, these estimates suggest that prevention measures aimed at reducing those factors could effectively reduce the burden of kidney stones in the general population.

FR-PO942

Assessment of Health-Related Quality of Life (HRQoL) in Rare Kidney Stone Formers (RKSF) Frank Modersitzki,[1] Alicia Meek,[2] David S. Goldfarb.[1] *[1]Medicine, New York Univ School of Medicine, New York, NY; [2]Medicine, Mayo Clinic, Rochester, MN.*

Background: Assessment of HRQoL in RKSF is important for following disease course and evaluating treatments. We previously showed that SF with cystinuria reported lower HRQoL than non-cystinuria SF. We now report on baseline characteristics of RKSF in the Rare Kidney Stone Consortium (RKSC) Registries, to be followed prospectively.

Methods: Patients were enrolled from 3 RKSC registries: primary hyperoxaluria (PH), cystinuria and Dent disease. In adults, HRQoL is measured using the SF-36v2 and in children, the SF-10. Participants choose between online assessment or paper-based questionnaire. Results are calculated as norm-based scores (NBS) based on US Standard Population = 50.

Results: 280 participants were enrolled; 200 adults, 80 children; 163 males, 118 females. Mean age was 34 years: for adults 44y and children 10y. 189 adults and 68 children were included in the baseline analysis: PH: 145, cystinuria: 71, Dent: 41. Domain scores for children are presented without cystinuria (n<10). For all participants, SF-36 NBS and summary scores for adults are below 50, except for the domain Physical Functioning (mean = 51.2). The lowest total domain score was in General Health with 45.8 +11.8. Adults had significantly different results in Role-Physical, Bodily Pain, Vitality, Social Functioning, Mental Health and Mental Component Score based on disorder. The lowest score was found in cystinuria for General Health (mean = 43.9). The summary scores for Physical Health (PHS) and Psychosocial (PSS) in children were 47.4 +14.2 and 51.80 +9.6 with

lowest summary scores for Dent disease 46.5 PHS and 48.8 PSS. The PSS was lower in Dent disease than PH and cystinuria (p = 0.03). PHS was significantly different in SF-10 specific age groups (p=0.05).

Conclusions: RKSF have worse HRQoL than US adults. HRQoL profiles in adults vary with genetic disorder. Cystinuria was associated with the worst domain and summary scores. Children RKSF have lower HRQoL PHS compared with adults, with the worst results in children with Dent Disease. We will correlate HRQoL with stones and disease course in the next 4 years.

FR-PO943

Supplemental Calcium Increases the Growth Rate of Renal Calculi in Stone Formers Christopher J. Loftus, Josephine Volovetz, Alexander Chaitoff, Jennifer C. Hu, Carol Swetlik, Joseph Roy Abraham, Manoj Monga, Juan C. Calle. *Glickman Urology and Nephrology Inst, Cleveland Clinic, Cleveland, OH.*

Background: Though dietary calcium is associated with a decreased risk of stone formation, post-menopausal women supplemented with calcium have an increased risk of urinary tract stones. Prior studies have examined the effect of supplemental calcium on the risk of passing symptomatic stones but its role in the pathogenesis of stone formation is not clear.

Methods: We retrospectively identified 6050 patients with a history of urolithiasis. Eligible patients had 2 unenhanced CT scans greater than 30 days but less than 2 years apart during the time of supplementation. For those on no supplementation, the most recent data were used. Of these, 426 patients met the criteria: 195 on calcium, 127 on vitamin D only, and 104 on none. Patients on calcium received 439mg/d± 2793IU vitamin D3/d or 5607IU D2/d and patients on vitamin D only received 3085 IU D3/d or 6296 IU D2/d. Stone burden was calculated as the sum of the maximum diameters of all stones on CT, and rate of stone growth was calculated by the change in consecutive stone burdens divided by the elapsed time between scans.

Results: Stone composition was similar among all groups: 65.5% calcium oxalate, 20.0% calcium phosphate, and 11.8% uric acid. Stone formation rate in mm/year±standard deviation was 7.8±20.8 for calcium group, 3.3±11.4 for vitamin D, and 4.49±13.8 for none. Those supplemented with calcium had a higher rate of stone formation than those supplemented with vitamin D alone, p=0.0105. Supplement group was statistically significant when controlling for serum PTH and calcium on multiple logistic regression. BMI, gender, age and dose of calcium were not significantly associated with stone formation rate while dose of vitamin D3 had an inverse association, p=0.0490.

Conclusions: Supplementation with calcium was associated with a significant increase in stone growth rate in stone formers. Vitamin D supplementation showed no added risk and may potentially have a protective effect. Though the pathophysiology is unclear, these data suggest patients at risk of stone formation should be cautious of supplementation use.

FR-PO944

Effects of Calcium and Vitamin D Supplementation on Known Stone Formers Christopher J. Loftus, Josephine Volovetz, Alexander Chaitoff, Carol Swetlik, Jennifer C. Hu, Joseph Roy Abraham, Manoj Monga, Juan C. Calle. *Glickman Urology and Nephrology Inst, Cleveland Clinic, Cleveland, OH.*

Background: While high dietary calcium has protective effects against kidney stone formation, the effect of supplementation with calcium and vitamin D on the risk of kidney stone formation remains unclear. Post-menopausal women supplemented with calcium have an increased risk of urinary tract stones; however, there is conflicting evidence for the effects of supplementation on urinary excretion of calcium.

Methods: We identified 6050 patients with a history of urolithiasis by CT scan, 2061 of which had 24-hour urine collections before and after starting supplementation. For patients on no supplement, the most recent data were used. A total of 1,486 patients were supplemented with calcium, 417 with vitamin D only, and 158 with no supplementation. Patients on calcium received an average of 460mg/d± 2726IU vitamin D3/d or 5678IU D2/d and patients on vitamin D only received 3005IU D3/d or 6307IU D2/d.

Results: Stone composition did not differ among groups: 70.0% calcium oxalate, 16.6% calcium phosphate, and 10.8% uric acid stones. There was a significant decrease in urinary calcium excretion in patients supplemented with calcium (p=0.021) and vitamin D (p=0.011) and significant decreases in urinary oxalate in those supplemented with calcium (p<0.0001) and vitamin D (p<0.0001). No differences were seen in the amount of change between supplemented groups for any urinary excretion values.

	Calcium	Vitamin D	None	p-value difference between groups
serum Calcium (mg/dL)	-0.005	-0.005	0.01	0.86
serum Vitamin D (ng/mL)	3.7	7.6	-1.2	<0.0001*
serum PTH (pg/mL)	8.1	-0.43	-5.3	0.024*
urinary Calcium (mg/d)	-5.1	-8.9	5.3	0.19
urinary Oxalate (mg/d)	-4.2	-3.1	-2.0	0.38

The table shows changes from baseline. Among all groups, higher serum calcium was associated with higher urinary calcium excretion (p<0.0001); higher serum calcium (p=0.0007)and vitamin D (p=0.026) were associated with and lower oxalate excretion.

Conclusions: Both calcium and vitamin D supplementation decreased urinary calcium excretion. High serum calcium but not vitamin D was associated with higher urinary calcium excretion in both men and women.

FR-PO945

Tolvaptan Therapy Effectively Decreases Urinary Calcium Oxalate, Calcium Phosphate, and Uric Acid Supersaturations in Stone Formers Wisit Cheungpasitporn,[1] Stephen B. Erickson,[1] Andrew D. Rule,[1] Felicity T. Enders,[2] John C. Lieske.[1] *[1]Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Dept of Health Sciences Research, Mayo Clinic, Rochester, MN.*

Background: Drinking large amounts of fluids is universally recommended for urinary stone prevention but can be difficult to do for many stone formers. Tolvaptan, a V2 receptor antagonist, blocks water reabsorption in the collecting duct. This in turn should increase serum osmolality and stimulate thirst. The net effect should be lower supersaturation of stone forming salts, but this has not been proven.

Methods: This double blind, randomized, placebo-controlled, crossover study was conducted in 21 adult calcium urinary stone formers, stratified as majority calcium oxalate (CaOx, n=10) or calcium phosphate (CaP, n=11). Patients were randomized to receive tolvaptan 45 mg/day or placebo for week 1, followed by washout week 2, and then crossover to drug or placebo for week 3. The 24 hr urine volume and chemistries were assessed at the end of week 1 and week 3.

Results: Tolvaptan versus placebo decreased urinary osmolality (204±96 vs 529±213 mOsm/kg, P<0.001) and increased urinary volume (4.8±2.9 vs 1.8±0.9 L, P<0.001). However, the majority of urinary salt excretion rates (mg/24 hrs) including sodium and calcium did not significantly change. Thus, urinary CaOx SS (-0.01±1.14 vs 0.95±0.87, P<0.001) and CaP SS (-1.66±1.17 vs -0.13±1.02, P<0.001) both decreased. Urinary Uric Acid (UA) SS also fell (-2.05±4.05 vs -5.24±3.12, P=0.03). The tolvaptan treatment effect on urinary supersaturation did not different between CaOx and CaP stone types (P>0.05 for all interactions). Serum sodium increased slightly while on tolvaptan (142±3 vs 141±2 mEq/L, P=0.01).

Conclusions: Use of tolvaptan increased urinary volume but did not appreciably change daily excretion of urinary constituents. The net effect was thus a fall in CaOx, CaP and UA SS. This study highlights the dramatic benefit increased free water ingestion alone can have on urinary supersaturation. Use of tolvaptan or other V2 receptor antagonists could be a useful strategy for selected stone formers not responsive to intensive dietary and/or behavioral counseling.

FR-PO946

Effect of Increasing Doses of Cystine Binding Thiol Drugs (CBTDs) on Cystine Capacity (CysCap) in Patients with Cystinuria Deepa A. Malieckal,[1,2] Felicity T. Enders,[3] Frank Modersitzki,[1] John R. Asplin,[4] David S. Goldfarb.[1,2] *[1]Internal Medicine, Div of Nephrology, New York Univ School of Medicine, New York, NY; [2]Internal Medicine, Div of Nephrology, NY Harbor VA Healthcare System, New York, NY; [3]Health Sciences Research, Div of Biomedical Statistics & Informatics, Mayo Clinic, Rochester, MN; [4]Litholink Corp, Chicago, IL.*

Background: We have proposed that CysCap is a superior measure of lithogenicity when using CBTDs in cystinuria. CBTDs significantly increase urinary CysCap compared to no CBTD. We studied the effect of increasing doses of CBTDs on CysCap in patients with cystinuria.

Methods: 6 patients on CBTDs took 4 different doses of their usual CBTD over 4 weeks: 0, 1, 2, and 3gm for 7 days in random order. On day 6 and 7 they reproduced a self-selected diet and on day 7 of each of the 4 weeks, they did a 24h urine collection to measure CysCap. CysCap values were compared for each of the 4 weeks. 3 patients took tiopronin and 3 patients took d-penicillamine. Alkali doses were unchanged.

Results: All patients had more positive CysCap when switched from 0 to 1gm of CBTDs (p<0.03). There was no further change in CysCap with doses >1gm. Generalized least squares regression demonstrated that only the dose of CBTDs was a predictor of CysCap (p<0.03). Although reproducibility of diet and collections was not attained (based on 24h urine sodium and creatinine), urine sodium and volume were not predictors of CysCap. Those patients with the most negative CysCap values had the greatest positive effect when taking 1gm compared with 0gm CBTD.

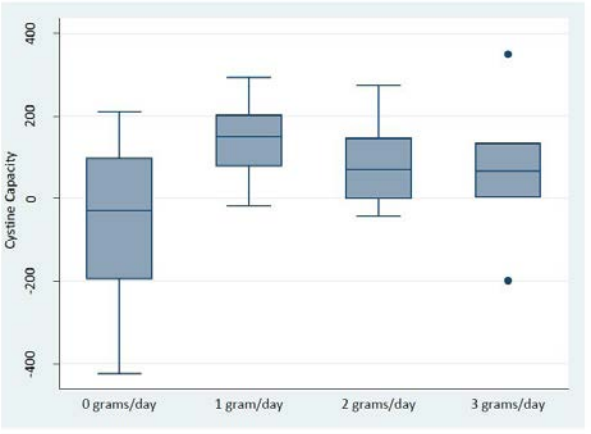

Figure 1. Effect of CBTD dose on CysCap. Length of box: IQR; whiskers: range; line in box: median; ●: outliers.

Conclusions: Prescribing doses of CBTDs greater than 1 gm did not improve lithogenicity significantly. Higher doses may not have clinical benefit. Prescribing the minimum effective dose based on CysCap can potentially decrease the adverse effects often associated with CBTDs.

FR-PO947

Claudin-14 Gene Polymorphisms May Regulate Urine Calcium Excretion

Teresa Arcidiacono, Marco Simonini, Lorenza Macrina, Paolo Manunta, Donatella Spotti, Giuseppe Vezzoli. *Nephrology and Dialysis Unit, San Raffaele Scientific Inst, Milan, Italy.*

Background: Claudins are a family of proteins that form paracellular calcium channels in tight-junctions and may thus regulate tubular permeability to divalent cations. Claudin-14 is expressed in the ascending limb of Henlke's loop and inhibits calcium reabsorption. A previous GWA showed that two polymorphisms (SNPs) of *CLDN14* (rs219778 e rs219781) were associated with kidney stones and calcium excretion in an Iceland population. The present study is aimed to explore the effect of CLDN14 SNPs on calcium excretion.

Methods: We ha performed a retrospective study on 380 hypertensive patients never treated with antihypertensive drugs. These patients underwent a saline load test (i.v. infusion with NaCl 0.9% 2 litres in 2 hours) to evaluate sodium sensitivity. Kidney stones in their clinical history was ascertained by interview. Calcium was measured in 24-h urine and in every 2 hours during the saline load test. Patient genotypes of the CLDN14 gene were obtained from the GWA data.

Results: Kidney stones were reported by 9.3% of patients. No association was found between CLDN14 SNPs and stones. As previously observed, rs219778 was associated with 24-hour calcium excretion that was also associated with many SNPs of the CLDN14 gene. The most significant association occurred with rs219755 (GG 5.62±3.10, GA 4.86±2.49, AA 3.11±1.82 mmol/24h ; p=0.00014). The association with calcium excretion was also observed when calcium excretion after saline load was considered (considering rs219755: GG 0.75±0.51, GA 0.72±0.46, AA 0.44±0.27 mmol/2h; p=0.02).

Conclusions: CLDN14 genotype is associated with calcium excretion. This association is observred even after saline load test, a well known stimulus to urinary calcium excretion. Minor alleles of these SNPs could cause a reduction of calcium excretion and could be protective against kidney stones and hypercalciuria. The lack of association among stones and CLDN14 SNPs could be due to the method used to identify stone formers.

FR-PO948

Independent Effect of Blood Glucose Level on Urinary Citrate and pH

Majuran Perinpam,[1] Erin Bakshis Ware,[3,4] Jennifer Smith,[3] Stephen T. Turner,[1] Sharon R. Kardia,[3] John C. Lieske.[1,2] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Laboratory Medicine, Mayo Clinic, Rochester, MN; [3]Dept of Epidemiology, School of Public Health, Univ of Michigan, Ann Arbor, MI; [4]Inst for Social Research, Univ of Michigan, Ann Arbor, MI.*

Background: Urinary citrate is an important kidney stone inhibitor and its excretion is influenced by systemic acid base status and diet. However, the effects of demographics and other factors on urinary citrate excretion are not well defined, including the independent influence of blood glucose.

Methods: Twenty-four hour urine samples were collected from non-Hispanic white sibships in Rochester, MN. Height, weight, blood pressure, blood glucose, serum creatinine and cystatin C were measured. Diet was assessed using the Viocare food frequency questionnaire. The effects of blood glucose, demographics and diet on urinary citrate excretion, urine pH and net gastrointestinal (GI) alkali absorption were evaluated in bivariate and multivariable models, plus interaction models that included age, sex, and weight.

Results: Samples were available from 709 individuals (mean age 66±9 years). In general urine citrate and urine pH correlated positively with higher net alkali absorption (p<0.0001). Urine pH was higher in women for any given net alkali absorption value, but not after adjustment for covariates. In multivariable models urinary pH decreased with higher serum creatinine, blood glucose, dietary protein and increased with dietary potassium. Meanwhile, in multivariable models urinary citrate increased with age, weight, $eGFR_{Cys}$, blood glucose and decreased with loop diuretic and thiazide use. Association of urinary citrate and age was influenced by blood glucose (p=0.01).

Conclusions: In our study urinary citrate and pH correlated positively with net GI alkali absorption. Blood glucose had independent effects on urine pH and urinary citrate. This study provides the first evidence that blood glucose could influence stone risk independent of urinary pH and uric acid crystallization. These observations could provide new insights into the association of obesity and urinary stone disease.

FR-PO949

Renal Oxalate Secretion Reduces Risk of Systemic Oxalosis in Primary Hyperoxaluria

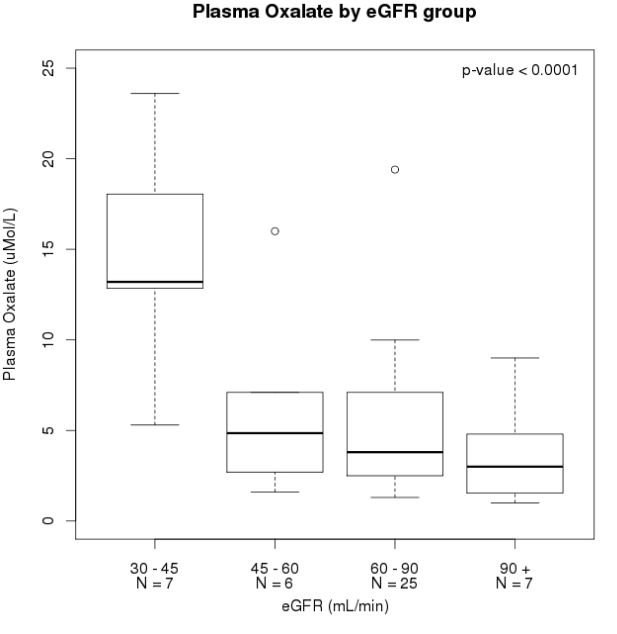
Brady A. Brabec, Kristin C. Mara, Felicity T. Enders, Ramila A. Mehta, John C. Lieske, Dawn S. Milliner. *Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Primary Hyperoxaluria (PH) is a rare genetic disease causing high hepatic production of oxalate. Renal excretion of oxalate keeps plasma oxalate (Pox) controlled but leads to stones and often ESRD. Systemic oxalosis occurs when GFR is reduced and Pox rises above the supersaturation threshold (approximately 45 mmol/L). Renal handling of oxalate in relation to GFR is poorly understood.

Methods: PH patients ≥ 12 years without ESRD were identified from the Rare Kidney Stone Consortium registry. We used the most recent simultaneous Pox, serum creatinine and 24 hour urine oxalate (Uox). Net oxalate secretion (Sox) equals Uox-GFR×Pox. Proximal tubular oxalate (PTox) is Uox corrected for creatinine and estimated proximal tubule water absorption. eGFR is by CKD-EPI (adults) or modified Schwarz (adolescents). We grouped patients by CKD stage and balanced eGFR groups. Analysis was by Fischer exact test and ANOVA.

Results: 45 patients were identified (33 PH-1; 5 PH-2; 7 PH-3). Median age was 23.2 (IQR: 16.7, 32.9) and eGFR was 66.1 mL/min/BSA (54.4, 80.8). Pox, Sox and Uox rose sharply when eGFR fell below 45 mL/min. Similar results were seen in eGFR groups. PTox and Pox increased proportionally (p<0.001).

CKD stage (n)	CKD 1 (7)	CKD 2 (25)	CKD 3a (6)	CKD 3b (7)	p value
PH type 1	6	16	5	6	0.505
Uox mmol/day (SD)	1.01 (0.52)	1.40 (0.72)	1.38 (0.58)	2.60 (0.98)	0.0008
Pox µmol/L (SD)	3.67 (2.82)	5.12 (4.09)	6.18 (5.20)	14.84 (5.85)	<0.0001
PTox µmol/L (SD)	0.21 (0.15)	0.47 (0.29)	0.55 (0.22)	1.26 (5.85)	<0.0001
Sox mmol/day (SD)	0.36 (0.62)	0.88 (0.72)	0.92 (0.32)	1.74 (0.95)	0.007



Conclusions: Compensation for high oxalate production in PH is maintained through CKD stage 3a. Higher PTox in CKD stage 3b may accelerate proximal tubular CaOx crystallization. Risk for systemic oxalosis is low until at least CKD stage 4.

FR-PO950

Effect of Antibiotic Treatment on *Oxalobacter formigenes* Colonization
Lama Nazzal, Sukhleen Bedi, Fritz Francois, David S. Goldfarb, Guillermo I. Perez perez, Martin J. Blaser. *Medicine, New York Univ, New York, NY.*

Background: Kidney stones are a disease of worldwide prevalence with significant public health implications. About 60–80% of stones are composed of calcium oxalate (CaOx). Hyperoxaluria is a major risk factor. *Oxalobacter formigenes (OF)*, a member of the human colonic microbiota, plays a major role in net colonic oxalate absorption and secretion. We now report *OF* colonization rates in a young healthy population, the stability of colonization, and the effects of antibiotic treatment on *OF* colonization.

Methods: We followed 64 healthy subjects tested for *Helicobacter pylori* (HP), who were treated with antibiotics (Amoxicillin and clarithromycin for 2 weeks) for HP eradication. Using species-specific PCR, we tested for *OF* colonization at baseline and at follow-up.

Results: Of the 64 subjects (M/F: 24/40; mean age 25.0 + 5.5y) tested for *OF*, 25 (39%) were positive at baseline. Of 7 *OF*+ subjects at baseline, subject to HP elimination, 6 became *OF*-negative at 6 wks, only 2 reverted to positive at week 24, and 4 patients remained negative at follow up (Mean 21.0 + 6wks). Of 16 untreated positive people, 12 (75%) remained positive at follow up (Mean 18.8 +7.7w), but of 26 untreated negative subjects, only 6 (23%) were positive at follow up (mean 19.7+ 6.6wks), significantly fewer than the untreated positives (p=0.001 by Fisher exact test).

Conclusions: We conclude that *OF* status remains stable over a follow-up period of several months, with antibiotics suppressing colonization in the majority of people in the short term. The differential long-term effect of antibiotics on *OF* colonization and its effect on urinary oxalate excretion, will be important to evaluate.

FR-PO951

Identification of Calcium-Oxalate Binding Proteins in Human Urine That Prevent Crystal Adhesion in an *In Vitro* Model of Kidney Stone Formation
Scott R. Manson, Joel F. Koenig, Qiusha Guo, Katelynn H. Moore, Paul F. Austin. *Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.*

Background: There are limited therapeutic options for the treatment of stone disease and about 50% of patients experience at least one recurrence. Existing treatment protocols focus on altering urine concentrations, which presents challenges due to the idiopathic nature of many stones and the variety of underlying factors. In this study, we examine the hypothesis that there are naturally occurring urinary proteins capable of binding calcium oxalate crystals, promoting their clearance, and preventing stone formation. Elucidating these interactions may provide novel therapies.

Methods: Calcium oxalate monohydrate (COM) crystals and fluorescently-labeled derivatives (COM-FITC) were synthesized *in vitro*. Stone formation was modeled *in vitro* by assessing the adhesion of COM-FITC crystals to confluent monolayers of inner medullary collecting duct (IMCD) epithelial cells. Affinity chromatography was used to isolate COM-binding proteins from human urine.

Results: COM and COM-FITC crystals synthesized *in vitro* exhibited the typical prismoidal morphology of urinary crystals. Incubation of IMCD cells with COM-FITC crystals resulted in rapid binding to the cell surface with high affinity. The addition of urinary proteins purified from human urine inhibited COM-FITC binding by 76.2%. Furthermore, urinary proteins inhibited the growth of COM crystals in free solution by 63.7%. In using affinity chromatography to isolate COM-binding proteins, we found that this technique was highly specific as only 17.2% of urinary proteins exhibited binding activity. The bound fraction was eluted, purified by electrophoresis, and four prominent proteins were identified (97 kD, 69 kD, 56 kD, 45 kD).

Conclusions: This study demonstrates that urinary proteins bind to COM crystals and inhibit their adhesion to the renal epithelium. Further characterization of these proteins may facilitate the design of peptide-based therapies that prevent crystal adhesion and stone formation as well as the development of diagnostic biomarkers that stratify patients and guide treatment decisions in at-risk populations.

Hydroxyapatite Induces Tolerance in Primary Human Monocytes Exposed to Calcium Oxalate Crystals
Benjamin Canales,[1] Paul R. Dominguez Gutierrez,[1] Sergei Kusmartsev,[1] Johannes Vieweg,[1] Saeed R. Khan.[2] *[1]Urology, Univ of Florida, Gainesville, FL; [2]Pathology, Immunology, and Laboratory Medicine, Univ of Florida, Gainesville, FL.*

Background: Although most crystal deposits within tissue produce inflammation, renal interstitial hydroxyapatite deposits do not, accumulating as Randall's plaque. To further explore this lack of response, we investigated the effect of oxalate, hydroxyapatite, and combination of both on time dependent, immunological responses in human THP-1 (monocyte) cells, the precursors to tissue macrophages.

Methods: Using 1 ug/ml LPS and untreated as positive and negative controls, THP-1 cells were exposed to varying concentrations of soluble potassium oxalate (KOx) or CaOx and HA crystals (10, 100, and 1000 ug/m). In addition, a group of primary human monocytes cells were pre-treated with 100 ug/ml of HA or CaOx followed by secondary treatment with 100 ug/ml HA, 100 ug/ml CaOx, and 1 ug/ml LPS. THP cells were collected at 2, 4, and 8 hours after various treatments, and RNA was analyzed by quantitative real time PCR.

Results: THP-1 cells responded strongly to CaOx in a dose dependent manner producing TNFa, IL-1b, IL-8, and IL-10 with little to no response to KOx and HA. Pre-exposure of human monocytes to HA had little effect on cytokine response to subsequent CaOx and LPS exposure; however, pre-exposure to CaOx followed by HA negated all further cytokine production.

Conclusions: In our human monocyte model, the order of CaOx and HA exposure affects monocytic response. HA neither stimulates cytokine production nor inhibits cytokine production when pre-treating monocytes prior to CaOx exposure. Pre-treated CaOx monocytes, however, had decreased cytokine and chemokine expression when secondarily treated with HA. This tolerance mechanism may partially explain the lack of papillary inflammation in the pathogenesis of Randall's plaque.

FR-PO953

A Low Sodium Diet Inhibits Stone Formation in Genetic Hypercalciuric Stone-Forming Rats
Kevin K. Frick,[1] Nancy S. Krieger,[1] John R. Asplin,[2] Ignacio Granja,[2] Min Ho Kim,[1] Felix M. Ramos,[1] David A. Bushinsky.[1] *[1]School of Medicine & Dentistry, Univ of Rochester, Rochester, NY; [2]Litholink Corporation, Laboratory Corporation of America Holdings, Chicago, IL.*

Background: Increasing dietary (D) sodium (Na) intake results in greater urine (u) calcium (Ca) excretion, leading to the recommendation that D Na be restricted in hypercalciuric stone formers to decrease stone recurrence. However, there is no direct clinical evidence that reduction in D Na intake alone will reduce recurrent stone formation.

Methods: To determine if D Na restriction reduces kidney stone formation, we utilized 101st generation genetic hypercalciuric stone-forming (GHS) rats fed either a low (LNa, 0.05%) or normal (NNa, 0.4%) Na D for 18 wks. Urine was collected at 6 wk intervals; a mean was determined for each analyte and then an overall 18 wk mean calculated. Radiographic analysis for stone formation was done at 18 wks.

Results: As anticipated, LNa decreased mean uNa (NNa=2.48±0.03 mmol/24h; LNa=0.39±0.02, p<0.001) and uCl (NNa=2.65±0.13 mmol/24h; LNa=1.19±0.06, p<0.001). Overall mean uCa was lower with LNa than NNa (NNa=17.3±0.5 mg/24h; LNa=15.2±0.5, p<0.01) as was u phosphate (P) (NNa=16.5±0.6 mg/24h; LNa=13.8±0.4, p<0.001). Urine oxalate (Ox), pH, NH_4^+, citrate and volume did not differ with diet Na. There were no significant differences in u supersaturation with respect to CaP or CaOx. Serum Ca was slightly increased with LNa (NNa=10.9±0.1 mg/dL; LNa=11.4±0.1, p<0.01) though there were no differences in serum P, PTH or FGF23. Radiographic analysis of kidneys demonstrated a significant decrease in calcification with LNa (calcification scores with a range of 0-3: NNa=1.14±0.15; LNa=0.32±0.12, p<0.001).

Conclusions: Thus a low Na diet reduced uCa and stone formation in GHS rats even though urine supersaturation was not altered. These data, in a genetic model of hypercalciuria and stone formation, lend support to the use of dietary Na restriction to prevent recurrent Ca nephrolithiasis.

Ethylene Glycol Induced Hyperoxaluria in Rats: A Transcriptional Study
Sunil Joshi,[1] Wei Wang,[1] Ammon B. Peck,[2] Saeed R. Khan.[1] *[1]Pathology, Immunology, and Laboratory Medicine, College of Medicine, Univ of Florida, Gainesville, FL; [2]Infectious Diseases and Pathology, College of Veterinary Medicine, Univ of Florida, Gainesville, FL.*

Background: Hyperoxaluria, if remains undiagnosed, can cause renal injury and inflammation leading to a number of diseases including advanced stages of renal failure. In order to look into the different pathways and molecular mechanisms involved in the kidneys of hyperoxaluric rats, we performed genome wide analysis of differentially expressed genes in the kidneys of rats fed ethylene glycol (EG).

Methods: Male rats were divided into two groups. Rats in one group were fed normal diet and the other group diet supplemented with 1.25% EG. Urinary assays were done at different time intervals and after 14 and 28 days rats were euthanized, kidneys explanted and total RNA extracted for micro array analysis using Agilent 8 x 60K single color arrays. Data was analyzed using bio-conductor Limma (Linear models for micro array analysis) package using R. Gene ontology (GO) and KEGG pathway analyses was also performed. Immunohistochemical (IHC) and Eosin and Hematoxylin (E &H) staining was also done for highly significant genes.

Results: All rats became hyperoxaluric from day 7 and had crystal deposition at different time intervals. Urinary LDH, sodium and creatinine were significantly different in the EG group as compared to the control. There was significant expression of different genes encoding for macromolecular modulators such as osteopontin (OPN), monocyte chemoattractant protein-1 (MCP-1), lipocalin 2 (Lcn-2), fibronectin (Fn-1), clusterin (CLU) and kidney injury molecule-1 (KIM-1) along with nicotine amide dinucleotide phosphate (NADPH) oxidase-4 (NOX-4) and glutathione peroxidase (Gpx-2). Gene analysis showed 17 and 33 differentially expressed pathways for day 14 and day 28 respectively.

Conclusions: Results highlight that the EG treated rats showed heavy deposition of crystals and there were 15 pathways that were common between day 14 and day 28 giving a deep insight into the molecular mechanisms and pathways activated in hyperoxaluric rats.

Sulfate and Thiosulfate Competitively Inhibit Oxalate Transport via a *Drosophila* Prestin (dPrestin, dSlc26a6)-Dependent Mechanism

Greg M. Landry,[1,2,3] Taku Hirata,[1,3] Jacob B. Anderson,[1] Christopher Joseph roel Gallo,[1] Michael F. Romero.[1,2,3] *[1]Physiology and Biomedical Engineering, Mayo Clinic College of Medicine, Rochester, MN; [2]Nephrology and Hypertension, Mayo Clinic College of Medicine, Rochester, MN; [3]O'Brien Urology Research Center, Mayo Clinic College of Medicine, Rochester, MN.*

Background: Nephrolithiasis affects approximately 12% of men and 6% of women in industrialized countries with the majority of stones being composed of calcium oxalate (CaOx).

Methods: Using Drosophila melanogaster as a robust and translatable model of CaOx nephrolithiasis, we studied the effects of sulfate and thiosulfate on oxalate transport, and subsequent CaOx crystal formation, as a proof of principle in providing a nidus to identify new therapeutic interventions.

Results: Results indicate that dprestin transports thiosulfate with a much higher affinity than sulfate (dprestin sulfate K_m = 8.65 ± 3.87 mM compared to dprestin thiosulfate K_m = 0.23 ± 0.03 mM). Additionally, both sulfate (48 h) and thiosulfate (24 and 48 h) were effective at decreasing Malpighian tubule CaOx crystallization with the opposite results observed at 48 h in Malpighian tubules where dPrestin was not expressed indicating a role for principle cell-specific dPrestin in luminal oxalate transport.

Conclusions: Given the higher affinity of thiosulfate for dprestin when compared to those which are reported for oxalate (dprestin average K_m for oxalate= 0.87 ± 0.16 mM and for thiosulfate = 0.22 ± 0.03 mM), we have concluded that the ability of thiosulfate to act as a competitive inhibitor of oxalate at the transporter level, specifically dPrestin, may explain the decrease in CaOx crystallization seen in the presence of thiosulfate, but not sulfate. Overall, our findings predict that thiosulfate or oxalate-mimics may be effective as therapeutic competitive inhibitors of CaOx crystallization.

Complement Receptor 3 Mediates Renal Protection in Experimental C3 Glomerulopathy

Thomas D. Barbour, Guang Sheng Ling, Marieta Milkova Ruseva, Liliane Fossati-Jimack, H. Terence Cook, Marina Botto, Matthew C. Pickering. *Centre for Complement and Inflammation Research, Imperial College, London, United Kingdom.*

Background: C3 glomerulopathy (C3G) is a progressive form of glomerulonephritis (GN) that is frequently associated with abnormalities in regulation of the alternative pathway (AP) of complement. Mice with deficiency of factor H (*Cfh-/-*), a negative AP regulator, are an established experimental model of C3G in which abundant complement C3 accumulates along the glomerular basement membrane.

Methods: We examined the spontaneous renal phenotype in *Cfh-/-* mice with and without accompanying deficiency of complement receptor 3 (CR3), the main receptor for iC3b. We performed accelerated serum nephrotoxic nephritis (ANTN) in CR3-deficient mice to assess the role of CR3 in glomerular injury outside the setting of FH deficiency. The effect of iC3b ligation of CR3 on macrophages and other leukocytes during inflammation was assessed *in vitro*.

Results: In 8-month old *Cfh-/-* mice, accompanying CR3 deficiency was associated with significantly increased albuminuria, glomerular hypercellularity and macrophage influx, and mortality. Bone marrow (BM) transplantation experiments in *Cfh-/-* recipients indicated that the protective effect of CR3 was dependent on BM-derived cells. ANTN produced severe, crescentic nephritis in CR3-deficient mice (but not wild-type mice). *In vitro* ligation of CR3 using iC3b-coated particles down-regulated the proinflammatory cytokine response of both murine and human macrophages to lipopolysaccharide stimulation *in vitro*. These cytokine-modulating effects were cell-type specific, an observation that may reconcile some of the conflicting reports concerning the immune role of CR3 in the literature.

Conclusions: Deficiency of CR3 unexpectedly enhanced the severity of both experimental C3G and immune complex GN. Our findings suggest that pharmacological potentiation of the CR3-iC3b interaction could be therapeutically useful in patients with chronic GN.

FR-PO957

Two Autoimmune Forms of C3-Glomerulopathy Are Defined by Complement Convertases Deregulating Autoantibodies

Christine Skerka,[1] Fei Zhao,[1] Giuseppe Remuzzi,[2] Rossella Piras,[2] Peter F. Zipfel.[1,3] *[1]Dept of Infection Biology, Leibniz Inst for Natural Product Research and Infection Biology, Jena, Germany; [2]Laboratory of Immunology and Genetics of Transplantation and Rare Diseases, IRCCS- Istituto di Ricerche Farmacologiche, 24020- Ranica (Bergamo), Italy; [3]Friedrich Schiller Univ, Jena, Germany.*

Background: In C3Glomerulopathy (C3G) defective complement activation on level of the C3 convertase is caused by mutations in genes coding for complement components or regulators as well as by autoantibodies. C3 nephritic factor (C3NeF) has been reported in 50-80% of C3G patients. Notably also autoantibodies to C3b and Factor B were identified in C3G patients, which do not score in the standard C3NeF assay. Here we compare how the new C3 convertase reacting antibodies and also C3Nef affect complement regulation on the level of the C3- and the C5 convertases.

Methods: The autoantibodies were isolated from the serum of C3G patients (n=34), assayed for binding to the C3 convertase by ELISA and further characterized by using a number of functional complement assays.

Results: Among the 34 C3G patients, 19 patients were identified with autoantibodies which bind to the C3 convertase, but lack C3NeF. 15 patients were identified C3NeF positive. According to the binding to the C3 convertase, high titer (HT) and low titer (LT) antibodies were identified among isolated autoantibodies from all 34 C3G patients. HT as well as LT antibodies strongly activated the C5 convertase and enhanced C5a generation. Interestingly all antibodies bound to the C3 convertase, but only HT and not LT antibodies enhanced C3 convertase activity. The HT but not the LT antibodies increased C3 convertase assembly, stabilized the convertase and increased C3a generation.

Conclusions: Two classes, HT and LT, of complement C3 convertase binding autoantibodies were identified in C3NeF- positive and negative C3G patients. These antibodies deregulate complement by two different mechanisms: HT antibodies activate complement on the C3- and C5 convertase levels, while LT antibodies activate only on C5 convertase level. We speculate that these functional different autoimmune forms explain responder and non-responder types to therapeutic C5 inhibitors.

Autoimmune C3 Glomerulopathy: Can Complement Inhibiting Drugs Reduce Complement Activation by C3 Convertase Autoantibodies?

Friederike Sophie Schulze,[1] Fei Zhao,[1] Giuseppe Remuzzi,[2] Marina Noris,[2] Christine Skerka,[1] Peter F. Zipfel.[1,3] *[1]Hans Knöll Inst, Jena; [2]Mario Negri Inst for Pharmacological Research, Bergamo; [3]Friedrich Schiller Univ, Jena.*

Background: C3 glomerulopathy is a severe kidney disorder that is caused by deregulation of the alternative complement pathway. Identified causes include genetic mutations, copy number variations in the CFHR gene cluster as well as autoimmune factors. Some patients but not all respond to therapy with the complement inhibitor Eculizumab. Recently a new class of C3 convertase antibodies was identified in C3G patients who lack classical C3Nephritic factor (C3Nef). We aim at characterising how these new autoantibodies cause complement deregulation and how complement inhibitors affect the action of these autoantibodies.

Methods: IgGs were purified from patients with C3 convertase antibodies lacking C3Nef (n=19) and also from C3Nef+ patients (n= 15). These purified IgGs were tested for their impact on complement activity and the effect of soluble CR1 (sCR1) and Eculizumab was examined by ELISA, Western blot and complement activation assays.

Results: C3 convertase antibodies from patients lacking C3Nef deregulated complement. Some antibodies stabilized the C3 convertase and all activated the terminal complement pathway. C3Nefs activated complement in a related manner. In probes with C3 convertase antibodies sCR1 did inhibit excessive complement activity. Also Eculizumab prevented antibody mediated complement activation. Both inhibitors blocked C3Nef-mediated complement deregulation in a related manner. For some probes from either C3NeF+ or C3NeF- patients a higher dose of sCR1 was necessary to affect C3 convertase activity.

Conclusions: A subgroup of C3G patients present with C3 convertase-binding antibodies but lack C3Nef. Some C3 convertase antibodies deregulate the C3 convertase and all stabilize the C5 convertase. The complement inhibitors sCR1 and Eculizumab reduced complement activity. Patients with antibodies causing only excessive C5 convertase activity may benefit from Eculizumab, whereas patients with excessive C3 convertase may require additional C3 convertase inhibition.

Respiratory Syncytial Virus May Exacerbate Kidney Damage in IgA Nephropathy Through C3a/C3aR and C5a/C5aR Signaling Amplifying the Effects of Th17 Cells

Xiaozhao Li,[1] Xinyue Hu,[2] Ting Meng,[1] Juntao Feng,[2] Qiaoling Zhou.[1] *[1]Dept of Nephrology, Xiangya Hospital of Central South Univ, Changsha, Hunan, China; [2]Dept of Clinical Laboratory, Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: The exacerbation of IgA nephropathy (IgAN) is related to respiratory tract infection with respiratory syncytial virus (RSV), but the mechanism is unknown. In this study we investigated the role of complement activation productsC3a/C5a and their receptor C3aR/C5aR in response to the effect of T helper 17 (Th17) cells in the pathogenesis of IgAN associated with RSV.

Methods: IgA nephropathy was induced in BALB/c mice with lipopolysaccharide, carbon tetrachloride and bovine serum albumin. Then the mice were sensitized with C3aRA(C3aR antagonist) and C5aRA(C5aRA antagonist) respectively and infected with respiratory syncytial virus (RSV) in sequence. Urine Albumin-Creatinine ratio and sediments were measured. The pathological changes in kidney and lung tissues were observed under microscopy. C3aR and C5aR proteins in kidney tissue were examined by immunohischemical staining. Th17 cells and regulatory T cells (Tregs) in kidneys were tested by flow cytometry. C3a,C5a, IL-17A, IL-6 and IL-21,IL 22 in the kidneys were detected by ELISA.

Results: The IgAN mice had albuminuria and microscopic hematuria, renal mesangial proliferation, IgA deposition, high electron dense deposition in glomerular mesangial region, decreased frequency of Tregs, increased frequency of Th17 and Th17-Treg ratio. Furthermore, C3a, C5a, C3aR, C5aR and Th17-related cytokines IL-17A, IL-6 and IL-21 were all increased in the kidneys of IgAN mice. Compared with IgAN mice, the manifestations in RSV-IgAN mice were more severe, but alleviated in C3aRA-treated groups and C5aRA-treated groups respectively.

Conclusions: RSV infections may exacerbate kidney damage in IgAN through C3a/C3aR and C5a/C5aR signaling amplifying the Effects of Th17 Cells. The first two authors contributed equally to this work.

FR-PO960

Functional Glomerular Decay Accelerating Factor Induction by Heme: Role of HO-1 Maria Detsika,[1] Giouli Makri,[1] Vasileios Atsaves,[1] Pu Duann,[2] Elias A. Lianos.[1,2] *[1]Medicine, Univ of Athens, Greece; [2]Medicine, Rutgers Biomedical and Health Sciences, NJ.*

Background: In hemolytic disorders and glomerular injury associated with hematuria intraglomerular free heme increases and may activate the alternative complement (C)-pathway. Rat glomeruli express decay accelerating factor DAF in glomerular epithelial cells (GEC). We assessed whether heme upregulates glomerular DAF to minimize C activation and explored underlying mechanisms.

Methods: *hmox1*$^{+/-}$ and *hmox1*$^{-/-}$ rats were generated by Zinc Finger Nuclease (ZNF)-mediated HO-1 gene disruption and rats with GEC targeted HO-1 overexpression (GEC^{HO-1}) by Sleeping Beauty Transposon mediated transgenesis using a nephrin promoter. Wild type (WT) or *hmox1*$^{+/-}$, *hmox1*$^{-/-}$ or GEC^{HO-1} glomeruli were treated for 18 h with heme (hemin, FePP) or non-iron porphyrins with opposite effects on HO activity: 1) HO inducers, Cobalt (CoPP) and the non-metal protoporphyrin IX (PPIX) and 2) HO inhibitors: Zinc (ZnPP), Tin (SnPP) protoporphyrins, Tin (SnMP) and Chromium (CrMP) mesoporphyrins. C3b deposition in glomeruli was triggered by exposure to 10% rat serum. DAF, HO-1 and C3b levels were assessed by western blotting or Real-time PCR. HO enzyme activity was measured by standard methods.

Results: Constitutive DAF (mRNA and protein) decreased in both *hmox1*$^{+/-}$ and *hmox1*$^{-/-}$ and increased in GEC^{HO-1} glomeruli. Heme, at concentrations encountered in hemolytic disorders (50-400 μM), increased DAF expression in WT glomeruli. This effect was attenuated in both *hmox1*$^{+/-}$ and *hmox1*$^{-/-}$ and augmented in GEC^{HO-1} glomeruli. Heme-mediated DAF induction in *hmox1*$^{-/-}$ glomeruli persisted despite complete HO-1 absence. Of the non-Fe porphyrins, CoPP, ZnPP, and PPIX increased DAF and HO-1. SnPP induced DAF but not HO-1. SnMP and CrMP had no effect on either protein. Hemin or SnPP-mediated DAF induction reduced C3b deposition. This was reversed by PI-PLC which removed membrane bound DAF.

Conclusions: HO-1 regulates constitutive DAF expression and heme-mediated DAF induction. The latter is independent of metal moiety and HO enzyme activity, requires the porphyrin ring and may also occur via a HO-1 independent mechanism. DAF induction by heme is functional and attenuates C-activation.

Complement Activation Impairs Endothelial Cell Migration – Possible Role in TMA Pathogenesis Magdalena Riedl, Daniel Schlam, Fred G. Pluthero, Walter H. Kahr, Christoph Licht. *Cell Biology Program, The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Cell migration is a key requirement in multiple physiological scenarios including angiogenesis and endothelial cell repair. Thrombotic microangiopathy (TMA) is characterized by endothelial cell (EC) activation and injury, in atypical hemolytic uremic syndrome caused by complement activation on ECs. We hypothesized that EC injury in aHUS was – at least in part – caused by complement-mediated inhibition of cell migration.

Methods: To test this hypothesis blood outgrowth ECs were exposed to complement by blocking EC surface regulators (CD46, CD55, CD59) and incubating ECs with 50% normal human serum (NHS; complement active). Heat inactivated serum (HIS; complement inactive), C5-depleted serum (terminal pathway inactive) and media served as controls.

Results: Wound healing assay in fluidic conditions (wound infliction via trypsin/EDTA) showed within 1.5h a wound area decrease to 62.5±4% when perfused with media. Subsequent (1.5h) HIS perfusion allowed for further wound area reduction to 38±6%, similar to C5-depleted serum (46±5%). In contrast, exposure to complement (NHS) inhibited further wound closure (wound area 63±7%, $p<0.05$). The proliferation rate (% BrdU positive cells after 2 h) was similar between controls and complement-exposed ECs (20±2 vs. 21±3%), and no apoptosis or necrosis was detected within a 30min - 4h observation period (Annexin V, live dead aqua dye). However, we demonstrated an instantaneous but transient cell membrane perforation (via C5b-9, FM1-43X dye) with subsequent Ca^{2+} influx (Fura-2). Consequences of this sublytic C5b-9 deposition caused immediate and sustained (2h) cyto-skeletal (live cell imaging of F-actin, Rho-GTPases), cell-cell contact (decreased VE-Cadherin expression, decreased transendothelial resistance) and cell motility abnormalities (live cell imaging) in complement-exposed ECs, all leading to defective cell migration.

Conclusions: Our data suggest that sublytic EC complement exposure results in impaired cell migration leading to EC injury and defective EC repair – findings extending our current concept of TMA pathogenesis.

FR-PO962

Uncommon Features in Antigen Binding Sites of Human Anti-Glomerular Basement Membrane Autoantibodies Mary H. Foster, Elizabeth Sarah Buckley, Amy G. Clark. *Medicine, Duke Univ Medical Center and Durham VAMC, Durham, NC.*

Background: Detection of pathogenic anti-alpha3(IV)NC1 collagen autoAb in the serum or kidneys is required for diagnosis of anti-GBM nephritis and Goodpasture Syndrome, yet little is known about the origin and structure of human autoAb in these diseases. The heterogeneity of serum Ig, lack of ready access to key tissues in patients, and inability to reproduce complex immunological microenvironments in vitro present formidable barriers. Humanized models provide a novel platform to circumvent these obstacles.

Methods: We generated Hu-HSC mice by injection of human CD34+ hematopoietic stem cells into immunodeficient NOD-scid-gamma hosts. Mice with an established human immune system (mean blood chimerism 15.0±15.9% at 3 mons post-injection) were immunized twice with alpha3(IV)NC1 collagen prior to tissue harvest. Human B cells were EBV transformed using CpG oligos and kinase inhibitors, screened for antigen binding, electrofused with a human heterohybridoma, and subcloned. The mAb sequences were determined using PCR of cDNA with published primer panels and analyzed using IMGT/V-QUEST.

Results: Sequence analysis of 6 non-clonally related human anti-alpha3(IV)NC1 mAb reveals skewed gene use and unusual motifs in the critical HCDR3 that is predominantly responsible for antigen binding. 4 of 6 (67%) human mAb are encoded by an IGH J6 allele, the extended sequence of which enriches for aromatic tyrosine residues in HCDR3. The HCDR3 are exceptionally long, with mean length 26.4 amino acids (a.a.) compared to average human HCDR3 of 15.2 a.a., and include hydrophobic motifs, an autoimmune signature uncommon in Ig repertoires of healthy individuals and of unimmunized Hu-HSC mice. Similar motifs were observed in murine anti-alpha3(IV)NC1 mAb, despite substantial species differences in Ig gene loci and a.a. composition.

Conclusions: Our results suggest that binding of alpha3(IV)NC1 collagen by human anti-GBM autoAb requires unusual structural motifs that can access recessed hydrophobic epitopes and that are normally excluded from the healthy human immune repertoire. Similar motifs in man and mouse suggest origins by convergent selection.

FR-PO963

Antigenicity Alteration of Deglycosylated Myeloperoxidase Juntao Yu,[1] Zhao Cui,[2] Minghui Zhao.[2] *[1]Academy for Advanced Interdisciplinary Studies, Peking Univ, Beijing, China; [2]Renal Div, Peking Univ First Hospital, Beijing, China.*

Background: Myeloperoxidase (MPO) is a kind of enzyme located in the azurophilic granules of neutrophils, which is the most common target antigen of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) in Chinese patients. Native MPO possesses five N-glycans at positions 323, 355, 381, 483 and 729. The alteration of MPO antigenicity after deglycosylation of these glycans is not elucidated.

Methods: We prepared deglycosylated MPOs via glycosidases based on commercial human-derived intact MPO, and then detected the antigenicity of deglycosylated MPOs in 40 patients with anti-glomerular basement membrane (GBM) disease without MPO-ANCAs.

Results: We found antibodies against deglycosylated MPOs existed in patients with anti-GBM disease. 12/40 (30%) patients were positive for MPO treated with PNGase F (naked MPO without hydrocarbon side-chain). 12 (30%) patients were positive for MPO treated with Endo H (MPO with one GluNAc only). Antibody against the intact native MPO was not detectable in all these patients. Furthermore, clinical analysis presented that the levels of antibodies against deglycosylated MPOs were positively associated with renal dysfunction. The plasma levels of antibodies against naked MPO without glycan were positively correlated with the concentrations of serum creatinine (P=0.006, R^2=0.178). The plasma levels of antibodies against MPO with one GluNac only were also positively correlated with the concentrations of serum creatinine (P=0.002, R^2=0.234).

Conclusions: The existence of patients' antibodies towards deglycosylated MPO first discovered the new epitope exposure of MPO after the loss of hydrocarbon side-chain, explicating the possible reasons for antigenicity alteration, and then prompting some clinical significance of these antibodies.

FR-PO964

Autoantibodies to a Cryptic Myeloperoxidase-Specific Immunodominant Epitope Correlate with Disease Activity in Patients with MPO-ANCA Vasculitis Jacob J. Hess, Meghan E. Free, Olivier Lardinois, Donna O. Bunch, Caroline J. Poulton, JulieAnne G. McGregor, J. Charles Jennette, Ronald J. Falk, William Franklin Pendergraft. *UNC Kidney Center, Univ of North Carolina, Chapel Hill, NC.*

Background: ANCA vasculitis is commonly characterized by polyclonal autoantibody reactivity to one of two autoantigens, proteinase 3 (PR3) and/or myeloperoxidase (MPO). ANCA positivity has been observed in patients with active and quiescent disease. A subset of MPO-ANCA in many patients recognize a peptide sequence referred to as KIV. This peptide is buried within MPO suggesting that this epitope may be exposed by mechanisms that are not yet understood. We assessed human anti-KIV reactivity longitudinally in a large cohort of patients with MPO-ANCA vasculitis to better understand the temporal association of the autoantibody response.

Methods: Serum, plasma, and extensive clinical data from patients with ANCA vasculitis were prospectively collected every 3 months. A highly sensitive and specific indirect ELISA using KIV peptide was developed to longitudinally screen patient samples for reactivity over their disease course. To minimize non-specific antibody signal, reactivity to a scrambled peptide of the same amino acid composition was also measured. A positive signal was defined as two standard deviations above the healthy control mean (HC n=85).

Results: Of 67 patients with MPO-ANCA vasculitis, 28 were positive for human anti-KIV autoantibodies at least once during their disease course spanning an average follow-up of 3.3 years. The majority of these patients displayed positivity during initial stages of disease that receded over time while other patients exhibited recrudescence of reactivity. Further structural analysis of autoantibody binding to native MPO confirmed this peptide to be a cryptic epitope.

Conclusions: These findings suggest that conformational changes in MPO that expose this cryptic epitope may be important in the pathogenesis of MPO-ANCA vasculitis and may provide insight into the etiology of this disease. Furthermore, this assay could help to more clearly define temporal disease activity.

An Anti-GBM Autoantibody Gene Contributes Risk to Distinct Anti-Collagen Responses Amy G. Clark, Inge M. Worni-Schudel, Mary H. Foster. *Medicine, Duke Univ Medical Center and Durham VAMC, Durham, NC.*

Background: The mechanism by which anti-GBM nephritis is initiated and regulated remains an enigma. Recent studies indicate that anti-GBM patients' serum IgG react with multiple collagen chains and with atypical alpha3(IV)NC1 epitopes, and that diverse murine anti-collagen autoAb are genetically linked. We examined these relationships in a novel autoAb transgenic (Ig Tg) model expressing an IGKV3 gene used at low frequency in adult mice but enriched in anti-GBM Ig and arthritogenic anti-collagen II IgG.

Methods: Mice expressing an IGKV3-encoded Ig kappa light chain Tg were bred with B6 kappaKO mice, such that all kappa is Tg-derived, and use of lambda chains reflects regulation by editing. Purified B cells or whole splenocytes were cultured +/- Toll-like receptor ligands (TLR4L or TLR7/TLR9L). Quantitation of Tg autoAb binding to alpha3(IV)NC1 collagen or collagen II was performed by ELISA (expressed as OD405 on Ag-coated minus diluent-coated wells, n=6-10 mice/group, mean ± SD).

Results: Tg receptor expression was detected on 65±14% of B cells, with in vivo regulation suggested by low serum kappa levels (µg/ml, 27±28 vs 1029±611 for nonTg kappa+ controls, $p<0.01$). AutoAb were not detected in supernatants from unstimulated cells (mean OD 0.003±0.006), but were detected after TLRL stimulation. AutoAb specificity varied according to TLRL and with: (1) B cell surface lambda (editor) expression: anti-collagen II Ig, OD 0.271±0.122 vs 0.037±0.056, $p<0.001$, for high-lambda-expressing mouse Tg lines L16/L21 (mean lambda+ 47.5±12.4% of cells) vs low-lambda line L24 (mean 25±11.7% lambda+); and, (2) Presence of non-B cells: anti-alpha3(IV)NC1 collagen Ig, OD 0.124±0.104 vs 0.038±0.033, $p<0.001$, for whole splenocyte cultures vs purified B cells (all data shown for TLR7/TLR9L).

Conclusions: This new model confirms a role for IGKV3 genes in determining different anti-collagen specificities, including reactivity to GBM. This and data not shown suggest that the different specificities are not crossreactive, arise from non-overlapping cell populations, and are regulated in vivo by mechanisms that can be overcome by TLRL or hematopoietic cell interactions.

Autoantibodies Target Multiple Epitopes in THSD7A in Primary Membranous Nephropathy Hong Ma, David J. Salant, Laurence H. Beck. *Medicine, Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: Thrombospondin type-1 domain-containing 7A (THSD7A) is a large type 1 transmembrane glycoprotein expressed by the podocyte. It serves as the *in situ* antigen in a subset of primary membranous nephropathy patients. Its extracellular domain consists of a regularly repeating structure composed of thrombospondin type-1 and F-spondin repeats, as well as a highly basic region. We sought to investigate the location(s) of the humoral epitopes targeted by anti-THSD7A antibodies in membranous nephropathy.

Methods: N- and C-terminal truncation mutants of THSD7A, as well as constructs comprising single or multiple adjacent domains, were expressed in HEK293T cells. Reactivity with human autoantibodies was assessed by western blot, dot blot, and immunoprecipitation.

Results: Patient sera displayed varying degrees of reactivity to these recombinant constructs, with most sera reacting with 2 or more distinct domains in the more C-terminal, extracellular region of the molecule. A subset of patients also recognized an additional epitope in the N-terminal portion of the molecule. Reactivity with the larger constructs, such as THSD7A serially truncated from the N- or C-termini, was stronger than that against constructs composed of 1 to 4 adjacent domains, and could be detected by western blot, dot blot, and immunoprecipitation. Reactivity with single domains or several multiple adjacent domains was most prominent when detected by immunoprecipitation, and less consistently detected by western blot, which may suggest the presence of conformation-sensitive epitopes within the molecule.

Conclusions: As in PLA2R-associated membranous nephropathy, the humoral response to the target antigen THSD7A involves multiple epitopes within the molecule. Reactivity with autoantibody appears to depend on the conformation of an extended THSD7A extracellular region. Further analysis of additional anti-THSD7A positive sera will help to better define the dominant epitopes within the molecule, understand the pathogenesis of this autoimmune disease, and identify potential targets for novel therapeutics.

Intramolecular Epitope Spreading in Phospholipase A_2 Receptor in IMN Quansheng Zhu,[1] Hong Tang,[1] Phat H. Duong,[1] Meryl A. Waldman.[2] *[1]Medicine, UCLA, Los Angeles, CA; [2]NIDDK/Kidney Disease Section, National Insts of Health, Bethesda, MD.*

Background: Idiopathic membranous nephropathy (IMN) is an organ specific autoimmune disease. The major antigen responsible for developing IMN in patients has been identified to be the phospholipase A_2 receptor (PLA_2R) expressed in the glomerular visceral epithelial cells. Clinical studies demonstrated that over 70% of IMN patients possess circulating autoantibodies that target PLA_2R triggering immune complexes formation in situ and deposition in the glomerular subepithelial spaces. The immunodominant epitope in PLA_2R was recently located to the extreme N-terminus of the receptor encompassing the CysR-FnII-CTLD1 region. In the rat model of MN, epitope spreading was detected in the antigenic protein, megalin that is correlated with the disease progresses. Whether epitope spreading occurs in human IMN and its relationship to disease progresses is unclear.

Methods: Serum samples from biopsy-proven IMN patients were collected and screened for anti-PLA_2R antibodies using Western-blot and epitope-specific ELISA assays. The reaction of autoantibody and PLA_2R epitope protein was further analyzed using immunoprecipitation and immunoblocking assays.

Results: Western-blot analysis using patient sera against full-length PLA_2R or the dominant epitope region indicated that, 3 of the 12 serum samples that were positive with anti-PLA_2R autoantibodies failed to recognize the dominant epitope protein. Further test of these 3 samples against a series of truncated PLA_2R extracellular domains on Western-blot demonstrated that the autoantibodies bind strongly to the CysR-FnII-CTLD1-3 region of PLA_2R. Interestingly, serial analysis of sera from a patient with worsening proteinuria showed that, the autoantibodies first recognized the CysR-FnII-CTLD1-3 region and then spread to the CysR-FnII-CTLD1 region, suggesting epitope spreading is associated with the disease progresses.

Conclusions: Our results demonstrate for the first time that intramolecular epitope spreading occurs in PLA_2R in IMN. This finding supports the important role of the dominant epitope in IMN pathogenesis and disease progresses.

FR-PO968

Demonstration of a High Titer Low Affinity Anti-PLA_2R Autoantibody in an IMN Patient En Route to End-Stage Renal Disease Michael Shye,[1] Theresa L. Nilson,[1] Ritu Vahi,[1] Miguel Fernando Palma Diaz,[2] P.C. Pham,[1] Phat H. Duong,[1] Liyo Kao,[1] Douglas Yao,[1] Ira Kurtz,[1] Quansheng Zhu.[1] *[1]Medicine, Univ of California, Los Angeles, Los Angeles, CA; [2]Pathology, Univ of California, Los Angeles, Los Angeles, CA.*

Background: Clinical studies have established that over 70% of patients with idiopathic membranous nephropathy (IMN) possess high levels of circulating autoimmune antibodies targeting phospholipase A_2 receptor (PLA_2R) in the glomerular visceral epithelial cells (podocyte). Binding of autoantibodies to PLA_2R triggers immune complex formation in situ that impairs podocyte biology resulting in foot process effacement and subsequently proteinuria in patients. In this study, we monitored the fluctuation of autoantibody level in a patient progressing to the end-stage renal disease (ESRD) under the supportive treatments.

Methods: Serum samples from an IMN patient progressing to ESRD under supportive treatments over a period of 6 month were collected (5 clinical visits) and tested for the level of anti-PLA_2R antibodies using western-blot, indirect immunofluorescence staining and epitope-specific ELISA assay. The reaction of autoantibodies toward the dominant epitope region of PLA_2R was further analyzed using immunoprecipitation under the non-denaturing and denaturing conditions.

Results: A sharp decline of autoantibody reactivity toward PLA_2R in sera from the last two visits was detected on Western-blot as the patient approaching ESRD. In contrast, an epitope-specific ELISA assay indicated that the autoantibodies were remained at high levels in these two serum samples, and this observation is further confirmed by by the immunofluorescence staining analysis. Test of epitope-antibody reaction under the non-denaturing and denaturing conditions revealed that, the properties of the autoantibodies in the last two visits differ significantly from that in the first three visits, which have low affinity toward PLA_2R and only bind to the non-denatured form of the epitope.

Conclusions: Our results demonstrate that a high titer low affinity anti-PLA_2R autoantibody presents in an IMN patient at the late stages of IMN approaching ESRD under the supportive treatments. This autoantibody has altered reactivity toward PLA_2R that only binds to the non-denatured immunodominant epitope of the receptor.

FR-PO969

Immune Complex Binding to Renal Endothelial Cells Induces TRAIL and Promotes Apoptosis Scott E. Wenderfer, Adisak Suwanichkul. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Background: Circulating immune complexes (IC) deposit in the glomeruli of the kidney in many autoimmune diseases, leading to proliferative glomerulonephritis. IC binding can promote proliferation or induce apoptosis in human macrovascular EnCs.

Tumor necrosis family (TNF) superfamily members regulate proliferation and apoptosis, and both ligands and receptors are produced by glomerular endothelial cells (EnC). Tnfsf10/TRAIL is up-regulated in the kidneys of patients with IC disease.

Methods: Renal EnCs were cultured from C57BL/6 mice and primary human glomerular EnCs were obtained commercially. Cells were treated with heat aggregated IgG or peroxidase anti-peroxidase IC. Quantitative RT-PCR was used to measure mRNA levels of TNF superfamily members. A cellular ELISA was used to assess TRAIL protein expression on EnC surfaces. Apoptosis was assessed using XTT and H2AX phosphorylation, and caspase 3 activity assays, as well as TUNEL staining. *In vitro* findings were validated in a non-inflammatory murine model of acute IC kidney injury.

Results: TRAIL mRNA expression is up-regulated by renal endothelial cells *in vitro* in the presence of IC binding and *in vivo*. Membrane TRAIL expression on EnCs also increases after treatment with IC in a dose dependent manner. Receptors for TRAIL, DR5, DR6 are also expressed by EnCs at RNA and protein level. Using XTT cell proliferation assays, there is a modest decrease in EnC metabolism or proliferation after treatment with IC. Caspase 3 activity and DNA double strand breaks were both increased in cultured EnCs after treatment with IC in a dose dependent manner. Results were similar for both murine and human glomerular EnCs.

Conclusions: Results suggest that IC binding to glomerular EnCs *in vitro* is pro-apoptotic. Several TNF superfamily members known to promote apoptosis and their receptors are also up-regulated on EnCs treated with IC. Targeting TRAIL binding to DR5 and its downstream signaling pathways may reduce EnC activation or injury in IC kidney diseases.

Paired Immunoglobulin-Like Type2 Receptor α (PILRα) Negatively Regulates Immune Complex-Mediated Glomerulonephritis

Yutaka Sugiyama, Naotake Tsuboi, Yutaka Kamimura, Shoichi Maruyama, Seiichi Matsuo. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: PILRα expressed mainly on macrophages, dendritic cells and granulocytes, has been described for its regulatory functions for leukocyte β2 integrin activation in acute inflammation including LPS-induced endotoxin shock model. Here, we investigated roles of PILRα in immune complex (IC)-mediated glomerular inflammation.

Methods: IC-mediated glomerulonephritis was induced by intravenous administration of nephrotoxic serum (NTS) after pre-immunization with rabbit IgG in C57BL/6 (WT) and PILRα$^{-/-}$ mice. Functional analysis for renal injury was performed by urine albumin and serum creatinine (sCr) concentrations at day 7, 14 and 21. Diseased kidneys from both mouse strains were harvested for histology, renal leukocyte infiltrates by flow cytometry and renal cytokine profiles by ELISA after induction of NTS glomerulonephritis. In vitro, $\alpha_{m\beta2}$ integrin-dependent neutrophil adhesion on IC was evaluated in both mouse strains.

Results: BUN and sCr concentrations were significantly elevated in PILRα$^{-/-}$ mice compare to wild type mice at day 14 and day 21 and those were highly associated with deteriorated proteinuria. In histological analysis, glomerular damages, corroborated with both glomerular PAS deposits and glomerular crescent formation, were more severe in PILRα$^{-/-}$ mice at day 21 ($p<0.05$). Moreover, glomerular neutrophil accumulation was remarkably observed in PILRα$^{-/-}$ mice compare to WT mice at day 21. In addition, total infiltration of Ly6G^{high} neutrophils, F4/80^{+} macrophages and CD3^{+}CD4^{+} T cells in whole kidneys were increased in PILRα$^{-/-}$ mice than WT mice at day 14 and day 21. Renal proinflammatory cytokine profiles for IL-1β and IL-6 on day 21 also demonstrated severe renal inflammation in PILRα$^{-/-}$ mice. In vitro, PILRα deficient neutrophils showed enhanced adhesion and spreading on IC compared to WT.

Conclusions: PILRα$^{-/-}$ deficiency resulted in deteriorated renal damage in mouse IC-mediated glomerulonephritis compare to WT mice, indicating that PILRα negatively regulates IC-mediated leukocyte recruitment by inhibition of $\alpha_{m\beta2}$ integrin activation.

FR-PO971

Role of Interferon Regulatory Factor 5 and Toll-Like Receptor 7 in Immune-Complex Glomerulonephritis

Abraham Cohen-Bucay, Barry K. Horne, Yao Xie, Prachi Shukla, Ian R. Rifkin, Ramon G. Bonegio. *Renal Section, Boston Univ Medical Center, Boston, MA.*

Background: Immune-complex glomerulonephritis (ICGN) is a common cause of glomerular inflammation characterized by the *in situ* formation of immune complexes and activation of the complement cascade. Interferon regulatory factory 5 (IRF5) is a transcription factor acting downstream of toll-like receptors 7 (TLR7) to trigger an inflammatory response. Recent genetic studies have associated systemic lupus erythematosus and other autoimmune syndromes with gain-of-function polymorphisms in the IRF5 gene. We therefore hypothesized that deletion of IRF5 or TLR7 would ameliorate ICGN.

Methods: We induced nephrotoxic nephritis using an endotoxin-free IgG1 fraction of sheep nephrotoxic serum (NTS) in FcgRIIb$^{-/-}$ mice that either express (Control) or do not express IRF5 (IRF5-KO) or TLR7 (TLR7-KO). During the first five days following tail-vein injection of NTS, at a time when the heterologous antibody response peaked, we euthanized the mice and compared histology, albuminuria, renal immune cell infiltrate and gene expression.

Results: The control mice developed severe glomerulonephritis characterized by massive albuminuria, prominent kidney mononuclear cell infiltration and presence of crescents or necrosis in 28±6% of glomeruli. In contrast, TLR7-KO and IRF5-KO developed significantly less severe disease with crescents/necrosis in only 6±2% of glomeruli ($p<0.01$), and significantly decreased mononuclear cell infiltration (including both patrolling and resident monocytes). Albuminuria was similar in the control and IRF5-KO mice, but significantly lower in the TLR7-KO mice.

Conclusions: IRF5 and TLR7 signaling is required for the development of glomerular inflammation during the heterologous phase of ICGN. However, proteinuria was only ameliorated in the TLR7-KO, but not in the IRF5-KO mice. Therefore an IRF5-independent pathway downstream of TLR7 is responsible for the proteinuria. Consequently, we conclude that the TLR7/IRF5 pathway may represent a novel therapeutic target for the control of glomerular inflammation.

Therapeutic TLR9 Inhibition Prevents the Establishment of Anti-Myeloperoxidase Autoimmunity and the Development of Glomerulonephritis in Mice with Established Autoimmunity

Sharon Lee Ford,[1,2] Poh-Yi Gan,[2] A. Richard Kitching,[1,2] Stephen R. Holdsworth,[1,2] Shaun A. Summers.[1,2] *[1]Depts of Medicine & Nephrology, Monash Health, Clayton, VIC, Australia; [2]Centre for Inflammatory Diseases, Monash Univ, Clayton, VIC, Australia.*

Background: We have shown TLR9 ligation enhances anti-myeloperoxidase (MPO) autoimmunity (AI) and glomerulonephritis (GN) through dendritic cell (DC) activation. We assessed therapeutic TLR9 inhibition on both the development of anti-MPO AI induced through DC vaccination and subsequent development of GN by TLR9 responsive innate effector cells.

Methods: Injection of MPO/Freud's Adjuvant or transfer of MPO/CpG (TLR9 ligand) pulsed bone marrow derived DCs established anti-MPO AI. To stimulate effector cells, intraperitoneal (IP) CpG or MPO/Freud's Adjuvant was injected after inducing anti-MPO AI, prior to triggering renal injury (using anti-glomerular basement membrane globulin). TLR9 signaling was inhibited with an inhibitory oligodeoxynucleotide before both induction of AI and triggering renal injury.

Results: Mice receiving MPO/CpG DCs + IP CpG compared to MPO/CpG DCs + IP GpC (Control) developed heightened immune responses (cells/spleen:5.4±6 vs 3.6±5x10^{8}, $p<0.05$) and renal injury (urea:31±7 vs 11±0.3µmol/L, $p<0.05$; abnormal glomeruli:93±3 vs 15±3%, $p<0.0001$) confirming effector cell TLR9 ligation is required for disease induction and a target for therapeutic inhibition. TLR9 inhibition prevented MPO/FCA induced systemic anti-MPO autoimmunity measured by MPO specific dermal DTH swelling (2.6±1 vs 18.6±3Dmm, $p<0.05$) and decreased frequency of MPO stimulated IL-17A producing cells (6±1 vs 21±3cells, $p<0.01$) compared to control. TLR9 inhibition prevented IL-17A driven AI in mice receiving MPO/CpG DCs (DTH:2.3±1 vs 18.6±3Dmm, $p<0.001$, IL-17A:21±6 vs 43±8cells, $p<0.05$). The TLR9 inhibitor was effective at preventing injury when given to mice with established anti-MPO AI compared to control (DTH:3±1 vs 13±4mm footpad swelling, $p<0.05$, urea:26±1 vs 34±3µmol/L, $p<0.05$, abnormal glomeruli:43±9 vs 79±5%, $p<0.01$).

Conclusions: Therapeutic TLR9 inhibition prevents the development of anti-MPO AI and is a therapeutic option to prevent the development of renal injury once anti-MPO AI is established.

FR-PO973

TLR9 Activation Aggravates Murine IgA Nephropathy; Possible Role of BAFF Mediated Pathway

Yuko Makita, Hitoshi Suzuki, Akiko Takahata, Toshiki Kano, Satoshi Horikoshi, Yusuke Suzuki. *Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan.*

Background: Contribution of Toll like receptors (TLRs) which play a key role in the innate immune system has been discussed in the pathogenesis of IgAN. We recently demonstrated that TLR9 is importantly involved in progression of kidney injuries in IgAN prone mice. On the other hand, role of B cell activating factor (BAFF) is discussed in the pathogenesis of human IgAN. Present study examined the contribution of BAFF in the TLR9 mediated progression of IgAN using IgAN prone mice.

Methods: Commercially available quiescent IgAN prone mice (ddY mice) at 4 weeks of age were used for this study. They were divided into two groups with (n=8) or without (n=8) TLR9 ligand (CpG-ODN) for 12 weeks. Renal histological lesions and serum levels of IgA, IgG and IgA-IgG immune complexes (IC) were evaluated at 16 weeks of age. Serum levels of aberrantly glycosylated IgA was measured by the binding of Sambucus nigra bark lectin and Ricinus communis agglutinin I. Splenic expressions of TLR9, MyD88, BAFF and its receptor (TACI) were also quantitatively evaluated.

Results: CpG-ODN treated, but not non-treated mice, showed mesangial deposition of IgA, IgG and C3. Moreover albuminuria and renal histological scores based on mesangial proliferation and mesangial matrix expansion in CpG-ODN treated mice were significantly higher than those in non-treated mice. The expressions of MyD88, BAFF and TACI were also significantly increased by treatment with CpG-ODN. Interestingly there were significant correlation between BAFF expression and serum levels of aberrantly glycosylated IgA and IgA-IgG IC.

Conclusions: Present study indicated that TLR9 activation exacerbates murine IgAN via increase of aberrantly glycosylated IgA and nephritogenic IC. In addition, present findings also suggested that TLR9 mediated BAFF expression may be involved in the nephritogenic IgA and IC production.

FR-PO974

Key Role of Apoptosis Inhibitor of Macrophage in Phlogogenic Action of Glomerular Nephritogenic IgA in IgA Nephropathy Akiko Takahata,[1] Kento Kitada,[2] Chieko Nogi,[1] Satoko Arai,[2] Yuko Makita,[1] Hitoshi Suzuki,[1] Junichirou Nakata,[1] Satoshi Horikoshi,[1] Toru Miyazaki,[2] Yusuke Suzuki.[1] *[1]Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan; [2]Laboratory of Molecular Biomedicine for Pathogenesis, Center for Disease Biology and Integrative Medicine, Faculty of Medicine, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan.*

Background: Apoptosis inhibitor of macrophage (AIM), a protein mainly produced by macrophages, has been reported to be related to autoimmune diseases as well as arteriosclerosis.

Methods: We evaluated the role of AIM in IgA nephropathy (IgAN) using IgAN prone mice, *grouped ddY (gddY)* (*J Am Soc Nephrol*,2012(8):1364-74). Serum of *gddY mice* was injected to AIM-deficient (AIMKO) and wild-type (WT) mice, and proteinuria and glomerular depositions were evaluated over time. In addition, nephritogenic IgA, produced by *gddY* splenic B cells hybridomas, was injected to AIMKO and WT to perform the same evaluation.

Results: We found excessive expression of AIM in *gddY,* which were co-localized with glomerular IgA. Glomerular IgA depositions were observed in AIMKO and WT 2h after the injections of *gddY* serum and purified nephritogenic IgA. The depositions were cleared soon thereafter in WT but later in KO after being accumulated. However, proteinuria was confirmed in WT, but not in KO. Moreover, $CD45^+$ macrophages infiltration was significantly delayed and less in KO than in WT. To identify the role of macrophages in the clearance of the glomerular immunoglobulin depositions, Gr1-/FcγIV+ macrophages were depleted by injecting WT mice with clodronate liposomes and later with *gddY* serum. However, the depletion of macrophages did not change the degree of glomerular depositions in WT, as in non-depleted WT.

Conclusions: These findings suggest that AIM is a critical molecule in the glomerular IgA clearance and subsequent inflammatory triggering induced by infiltrating macrophages in IgAN. Furthermore, AIM may also contribute to such inflammatory responses by glomerular resident cells such as mesangial cells.

Funding: Government Support - Non-U.S.

FR-PO975

Expression of Mesangial Tissue Transglutaminase Is Independent of Aberrantly Glycosylated IgA in Patients with IgA Nephropathy Akihiro Kato,[1,2] Kazuo Takahashi,[1,2,3] Tomohiro Mizuno,[1,2] Stacy D. Hall,[3] Yoshiyuki Hiki,[4] Kiyotaka Hitomi,[5] Jan Novak,[3] Yukio Yuzawa.[1] *[1]Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan; [2]Meijo Univ, Nagoya, Aichi, Japan; [3]Univ of Alabama at Birmingham, Birmingham, AL; [4]Fujita Health Univ School of Health Sciences, Toyoake, Aichi, Japan; [5]Nagoya Univ Graduate School of Pharmaceutical Sciences, Nagoya, Aichi, Japan.*

Background: It has been reported that tissue transglutaminase (TG2) is essential for mesangial deposition of IgA1 and development of mesangial inflammation in a mouse model of IgA nephropathy (IgAN). We have shown that some IgAN patients have an active form of TG2 in the mesangial area and that mesangial TG2 activity is associated with elevated proteinuria and proliferation of mesangial cells (MC). The impact of aberrantly glycosylated IgA1 on mesangial TG2 expression merits investigation, as circulating immune complexes, including those containing aberrantly glycosylated IgA1, are deposited in the mesangium in IgAN.

Methods: To understand the role of mesangial TG2 in IgAN, expression of TG2 in cultured MC stimulated by sera from IgAN patients with mesangial TG2 activity (IgAN-TG2A), IgAN patients without mesangial TG2 activity (IgAN-TG2N), disease controls (DC), or healthy controls (HC) were assessed. Expression of TG2 in MC stimulated by purified serum IgA1 or enzymatically deglycosylated IgA1 was also assessed. Furthermore, we characterized hinge-region (HR) *O*-glycosylation profiles of serum IgA1 from IgAN-TG2A and IgAN-TG2N using high-resolution mass spectrometry.

Results: MC stimulated with sera from IgAN-TG2A showed more binding of IgA and expressed more TG2 than those stimulated with sera from IgAN-TG2N, DC, or HC ($P< 0.01$). Mass spectrometric analysis identified 13 IgA1 HR *O*-glycoforms with up to 3 galactose-deficient glycans. The number of galactose-deficient glycans was not significantly different between IgA1 from IgAN-TG2A and IgA1 from IgAN-TG2N (0.76 *vs*. 0.79 mol/HR). Enzymatically deglycosylated IgA1 did not change TG2 expression on MC compared to IgA1 from HC.

Conclusions: Sera from IgAN patients enhanced mesangial TG2 expression. Aberrantly glycosylated IgA1 alone was insufficient to increase TG2 expression by MC.

FR-PO976

Characterization of a Signaling Network That Enhances Production of Galactose-Deficient IgA1 in IgA1-Secreting Cells from Patients with IgA Nephropathy Koshi Yamada,[1,2] Colin Reily,[1] Zhi qiang Huang,[1] Joshua Charles Anderson,[1] Milan Raska,[1,3] Hitoshi Suzuki,[1,2] Bruce A. Julian,[1] Christopher D. Willey,[1] Jan Novak.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Juntendo Univ Faculty of Medicine, Tokyo, Japan; [3]Palacky Univ, Olomouc, Czech Republic.*

Background: Interleukin (IL)-6, leukemia inhibitory factor (LIF), and oncostatin M (OSM) cytokines are likely involved in the pathogenesis of IgA nephropathy (IgAN). IL-6/LIF/OSM cytokines activate B cells through similar receptors and the downstream JAK/STAT pathways. We identified key roles of STAT transcription factors in IL-6/LIF/OSM-mediated enhancement of production of IgA1 with galactose-deficient *O*-glycans (Gd-IgA1) by IgA1-secreting cells from IgAN patients. Our study defines how these signaling pathways influence IgA1 *O*-glycosylation.

Methods: IgA1-secreting cells from IgAN patients and healthy controls (HC) were stimulated with IL-6/LIF/OSM with or without JAK/STAT inhibitors. Gd-IgA1 levels were determined by lectin ELISA. Cell lysates from IgAN and HC cells were analyzed by global tyrosine-kinome profiling using PamStation®12 platform and Western blotting. The role of STAT3 or STAT1 in mediating IL-6/LIF/OSM, signaling was confirmed by siRNA knock-down (k/d).

Results: siRNA k/d of STAT3 and STAT1 reduced production of Gd-IgA1 in IgAN cells induced by IL-6 and LIF/OSM, respectively. A specific inhibitor of JAK/STAT signaling reduced IL-6/LIF-enhanced production of Gd-IgA1, but only in IgAN cells. Global tyrosine-kinome profiling identified nine target peptides that were selectively inhibited by the tested JAK/STAT inhibitor in the IgAN cell lysates. Bioinformatics analyses and pathway mapping identified abnormal signaling in JAK/STAT and MAPK cascades as the highest ranked pathway.

Conclusions: IL-6/LIF/OSM cytokines enhanced production of Gd-IgA1 *via* overactivation of JAK/STAT pathways in IgAN cells. Global tyrosine kinomic profiling validated this finding and also indicated participation of MAPK. Elucidating the mechanisms of abnormal signaling associated with Gd-IgA1 production in IgA1-scereting cells may provide new targets for treatment of IgAN.

FR-PO977

TGF-β1 Has the Same Effect with IL-4 on Alteration of IgA1 Glycosylation Through Down-Regulation of Core 1 β1, 3-Galactosyltransferase and Cosmc Jun Xiao. *Nephrology, Dept of Nephrology, the First Affiliated Hospital of Nan Chang Univ, Nanchang, JiangXi, China.*

Background: Aberrantly glycosylated IgA1 plays a pivotal role in the pathogenesis of IgA nephropathy (IgAN). Transforming growth factor-β1 (TGF-β1) mediates the progression of IgAN is well established as a critical IgA isotype switching factor. The effect of TGF-β1 on IgA1 glycosylation has not been illuminated and related mechanism is still unknown.

Methods: We analysed the mRNA levels of Core1ß1, 3-galactosyltransferase (C1GalT1) and its molecular chaperone Cosmc and subsequent O-glycosylation of IgA1 in a human B-cell line stimulated with TGF-β1. The surface IgA1-positive human B-cell line was cultured with different concentration of recombinant human TGF-β1 (5, 10, 15, 30ng/ml). The production and glycosylation of IgA1 were determined by sandwich ELISA and enzymelinked lectin binding assay, respectively. The mRNA levels of C1GalT1 and Cosmc were quantitatively measured by real-time PCR.

Results: IgA1 production was stimulated by low concentration of TGF-β1 (5, 10ng/ml), while was suppressed by high concentration (15,30ng/ml). The terminal glycosylation of secreted IgA1 was altered in response to TGF-β1. TGF-β1 stimulation significantly decreased the mRNA levels of both C1GalT1 and Cosmc.

Conclusions: TGF-β1 may play a key role in controlling glycosylation of the IgA1, and may be partly due to the down-regulation of C1GalT1 and Cosmc.

Epigenetic Modulation of Vitamin D Receptor (VDR) in HIV-Associated Nephropathy (HIVAN) Nirupama Chandel, Kamesh R. Ayasolla, Shabirul Haque, Rivka Lederman, Ashwani Malhotra, Pravin C. Singhal. *Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY.*

Background: HIV has been reported to induce podocyte injury through down regulation of VDR in HIVAN. However, the exact mechanism is not clear. Since HIV has been reported to modulate gene expression via epigenetic phenomena, we hypothesized that HIV would be down regulating podocyte VDR expression in HIVAN via chromatin mofications.

Methods: Renal tissues and cortical sections from four week old control (FVB/N) and HIV-transgenic (Tg26) mice (n=4) were evaluated for the expression of SNAIL, VDR, trimethylationof histone 3 at lysine 4 residue ($H3k4me^3$). Human podocytes (HPs) transduced with either empty vector (EV) or HIV (HIV/HPs) were evaluated for the expression of SNAIL, VDR, and $H3K4me^3$. Stably transfected 293T cells (SNAIL/293T) were evaluated for the same profile. Genomic DNAs of HPs were evaluated for cytosine methylation by Epitect kit and bisulphite pyrosequencing. Composition of SNAIL repressor complex was determined by immunprecipitation (IP) studies. Trimethylation at SNAIL

promoter and binding at VDR promoter were evaluated by ChIP assays. To reverse the VDR expression, HIV/HPs were treated with either VDR agonist (VDA) alone or in combination with either an HDAC inhibitor or a demethylating agent.

Results: Renal tissues of Tg26 mice displayed enhanced expression of SNAIL and H3K4 me^3 but down regulation of VDR. Podocytes in renal cortical sectins of Tg26 mice displayed enhanced expression of SNAIL and down regulation of VDR. HIV/HPs and SNAIL/293T displayed upregulation of SNAIL but down regulation of VDR. HIV/HPs displayed H3K4 trimethylation at SNAIL promoter and enhanced expression of histone deacetylase (HDAC) 1, DNA methyl transferase (Dnmt) 3b. IP studies revealed the association of HDAC1, Dnmt3b, Dnmt1, and mSin3A with the SNAIL. VDR agonists, HDAC inhibitor, and demethylating agents alone could not reverse VDR exprssion optimally, but could do so, when used in combination.

Conclusions: SNAIL recruits multiple chromatin enzymes to form a repressor complexes that down regulate VDR expression in HIV milieu. To upregulate VDR optimally in HIV milieu, reversal of chromatin modifications are deemed essential.

ANCA Disease Patients Demonstrate a Higher Frequency of CD33+ Myeloid Cells with Variable Suppressive Abilities Meghan E. Free,[1] Katie Stember,[2] JulieAnne G. McGregor,[1] J. Charles Jennette,[2] Ronald J. Falk,[1] Maureen Su.[3] *[1]UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Pediatrics, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Myeloid-derived suppressor cells (MDSCs), or CD33+ myeloid cells, have been extensively studied in cancer as potent suppressors of T cell activation. Regulatory T cells do not control T cell proliferation in patients with anti-neutrophil cytoplasmic autoantibody (ANCA) disease, therefore we sought to determine the role of CD33+ myeloid cells in ANCA disease as an alternative suppressive mechanism.

Methods: Analyses were performed using flow cytometry on peripheral blood mononuclear cells (PBMCs) from 63 patients stained with relevant antibodies. Suppressive potential of CD33+ myeloid cells was assessed with a standard T cell suppression assay.

Results: Flow cytometric analysis of PBMCs revealed an increased population of lineage negative, HLA-DR negative, CD11bhigh and CD33+ myeloid cells in patients with ANCA disease compared to healthy controls (mean 2.72% versus 0.18% of PBMCs). This CD33+ myeloid cell population also contained MPO and PR3. Suppression assays utilizing patient CD33+ myeloid cells and autologous T cells have demonstrated variable suppressive capacities with the majority of patients exhibiting modest (30-60%) suppression.

Conclusions: CD33+ myeloid cells are increased in patients with ANCA disease and represent a potential source of T cell suppression not previously investigated. Intriguingly, the patients who demonstrated the highest frequency of CD33+ myeloid cells were those who had sequentially received rituximab and cyclophosphamide.

Endothelial NF-κB Induction by ANCA-Activated Neutrophils Mira Choi,[1] Adrian Schreiber,[1] Claudia Eulenberg,[2] Ralph Kettritz,[1] Claus Scheidereit.[3] *[1]Dept of Nephrology, Charité Berlin, ECRC, Berlin, Germany; [2]Experimental and Clinical Research Center (ECRC), Berlin, Germany; [3]Max-Delbruck Center, Berlin, Germany.*

Background: Activation of the NF-κB/Rel family and subsequent transcriptional upregulation of inflammatory mediators plays a central role in vascular diseases. ANCA vasculitis is a inflammatory condition where ANCA-activated neutrophils (PMN) interact with the endothelium resulting in necrotizing vasculitis. We hypothesized that ANCA-activated PMN promote endothelial NF-κB and vascular inflammation.

Methods: NF-κB activation was assessed by IκBα degradation, EMSA, RT-PCR and IHC. NF-κB was studied in renal tissue from mice and patients with ANCA-induced NCGN, ANCA-stimulated PMN and endothelial cells.

Results: In kidney extracts from mice in which we had induced anti-MPO Ab-mediated NCGN, we observed a significant correlation between the percentage of crescents and NF-κB activity by EMSA (R^2=0.72, n=20). Similar correlations were found for crescents and upregulation of the NF-κB dependent genes TNFa and IκBα. In renal biopsies from patients with ANCA-induced NCGN, we observed strong phospho-p65 staining in the glomerular convolute. Regarding the importance of PMN-EC interactions in ANCA vasculitis, we studied NF-κB activation in PMN and ECs in vitro. Low-dose TNFa priming resulted in little IκBα degradation in PMN, but this effect was not further increased by mAb to PR3/MPO. We studied NF-κB activation in EC when co-incubated with mAb-stimulated PMN and observed significant IκBα degradation in EC (n=10). We confirmed this with human ANCA preparations. Cell-free PMN supernatants were sufficient for endothelial NF-κB activation indicating that direct cell-cell contact was not required. Consequences of endothelial NF-κB activation were the upregulation of endothelial TNFa and IL-8 mRNA and its release as cytokines into the supernatant, which lead to increased recruitment and adhesion of new PMN.

Conclusions: Renal NF-κB activation and NCGN severity were closely correlated. Our in vitro data demonstrate that ANCA-activated PMN induce endothelial NF-κB activity thereby promoting vascular inflammation by recruiting more PMN. Inhibiting endothelial NF-κB may help limiting the ANCA-mediated damage.

Ubiquitin C-Terminal Hydrolase-L1 Controls Dendritic Cell Cross Priming of the $CD8^+$ T Cell Response Anna Reinicke,[1] Malte Mühlig,[1] Pina Schmucker,[1] Timo Lischke,[2] Elisabeth Mettke,[3] Christian Kurts,[3] Hans-willi Mittrücker,[2] Catherine Meyer-Schwesinger.[1] *[1]Nephrology, III. Medical Clinic, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Immunology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Experimental Immunology, Inst for Experimental Immunology, Bonn, Germany.*

Background: Ubiquitin C-terminal Hydrolase-L1 (UCH-L1) is a central deubiquitinating enzyme of the ubiquitin proteasomal system. UCH-L1 is thought to regulate the pool of ubiquitin. Within the kidney, UCH-L1 is *de novo* expressed in glomerular podocytes in human and rodent glomerulonephritis. Mice with constitutive UCH-L1-deficiency exhibit an exacerbated course of immune-complex nephritis suggesting that UCH-L1 affects the ability to mount an effective renal immune response. Aims of the study were 1. To identify the origin of renal tubulo-interstitial UCH-L1-expressing cells, 2. To analyze the response of UCH-L1-deficient mice to a bacterial infection, 3. To analyze the role of UCH-L1 in dendritic cells (DCs).

Methods: Constitutive UCH-L1-deficient mice were generated by Cre-Lox technology. The immunologic phenotype was investigated by challenging UCH-L1-deficient mice with *Listeria monocytogenes*. Cross presentation and cross priming assays were performed *in vitro* and *in vivo*. The DC phenotype was assessed in naïve and stimulated DCs by FACS, Western, proteasomal and deubiquitinase-based activity assays, and real-time PCR.

Results: UCH-L1 is expressed in DCs isolated from kidney and spleen, and in bone-marrow derived cultured DCs. UCH-L1 expression in bmDCs is regulated by IFN-γ and LPS. UCH-L1 activity is upregulated by LPS stimulation while other deubiquitinating enzymes upregulate their activity in the absence of UCH-L1. DCs are specially equipped to cross present antigen to stimulate a $CD8^+$ T cell response. Cross-presentation of cell-associated antigen in UCH-L1-deficient DCs is significantly reduced in vitro and in vivo while activation of a $CD4^+$ T cell response is unaffected. Finally, exposure to *L. monocytogenes* results in a significantly decreased generation of antigen-specific $CD8^+$ T cells.

Conclusions: We describe a hitherto unrecognized role for UCH-L1 in controlling $CD8^+$ T cell activation by DCs.

CD103+ Dendritic Cells Elicit CD8+ T Cell Responses to Accelerate Kidney Injury in Adriamycin Nephropathy Qi Cao,[1] Qing Li,[1] Xin M. Wang,[2] Chengshi Wang,[1] Yuan Min Wang,[3] Stephen I. Alexander,[3] Yiping Wang,[1] David C. Harris.[1] *[1]Centre for Transplant and Renal Research, Westmead Millennium Inst for Medical Research, The Univ of Sydney, Sydney, NSW, Australia; [2]Flow Cytometry Facility, Westmead Millennium Inst for Medical Research, The Univ of Sydney, Sydney, NSW, Australia; [3]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.*

Background: CD103+ dendritic cells (DCs) in non-lymphoid organs exhibit two main types of function, namely maintaining tolerance by induction of regulatory T cells and protecting against tissue infection through activation of CD8 T cells. However, the characteristics and functions of CD103+ DCs in kidney remain unclear.

Methods: Adriamycin nephrosis (AN) was induced in BALB/c mice. The distribution, phenotype and function of kidney CD103+ DCs were assessed in normal and AN mice. CD103+ DCs were depleted by neutralizing CD103-saporin (SAP) antibody in AN mice to examine their role *in vivo*.

Results: In the present study, we showed that CD103+ DCs are one of four subpopulations of renal mononuclear phagocytes in normal kidney; they expressed DC-specific surface markers, transcription factors and growth factor receptors, and were found in kidney cortex but not medulla. The number of kidney CD103+ DCs was significantly increased in mice with Adriamycin nephropathy (AN) and depletion of CD103+ DCs attenuated kidney injury in AN mice. The possible mechanisms underlying the pathogenic role of CD103+ DCs were examined. *In vitro*, kidney CD103+ DCs preferentially primed CD8 T cells, and did not directly induce tubular epithelial cell apoptosis. Adoptive transfer of CD8 T cells significantly exacerbated kidney injury in AN SCID mice, whereas depletion of CD103+ DCs impaired activation and proliferation of transfused CD8 T cells, and thereby reduced kidney injury in AN SCID mice treated with CD8 T cells.

Conclusions: Kidney CD103+ DCs display a pathogenic role via activation of CD8 T cells in Adriamycin nephropathy.

Advanced Glycation End Products Induced the Imbalance Between Th17 and Treg Cells via RAGE Pathway in Diabetic Nephropathy Yanlin Zhang, Ao Cheng. *Dept of Nephrology, The First Affiliated Hospital of Xiamen Univ, Xiamen, Fujian, China.*

Background: There was imbalance of Th17/Treg cells in patients with diabetic nephropathy, but the mechanism was still unclear. Advanced glycation products (AGEs) often accumulated in the patients with diabetic nephropathy, The main purpose of this experiment is to explore whether AGEs can cause the imbalance of Th17/Treg cells throug RAGE signaling pathway.

Methods: (1) Recruitment of 20 healthy adults and 40 diabetic nephropathy patients of CKD stages 3 to 5, and detection AGEs content and ratio of Th17 cells / Treg cells to verify the correlation. (2) Prepared AGE-HSA in vitro and isolated and cultured the initial $CD4^+$ T cells from healthy volunteers peripheral blood to explore the effect of AGE-HSA on the differentiation of initial $CD4^+$ T cell: AGE-HSA with different dose and time stimulated initial $CD4^+$ T cells, or pretreatment with RAGE-siRNA or RAGE neutralizing antibody, and to detect the ratio of Th17 cell and Treg cells by flow cytometry and determine the expression mRNA of RORgt and Foxp3, and the expression of mRNA and protein of STAT3 and HIF-1α.

Results: (1)In patients with diabetic nephropathy, there is accumulation of AGEs and increasing of Th17 cells and the reduction of Treg cells. The ratio of Th17 cells and Treg cell is imbalance (increase in the proportion). There was a positive correlation between the concentration of AGEs and ratio of Th17 cells and Treg cells; (2) the AGE-HSA in a dose dependent manner induced the initial $CD4^+$ T cells to differentiate Th17 cells, and blocking RAGE could mitigate this effect; (3) AGE-HSA increased the expression of RORgt in the initial $CD4^+$T cells, but had no effect on Foxp3. After blocking RAGE, it could inhibits the expression of RORgt induced by AGE-HSA; (4) the expression of STAT3 and HIF-1α was raised in the initial $CD4^+$ T induced by AGE-HSA, while blocking RAGE, expression of STAT3 and HIF-1α. induced by AGE-HSA was inhibited.

Conclusions: In the patients with diabetic nephropathy, there was positively correlated between the content of AGEs and the proportion of Th17 cells and Treg cells, and AGE-HSA can induce the initial T $CD4^+$ cells to generate Th17 cells by RAGE- RORgt signaling.

RORgt Activation in biTregs Promotes Lupus Nephritis Malte A. Kluger, Anna Nosko, Paul Diefenhardt, Boeren Goerke, Matthias C. Meyer, Michael Luig, Rolf A. Stahl, Oliver M. Steinmetz. *Nephrology, Hamburg Univ Medical Center.*

Background: We recently characterized $Foxp3^+$ regulatory T cells, co-expressing the Th17 characteristic transcription factor RORgt, as an independent and bi-functional T cell lineage (biTregs). biTregs secrete both, anti-inflammatory (IL-10, IL-35), but also pro-inflammatory (IL-17) cytokines. Studies in a model of acute crescentic glomerulonephritis suggest that pro-inflammatory biTreg functions are mediated by RORgt. This is of high clinical relevance, since multiple RORgt blocking agents are currently under development.

Methods: Systemic lupus erythematosus (SLE)/Pristane in biTreg^{ROR-}mice.

Results: Time course analyses showed increasing infiltration of biTregs into kidneys of pristane injected mice with a maximum at around 5 months. Subsequently percentages decreased and were back to baseline at 8 months. To study the functional role of RORgt in biTregs, $Foxp3^{Cre}$ x $RORC^{flox}$ mice were generated (biTreg^{ROR-}). Renal histology at 8 months showed severe proliferative glomerulonephritis in pristane injected wild type mice. Histological injury in the biTreg^{ROR-} group, in contrast, was significantly ameliorated. Renal leukocyte infiltration and albuminuria were also reduced by knockout of RORgt in biTregs. As one possible explanation for the improved outcome, we found that biTregs from wild type mice produced pro-inflammatory IL-17 at all observed time points, while biTregs from biTreg^{ROR-} mice did not. In order to assess effects of biTreg expressed RORgt on development of systemic auto-immunity, we studied humoral immune responses. Analyses, however, showed unaltered serum anti-U1-RNP auto-antibody levels of all isotypes. Likewise, renal IgG and complement C3 deposition remained unchanged. This indicates that RORgt activation in biTregs directs renal injury by cellular effectors but does not play a major role for generation of humoral auto-immunity.

Conclusions: Our data provide first evidence for presence and functional importance of biTregs in SLE. Importantly, biTreg expressed RORgt was identified as a factor promoting development of renal injury. Our data therefore favor RORgt directed interventions as innovative new therapeutic option for lupus nephritis.

FR-PO985

IL-2/Anti-IL-2 Complex Attenuates Lupus Nephritis by Expansion of Regulatory T Cells Hye Jin Lim, Ji-Jing Yan, Hyunjin Ryu, Tai Yeon Koo, Kyungok Min, Jae-Ghi Lee, Bohae Kang, Curie Ahn, Jaeseok Yang. *Transplantation Center, Seoul National Univ Hospital, Republic of Korea.*

Background: Regulatory T(Treg) cells play an important role in the pathogenesis and control of autoimmune diseases. Systemic lupus erythematosus(SLE) is an autoimmune disorder characterized by the production of antibodies to self-nucleic acids, immune complex deposition, and tissue inflammation such as glomerulonephritis. We therefore hypothesized that the IL-2/anti-IL-2 complex(IL-2C), a mediator of Treg expansion, can ameliorate progression and reduce the mortality of lupus-prone mice.

Methods: NZWB/F1 female mice progressively produce high levels of autoantibodies and resultant deposition of immune-complexes drives lupus-like glomerulonephritis. NZWB/F1 female mice were treated intraperitoneally with IL-2 /anti-IL-2 mAb(JES6-1) 4 times a week starting at 24 weeks of age, and were analyzed at 36 weeks of age. Lupus-like disease progression was assessed by measurement of proteinuria, dsDNA, cytokine levels and kidney histology,as well as by flow-cytometric analysis of cellular infiltration.

Results: IL-2C induced an effective and sustained expansion of $CD4^+Foxp3^+CD25^+$ Tregs in both kidney and spleen. Compared with the vehicle-treated controls, NZWB/F1 female mice treated with IL-2C showed less proteinuria, less acute and chronic pathological lesions in the kidney and better survival. There were significant differences in glomerular injury, tubular injury and vasculitis scores, as well as in the quantitative analysis of IgG and C3 deposition between the two groups. Disease activity markers were reduced in serum of the IL-2C group. IL-2C treatment reduced plasma cell populations in spleen, inhibition of B and T cell infiltration of the kidney tissue, and suppressed IFN-γ^+CD4^+ and $Th17^+CD4^+$cells in both spleen and kidney. When compared with combination therapy of steroid and mycophenolate mofetil, IL-2C treatment showed similar or better outcomes. Depletion of Tregs with anti-CD25 antibodies abrogated the beneficial effects of IL-2C.

Conclusions: IL-2C protects lupus-prone mice against lupus nephritis by expanding Tregs and suppressing inflammation. Therefore, IL2-C could have a therapeutic potential in lupus nephritis.

FR-PO986

Hyporesponsive T-Cell Phenotype Predicts a Subset of Focal Segmental Glomerulosclerosis (FSGS) Patients Responsive to Rituximab Chang-Yien Chan,[1] Isaac Liu,[1] Lourdes Paula Real Resontoc,[1] Kar Hui Ng,[1] Yiong Huak Chan,[1] Yew Weng Perry Lau,[1] Stanley C. Jordan,[2] Kong Peng Lam,[3] Wee Song Yeo,[1] Hui Kim Yap.[1] *[1]Paediatrics, National Univ of Singapore, Singapore; [2]Cedars Sinai Medical Center; [3]Bioprocessing Technology Inst, A-Star, Singapore.*

Background: Rituximab has been used with variable success in difficult FSGS, but the immunological basis of its efficacy is poorly characterized. This study aimed at identifying T-cell subsets in pediatric FSGS patients in order to define an immunological signature predictive of a favorable response to rituximab.

Methods: 22 FSGS patients (median age 14.4 years, range 6.2-25.0 years) were recruited prospectively to receive rituximab (375mg/m^2 fortnightly to a maximum of 4 doses). Median duration of follow-up was 26.7 months (range 6.5-66.6 months). Baseline immunological subsets were compared with 30 healthy controls, and subsequently examined for association with response to rituximab. Good response was defined as complete resolution of proteinuria accompanied by cessation of prednisolone and calcineurin inhibitors within 3 months.

Results: Of the 22 patients, 12 (54.5%) responded to rituximab therapy. Activated $CD154^+CD4^+CD3^+$ subsets before rituximab were significantly lower in responders (54.9±8.10%) compared to non-responders (78.9±5.18%) (p=0.03) and controls (75.7±2.49%) (p<0.001). IFN-γ^+CD3^+ subsets were similarly decreased in responders (0.55±0.24%) compared to non-responders (7.21±2.11%) (p=0.005) and controls (12.4±2.15%) (p<0.001). IL-2^+CD3^+ subsets were also lower in responders(0.24±0.14%) compared to non-responders (4.42±1.59%) (p=0.007) and controls (6.3±1.5%) (p=0.003). Significant recovery of all 3 activation subsets occurred 3 months post-rituximab treatment. Using ROC curve analysis, activated$CD154^+CD4^+CD3^+$ (AUC 0.82, 95% CI 0.63-1.00), IFN-γ^+CD3^+(AUC 0.86, 95% CI 0.67-1.00) and IL-2^+CD3^+ (AUC 0.82, 95% CI 0.63-1.00) were good predictors of response to rituximab.

Conclusions: We have identified prognostic markers which define a subset of FSGS patients bearing an immunological signature representing hyporesponsiveness to T-cell stimulation, with good response to rituximab therapy.

FR-PO987

Cytokine Profiling in Rituximab-Treated Pediatric Focal Segmental Glomerulosclerotic Nephrotic Patients Wee Song Yeo, Chang-Yien Chan, Hui Kim Yap. *Pediatrics, Yong Loo Lin School of Medicine, National Univ of Singapore, Singapore, Singapore.*

Background: Focal segmental glomerulosclerosis (FSGS) is the most common histological pattern seen in pediatric steroid-dependent and steroid-resistant nephrotic patients. In recent years, rituximab is increasingly used in nephrotic patients who have failed therapy with conventional immunosuppressants. This study aimed to examine the cytokine profile in rituximab-treated pediatric FSGS nephrotic patients and elucidate the cytokine profile differences between responders and non-responders.

Methods: Our study population consisted of 13 pediatric FSGS patients who underwent rituximab therapy. Plasma cytokine profiling was performed on each of these patients utilizing multiplexed Luminex® Cytokine Human 27-Plex assay pre- and post-rituximab therapy. Statistical analysis was performed using Wilcoxon signed-rank test with a p-value of less than 0.05 considered as statistically significant.

Results: Five (38%) of the patients responded to rituximab, defined as having achieved complete resolution of proteinuria accompanied by cessation of prednisolone and calcineurin inhibitors within 3 months. All patients in the study demonstrated an increase in plasma interferon-gamma-inducible protein (IP)-10 levels post-rituximab therapy (554.3±62.4 pg/ml (pre) vs 793.4±125.5 pg/ml (post), p=0.008). Comparing the cytokine profile between responders and non-responders, responders demonstrated a positive mean-fold change in macrophage inflammatory protein (MIP)-1α, in contrast to non-responders which demonstrated a negative mean fold change (0.23±0.16 vs -0.17±0.08, p=0.04). There were, otherwise, no noted significant differences in the other cytokines i) pre-/post-rituximab and ii) between responders and non-responders.

Conclusions: Our study results suggest the development of a pro-inflammatory state in our patients post-rituximab therapy.The increase in plasma IP-10 in patient post-rituximab may account for the phenomenon of rituximab-associated colitis. The finding of increased plasma MIP-1α in responders compared to non-responders is novel. Further mechanistic studies are required to ascertain the role of MIP-1α in the mechanism of action of rituximab.

FR-PO988

Gut-Kidney Axis in the Pathogenesis of IgA Nephropathy Gabriella Lauriero,[1] Eustacchio Montemurno,[1] Maria De angelis,[2] Valentina Maranzano,[1] Lucia Vannini,[3] Loreto Gesualdo.[1] *[1]DETO-Nephrology Unit, Univ of Bari, Italy; [2]DiSSPA, Univ of Bari, Italy; [3]Dept of Agricultural and Food Sciences, Univ of Bologna, Italy.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. It is characterized by deposition of deglycosylated IgA1 and IgG antibodies in the glomeruli and its pathogenesis is only partially defined. Intestinal microbiota could be involved in IgAN, as suggested by the observation that B-cell activation factor (BAFF) transgenic mice had high levels of aberrantly glycosylated serum polymeric IgA, the presence of commensal flora and the circulation of corresponding specific IgA antibodies being essential for the development of IgA deposits. BAFF is an important regulator of B cell maturation, survival and function. The aim of the study was to analyze the role played by gut-kidney axis in the pathogenesis of IgAN.

Methods: 16 healthy controls (HC) and 32 IgAN patients (16 non progressors - NP and 16 progressors - P) were included in the study. Serum creatinine, estimated Glomerular Filtration Rate, 24h-proteinuria and histological lesions following Oxford Classification (MEST score) were analyzed. Gut microbiota, urinary and fecal metabolome of all subjects were characterized by 16S sequencing, Biochrom 30 series amino acid analyzer and gas-chromatography mass spectrometry/solid-phase microextraction (GC-MS/SPME). Galactose-deficient IgA1 (Gd-IgA1) were measured by helix aspersa agglutinin binding assay. BAFF serum levels were quantified by ELISA.

Results: Some traits of the gut microbiota and urinary and fecal metabolome profiles significantly differed between P, NP and HC. Gd-IgA1 and BAFF were significantly higher in IgAN patients, particularly in P, compared to HC (Gd-IgA1: p £0.01 P vs HC; p £0.05 NP vs HC; BAFF: p £0.01 P vs HC). IgAN patients with histological grade at diagnosis M1, E1, S1 and T1 had significantly higher levels of serum BAFF than HC. Moreover, serum BAFF levels were positively correlated with 24h-proteinuria (r =0.47, p =0.0069) and with the levels of fecal phenolic metabolites (r =0.61, p =0.0003).

Conclusions: Gut-kidney axis might play an important role in the pathogenesis of IgAN.

FR-PO989

Intestinal Macrophages Polarized to Activation of Pro-Inflammatory and Had Dysfunction of Phagocytosis Leading to Aggravate Microinflammation and Assist Bacterial Translocation as Carrier in Uremia Rats Lingshuang Sun, Hongli Jiang, Hua Liu, Meng Wei. *Dialysis Dept of Nephrology Hospital, First Affiliated Hospital of Medicine School.*

Background: This study investigated whether intestinal macrophages are related to low-grade inflammation and bacterial translocation (BT) during uremia, and whether probiotics can alter the macrophage activity.

Methods: Male Sprague-Dawley rats were randomly divided into 3 treatment groups: sham, uremia (untreated), and uremia + probiotic.The expression of cell surface antigen CD11a (a.k.a., lymphocyte function-associated antigen 1 [LFA1]), inducible nitric oxide synthase (iNOS), ICAM1, and TGF-β were analyzed by immunohistochemistry. Gene and protein expression of early growth response protein 1 (EGR1) and TLR4 in intestinal specimens were determined. Density of labeled macrophages and tracer bacteria in intestinal and extraintestinal tissues were examined by immunofluorescent microscopy, and macrophage micromorphology were examined by transmission electron microscopy.

Results: Intestinal segments ofthe uremia exhibited markedly high intensity of CD11a, iNOS, ICAM1, and TGF-β staining. Gene and protein expression levels of intestinal TLR4 and EGR1 were also highest in this group. Intestinal segments of uremic rats exhibited high density and broad distribution of tracer bacteria and macrophages. Intestinal macrophages in untreated rats showed fewer cytoplasmic protrusions and pseudopodia. Administration of probiotics resulted in restoration of macrophage classic activation and phagocytosis that was associated with a reduction in BT.

Conclusions: In the uremic state,intestinal macrophages are polarized toward a proinflammatory phenotype that results in low-grade inflammation. Abnormal intestinal macrophage activation and impaired phagocytic function are associated with increased BT. Probiotics may reduce BT by enhancing phagocytosis of intestinal macrophages.

FR-PO990

Linking Pi3K/AKT Signaling to RNase 7 Production and Urinary Tract Sterility Tad Eichler, Robert Easterling, Brian Becknell, John David Spencer. *The Research Inst at Nationwide Children's, Columbus, OH.*

Background: Antimicrobial peptides (AP) play a role in shielding the uroepithelium from uropathogenic *E. coli* (UPEC). We have identified RNase 7 (R7) as a potent, epithelial-derived AP that is secreted by the bladder urothelium and renal intercalated cells. R7 serves as front-line shield to protect the urothelium from UPEC. Currently, there is a limited understanding of the mechanisms that regulate R7 production, and if dysregulated R7 production increases UTI risk. Using a chemical inhibitors transcriptome PCR array, we identified the PI3K/AKT pathway as a unique regulator of R7. Here, we confirm that PI3K/AKT regulates R7 expression and relate changes in R7 to UTI pathogenesis.

Methods: To evaluate the role of PI3K/AKT in regulating R7, we treated primary human renal epithelial cells (REC) with insulin, a known PI3K agonist and/or insulin+wortmannin (wort), a PI3K/AKT inhibitor. PI3K/AKT activation was confirmed by Western blot. qRT-PCR and ELISA quantitated R7. UPEC growth in insulin and/or insulin+wort treated REC media was assessed. Since patients with diabetes mellitus (DM) have decreased PI3K/AKT activity and increased UTI risk, we measured serial urinary R7 levels in new onset Type 1 DM (n=16) before and after starting insulin.

Results: Insulin-dependent phosphorylation of the PI3K/AKT in REC was detected by 1hr. Insulin induced R7 gene expression and protein expression 3-fold (25.23±3.61ng/mL to 72.12±16.20ng/mL, p=0.026). R7 induction was abolished with wort, confirming PI3K/AKT involvement in R7 production. Media from insulin treated REC suppressed UPEC growth compared to media from REC pretreated with wort or vehicle control, suggesting that PI3K/AKT and R7 is involved in UTI pathogenesis. Urinary R7 levels were significantly lower in DM patients compared to healthy controls (13.61±3.94 vs 71.95±15.40ng R7/mg UCr, p<0.02). After 24-hr of insulin, urinary RNase7 levels increased.

Conclusions: PI3K/AKT activation is required for R7 induction. R7 induction suppresses UPEC growth. Diabetics, with decreased PI3K activity, have lower urinary R7 levels. These data may indicate why UTIs are more prevalent with DM and may provide new regulatory targets for UTI treatment.

Serum Acetate and Lipopolysaccharide Levels Correlate with Disease Activity in Patients With Lupus Nephritis Daniel Tak Mao Chan, Ping Lung Chan, Qing Zhang, Kin Yi Au, Desmond Y.H. Yap, Mel Chau, Susan Yung. *Dept of Medicine, The Univ of Hong Kong, Hong Kong.*

Background: Lupus nephritis is a severe manifestation of systemic lupus erythematosus and is associated with poor prognosis. The gut microbiota has been implicated in the etiology of autoimmune diseases. Bacterial products from the gut may enter the circulation and induce inflammatory responses. Acetate is a short chain fatty acid (SCFA) produced by gut microbiota and lipopolysaccharide (LPS) is a component of the outer wall of Gram-negative bacteria. We measured serum acetate and LPS levels and intra-renal expression of their cell surface receptors in lupus nephritis patients to investigate the potential relationship between gut microbiota and lupus nephritis pathogenesis.

Methods: Serum acetate and LPS levels were measured in patients with biopsy-proven severe proliferative lupus nephritis, patients with non-lupus glomerular diseases and healthy controls (n=50 for each group). Intra-renal expression of LPS-binding protein (LBP) and GPR-41 and GPR-43 (SCFA receptors) was also examined.

Results: Serum acetate and LPS levels were significantly higher in patients with lupus nephritis compared to levels in patients with non-lupus renal diseases (P<0.05, for both) and healthy subjects (P<0.01, for both). In lupus nephritis patients, serum acetate and LPS levels were significantly higher during disease flare (P=0.04 and P=0.0015 respectively compared to levels during remission). Serum LPS level correlated with acetate level (r=0.52, P<0.001), and inversely correlated with that of IgG (r=-0.61, P<0.01). Renal LBP, GPR-41 and GPR-43 expression was markedly increased in lupus nephritis patients compared to healthy controls, and was predominantly detected in the tubulo-interstitium, associated with inflammatory cell infiltration, fibrosis and tubular atrophy. LBP, GPR-41 and GPR-43 expression showed similar staining intensities and localization in patients with lupus nephritis and those with non-lupus renal diseases.

Conclusions: Our data suggest that acetate and LPS may be involved in the pathogenesis of lupus nephritis and non-lupus glomerular diseases.

Noninvasive Assessment of Macrophage Activation in Experimental Glomerulonephritis Using Optical Imaging with Near-Infrared Light Serves as a Surrogate of Disease Activity Sebastian Braehler, Dongyue Huang, Matthew David Cheung, Walter J. Akers, Alfred Hyoungju Kim. *Washington Univ School of Medicine, St. Louis, MO.*

Background: Glomerulonephritis (GN) represents a major cause of morbidity & mortality. The standard for diagnosing GN is through renal biopsy, but this is not performed uniformly across many centers. There is an unmet need to identify a noninvasive approach for recognizing GN. Recent advances in deep tissue imaging using probes detected by near-infrared (NIR) wavelengths have enabled the noninvasive probing of biologic activity. Macrophage infiltration of the kidney is observed in early GN and once activated, express the cysteine protease cathepsin B. Thus, renal macrophage activation can be assessed using an NIR probe that becomes fluorescent upon cleavage by cathepsin B. We tested the ability of using NIR optical imaging to assess renal macrophage activation as a noninvasive marker for early-stage GN.

Methods: GN was induced in 129 mice by nephrotoxic serum (NTS) delivered intravenously (IV). Proteinuria was assessed using albumin ELISA & chromogenic creatinine assay. H&E and PAS stained slides of mouse kidneys were observed using light microscopy. Presence of renal macrophages was confirmed using FACS. NIR optical imaging of anesthetized mice was performed following IV administration of a cleavable sensor for cathepsin B & fluorescence intensity of kidney regions quantified.

Results: In mice with uninflamed kidneys, we confirmed the paucity of renal macrophages. Accordingly, there was minimal renal fluorescence signal as determined by fluorescent molecular imaging of cathepsin B activity. 3 days post-NTS administration, we observed a massive influx of macrophages into the kidney, along with nephrotic range proteinuria. This correlated with a significant increase in renal fluorescence intensity signal in NTS mice compared to control mice.

Conclusions: Induction of GN by NTS caused significant macrophage infiltration, which was detected noninvasively by a cathepsin B-activatable probe and NIR optical imaging. These data establish the proof-of-principle that NIR optical imaging may represent a translatable approach to establishing early stages of GN.

Improved Tissue Clearing and 2-Photon Imaging of Mouse Kidneys Reveals Immune Cell Architecture in Nephrotoxic Nephritis Matthew David Cheung, Dongyue Huang, Alfred Hyoungju Kim. *Rheumatology, Washington Univ School of Medicine, St. Louis, MO.*

Background: Tissue clearing approaches such as CLARITY renders tissue transparent, and in combination with two-photon microscopy, enables microscopic visualization deep internal structures within unaltered organs. These cutting edge approaches have drastically improved the understanding of cellular circuits in the brain. However, application of this approach has only recently been described for the kidney. Here, we clear mouse kidneys to better understand the immune cell architecture following induction of nephrotoxic nephritis (NTN) using a modified lipid removal approach that also worked for human kidney fragments.

Methods: 129 mice were injected intravenously with nephrotoxic serum to induce NTN. Mice were perfused with an acrylamide monomer solution to form the basis of the hydrogel. Lipid removal was accomplished using 8% sodium dodecyl sulfate (SDS). An aminoalcohol solution was used to quench light absorbing heme in red blood cells trapped within the tissue. Cleared mouse kidneys were stained with antibodies specific for B cells, T cells, macrophages, and dendritic cells (DCs). Human kidney fragments were incubated in acrylamide monomer solution, then cleared as mentioned above. Cleared tissue was imaged using two-photon microscopy.

Results: Compared to previously published protocols, perfusion of acrylamide monomers into mice significantly accelerated the tissue clearing process. Enhanced tissue clearing was observed when we incubated kidneys in aminoalcohols. We observed vast networks of lymphocytes, macrophages, and DCs in cleared NTN kidneys compared to control kidneys. Human kidneys also were cleared using this approach, and we noted DC networks in healthy donor controls.

Conclusions: We identified a new protocol that enhanced and accelerated tissue clearing in mouse and human kidneys. Using this approach, we found elaborate networks of lymphocytes and monocyte-derived cells in NTN mouse kidneys. We also observed DC networks in healthy human kidney donor fragments. These data demonstrate the utility of tissue clearing in evaluating cellular architecture in mouse and human kidneys.

Natural IgM Mediates Ischemic AKI Lindsey R. Goetz,[1] Jennifer Laskowski,[1] Brandon Renner,[1] Rachel A. Woolaver,[1] Liudmila Kulik,[1] Kazue Takahashi,[2] Matthew C. Pickering,[3] Joshua M. Thurman.[1] *[1]Dept of Medicine, Univ of Colorado Denver School of Medicine, Aurora, CO; [2]Dept of Radiology, Massachusetts General Hospital, Boston, MA; [3]Centre for Complement and Inflammation Research, Imperial College London, London, United Kingdom.*

Background: Glomerular IgM deposition occurs in numerous "non-immunologic" kidney diseases and has been shown in chemical and inflammatory models of injury. We recently demonstrated that complement activation within the kidney leads to neo-epitope formation. Because the alternative complement pathway is activated in renal ischemia/reperfusion (I/R) injury, we hypothesized that complement activation during renal I/R generates neo-epitopes recognized by natural IgM antibodies that then exacerbate inflammatory injury.

Methods: To investigate this hypothesis, we used a 24 minute I/R model.

Results: We first subjected soluble IgM deficient ($sIgM^{-/-}$) mice to renal I/R and found a trend toward less severe injury in these mice vs. wild type (wt) controls (mean BUN of 135 ± 39 [SD] and 152 ± 26 mg/dL, respectively; $n \geq 6$, $p = NS$). To accentuate complement activation in this model, we then exposed mice heterozygous for complement regulatory protein factor H ($fH^{+/-}$) to the same I/R protocol and found that the $fH^{+/-}$ mice sustained worse renal injury and had greater glomerular IgM deposition than wt controls (mean BUN of 114 ± 46 and 63 ± 48 mg/dL, respectively; $n \geq 14$, $p = 0.009$ and mean glomerular IgM RFUs of 44 ± 7 and 22 ± 7, respectively; $n = 8$, $p = 0.0002$). To further evaluate IgM pathogenicity, we induced I/R injury in mice deficient in both factor H and IgM ($fH^{+/-}/sIgM^{-/-}$) and noted a trend toward attenuation of renal injury in the $fH^{+/-}/sIgM^{-/-}$ vs. $fH^{+/-}$ mice (mean BUN of 106 ± 69 and 127 ± 52 mg/dL, respectively; $n \geq 7$, $p = NS$) with data collection ongoing.

Conclusions: These data suggest that natural IgM contributes to ischemic renal injury by binding neo-epitopes generated during complement activation in the kidney. This adds to a growing body of evidence suggesting a common final pathway of IgM-mediated glomerular injury in a variety of "non-immunologic" renal disorders and offers a novel therapeutic target for the treatment of these diseases.

FR-PO995

Activation of Toll-Like Receptor 2 in the Pathogenesis of Contrast-Induced Nephropathy Kristina Angela Rathmell,[1] Altaf-M Khan,[1] Federico Jose Teran,[1] Kathleen S. Hering-Smith,[1] Eric E. Simon,[1,2] Vecihi Batuman.[1,2] *[1]Medicine, Nephrology & Hypertension, Tulane Univ, School of Medicine, New Orleans, LA; [2]VA, SLVHCS, New Orleans, LA.*

Background: Innate immunity mediated by Toll-like receptors (TLRs) is involved in the pathophysiology of contrast-induced nephropathy (CIN). We studied the expression of TLRs and associated molecules in CIN using human renal proximal tubule epithelial cells (RPTECs) and aged diabetic (db/db) mice.

Methods: We cultured RPTECs in normal (5 mM) or high (35 mM) glucose media for 24 h and then exposed them to nonionic (iodixanol or iohexol) and ionic (Urografin) contrast media (CM) at a dose of 25–100 mg iodine/ml for another 24 h in the same media. 24-wk-old male db/db mice were given nonionic CM i.v. (3 g of iodine/kg bw) after 24 h water deprivation. All mice were sacrificed 24 h after CM injection.

Results: The mRNA expressions of TLR2 increased by 2.5 fold ($p < 0.05$), TICAM-1 by 1 fold ($p < 0.01$) and TNF-α by 1.7 fold ($p < 0.05$) in RPTECs exposed to iohexol compared to untreated RPTECs in a dose-dependent fashion. RPTECs in high glucose for 48 h and exposed to iodixanol showed significantly increased apoptosis compared to RPTECS in normal glucose. 24-wk-old db/db mice became obese, polyuric, glucosuric, ketonuric, and had increased GFR, systolic blood pressure, urine NGAL, and renal tubular damage compared to nondiabetic (db/m) control mice. 24 h after iohexol injection, db/db mice showed a significant decrease in GFR, metabolic acidosis and significant increases in serum creatinine, urine and kidney KIM-1 levels and kidney damage histologically compared to control db/db mice. After iohexol administration, the mRNA level of TLR2 was significantly increased by 2.4 fold ($p < 0.01$) in kidney compared to control mice but there was no change in TLR4 expression. The expression of CD11b and CD68 were also significantly upregulated in kidney.

Conclusions: High glucose RPTECs and diabetic (db/db) mice are vulnerable to CIN. Innate immunity mediated by TLR2 plays a major role in the pathogenesis of CIN as demonstrated by *in vitro* and *in vivo* studies. TLR2 may prove to be a promising drug target for the development of new therapeutics against CIN.

FR-PO996

Heparanase Deficiency Improves Renal Function During Experimental Glomerulonephritis Marjolein Garsen,[1] Marilen Benner,[1] Henry Dijkman,[2] Jin-ping Li,[3] Ton J. Rabelink,[4] Israel Vlodavsky,[5] Jo H.M. Berden,[1] Angelique Rops,[1] Michael Elkin,[6] Johan Van der vlag.[1] *[1]Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; [2]Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands; [3]Medical Biochemistry and Microbiology, Uppsala Univ, Uppsala, Sweden; [4]Nephrology, Leiden Univ Medical Center, Leiden, Netherlands; [5]Cancer and Vascular Biology Research Center, Bruce Rappaport Faculty of Medicine, Haifa, Israel; [6]Sharett Inst, Hadassah-Hebrew Univ Medical Center, Jerusalem, Israel.*

Background: Heparanase (HPSE), a heparan sulfate (HS)-specific endoglucuronidase, mediates the onset of proteinuria and renal damage during experimental diabetic nephropathy. Glomerular HPSE expression is increased in the majority of proteinuric diseases. The exact role of HPSE in the development of other inflammatory glomerular diseases is still unknown.

Methods: Here, we evaluated the role of HPSE in two models of experimental glomerulonephritis, being anti-glomerular basement membrane and lipopolysaccharide (LPS)-induced glomerulonephritis, in wild type (WT) and HPSE-deficient mice.

Results: Induction of experimental glomerulonephritis led to an increased HPSE expression in WT mice, which was associated with a decreased glomerular HS expression and albuminuria. Albuminuria was reduced in the HPSE-deficient mice in both models, which was accompanied by a better renal function and less renal damage. Notably, glomerular HS expression was preserved in the HPSE-deficient mice. Glomerular leukocyte and macrophage influx was reduced in the HPSE-deficient mice, which was accompanied by a reduced expression of both Th1 and Th2 cytokines. *In vitro*, tumor necrosis factor (TNF)-α and LPS directly induced HPSE expression and increased transendothelial albumin passage in a HPSE-dependent manner.

Conclusions: Our study shows that HPSE deficiency ameliorates proteinuria and renal damage in experimental glomerulonephritis by preserving glomerular HS expression, and reducing leukocyte and macrophage influx, and by affecting the local cytokine milieu.

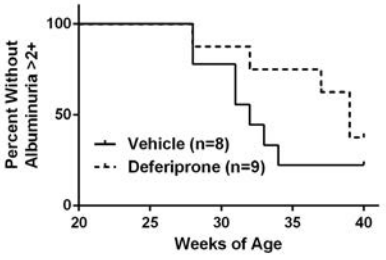
FR-PO997

Iron Chelation as a Novel Renoprotective Strategy in Lupus Nephritis Erika I. Boesen. *Cellular & Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.*

Background: Poorly liganded iron damages tissue via several mechanisms. Multiple iron homeostasis proteins have been proposed as urinary biomarkers of lupus nephritis, and we have previously found that renal tissue iron levels are increased in the (NZBxNZW)F1 mouse model of lupus nephritis. Anemia is also common in lupus patients. Together, these data suggest that dysregulation of body iron homeostasis may occur in lupus. This pilot study tested whether (i) iron chelation is renoprotective in the (NZBxNZW)F1 model of lupus nephritis, and (ii) whether this therapy adversely affects hematological parameters.

Methods: Female (NZBxNZW)F1 mice were treated with the iron chelator deferiprone from 20 weeks of age onwards. Albuminuria was monitored in 24h urine samples collected weekly, and mice were sacrificed at >2+ (>100mg/dL by dipstick) or 40 weeks of age, whichever was sooner. Hematocrit, red cell hemoglobin, plasma non-heme iron concentration as well as kidney and liver iron concentrations were measured at sacrifice.

Results: As shown in Figure 1, there was a trend towards later onset of albuminuria in deferiprone-treated mice compared with vehicle treated mice (median onset of albuminuria 39 and 32 weeks, respectively).



Liver iron concentration was significantly lower in deferiprone-treated mice than vehicle-treated mice, consistent with effective iron chelation. Renal cortical and outer medullary iron concentrations were not significantly different between groups. Unexpectedly, hematocrit was significantly improved by treatment with deferiprone (48±1% versus 39±3% in vehicle-treated mice; P<0.01), whereas red cell hemoglobin and plasma non-heme iron concentrations were not different between groups.

Conclusions: Our pilot data suggest that iron chelation may delay the onset of albuminuria in a mouse model of lupus nephritis without adversely affecting hematological parameters.

IKK2 Inhibition Inhibits the Initiation, but Aggravates the Progression of Crescentic Glomerulonephritis Janine Gotot,[1] Eveline Piotrowski,[2] Gisa Tiegs,[3] Ulf Panzer,[2] Christian Kurts,[1] Friedrich Thaiss.[2] *[1]Rheinische Friedrich-Wilhelms-Univ, Inst of Experimental Immunology, Bonn, Germany; [2]Universitätsklinikum Hamburg-Eppendorf, III Medizinische Klinik, Hamburg, Germany; [3]Univ Medical Center Hamburg-Eppendorf, Inst of Experimental Immunology and Hepatology, Hamburg, Germany.*

Background: The NFκB transcription factor family facilitates the activation of dendritic cells (DC) and $CD4^+$ T helper (Th) cells, which are important for protective adaptive immunity. Inappropriate activation of these immune cells may cause inflammatory disease, and NFκB inhibitors are promising candidate drugs.

Methods: Here, we investigated whether inhibiting the NFκB component IKK2 can attenuate crescentic glomerulonephritis, a severe DC- and Th cell-dependent kidney disease by induction of the paasive and the accelerated NTN mouse model.

Results: Prophylactic pharmacological IKK2 inhibition reduced DC activation, Th cell activation and ameliorated glomerulonephritis in mice. However, therapeutic IKK2 inhibition during ongoing disease, which is relevant for clinical situations, unexpectedly aggravated the nephritogenic immune response and disease symptoms. This resulted from systemic loss of regulatory T cells (T_{reg}), which have been previously shown to protect against crescentic glomerulonephritis and which require IKK2 as well.

Conclusions: In conclusion, although IKK2 inhibition can suppress the induction of nephritogenic immune responses in vivo, it may aggravate such responses in clinically relevant situations, because it also impairs T_{reg} and thereby unleashes pre-existing nephritogenic responses. Our findings argue against using IKK2 inhibitors in chronic glomerulonephritis, and perhaps also in other immune-mediated diseases.

FR-PO999

Transfused M2 Macrophages Ameliorate Renal Injury in Murine Nephrotoxic Serum Nephritis Qiuna Du, Naotake Tsuboi, Yutaka Sugiyama, Seiichi Matsuo, Shoichi Maruyama. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.*

Background: Glomerular leukocyte infiltration is a hallmark of glomerulonephritis. In addition to the effector roles of glomerular macrophages (Mϕ) for tissue injury, recent studies found involvement of alternatively activated macrophages (M2 Mϕ) in resolution of kidney inflammation. The aim of this study is to directly assess the potential of M2 Mϕ to protect against renal injury in murine nephrotoxic serum (NTS) nephritis.

Methods: Bone marrow (BM)-derived Mϕ and mouse iPS-derived Mϕ were obtained under the stimulation of IL-4/IL-13 to differentiate M2a Mϕ with high expression of CD206. FACS and RT-PCR were performed to assess efficient Mϕ differentiation. 0.6 x 10^6 of M2a Mϕ were intravenously transferred 4 days after NTS nephritis induction. Immunostaining was used to detect Mϕ, T cell and neutrophil infiltration. Renal cytokines were determined by ELISA. BM-derived M2a Mϕ from EGFP transgenic mice (EGFP+M2a Mϕ) was exploited to investigate the cell distribution.To investigate in vitro function of M2a Mϕ on other leukocyte subsets, BM-derived M1 Mϕ and splenic CD4+CD25-T cell were co-cultured with EGFP+M2a Mϕ.

Results: M2a Mϕ expressed higher levels of arginase-1 and IL-10/IL-12 mRNAs than M0 Mϕ. Proteinuria was significantly attenuated by injection of M2a Mϕ compared with disease-control mice at day 14 and day 21. Treatment with M2a Mϕ prevented glomerular neutrophil and T cell accumulation. In addition, renal levels of IL-6, MCP-1, IL-1β and TNF-α were significantly decreased in M2a Mϕ-treated mice on day 21. EGFP+ M2a Mjs were seen in the kidney and spleen 24h after cell injection.M1 Mjs were demonstrated phenotypic conversion to an M2a cells following the co-culture with EGFP+M2a Mϕ, while EGFP+M2a phenotype was relatively stable. M2a Mϕ suppressed T-cell proliferation and promoted induction of Tregs in vitro. Immunostaining displayed that Foxp3+ T cells were significantly increased in spleen in mice treated with M2a Mϕ compared with disease control group.

Conclusions: Administration of M2 Mϕ may have therapeutic potency for glomerular injury by further M2 cell conversion and induction of regulatory T cells.

FR-PO1000

Electroacupuncture (EA) and Moxibustion (MO) Decrease the Mortality Rate and Attenuate Inflammation on Already Established Chronic Kidney Disease Josne Carla Paterno, Marcelo Andery Naves, Rafael Luiz, Nestor Schor, Vicente De paulo castro Teixeira. *Nephrology, UNIFESP/EPM, Sao Paulo, Brazil.*

Background: Chronic kidney disease (CKD) is now considered a serious worldwide public health and associated high morbidity and mortality. Traditional Chinese Medicine (TCM) has been increasingly recognized as an effective therapeutic in several fields of medicine. Among its therapeutic strategies are electroacupuncture (EA) and moxibustion (MO). The aim of this study was to investigate the effects of EA and MO on inflammatory factors in CKD model.

Methods: Male wistar rats were submitted to 5/6 nx and divided into three groups: Control (NX): only 5/6 nx; Sham-EA-MO (NX-Sham): 5/6 nx and twice weekly 30 min EA-MO session in sham-points; and EA-MO (NX-ACUP): 5/6 nx and twice weekly 30 min EA-MO session in three real acupuncture points. All procedures began 4 weeks after 5/6 Nx, when the chronic lesions were already established. We measured 24h-proteinuria, tail cuff blood pressure (TBP), renal transforming growth factor-βeta1 (TGF-β1), IL-1, IL-6, IL-2,MCP-1 and mortality rate. The statistical significance of the results was evaluated by ANOVA followed by Tukey test. Values were expressed as mean± SD.

Results:

Parameters	NX	NX-Sham	NX-ACUP
24h-proteinuria (mg/24h) initial	11.4±4.1	12.7±3.1	12.3±4.7
24h-proteinuria (mg/24h) final	198.7±15.3	175.8±9.8	78.3± 10.2*
TBP (mmHg) initial	104.7±6.8	107±8.4	106.5±9.6
TBP (mmHg) final	237.9±13.3	219.9±14.9	135.9±10.7*
TGF-β1 (pg/mL)	572.4±39.2	581.3±45.7	347.9±39.8*
IL-1 (pg/mL)	137.8±11.8	130.8±12.8	40.4±10.9*
IL-2 (pg/mL)	397.8±41.1	391.8±39.8	220.6± 61.2*
IL-6 (pg/mL)	335.8±59.5	297.7±52.6	188.4±54.1*
MCP-1 (pg/mL)	379.6±53.4	369.1±58.3	214.5±43.5*
Mortality Rate (%)	58.9±7.8	54.3±8.9	17.7±6.3*

*(p=<0.05) vs NX and NX-Sham

Conclusions: EA and MO modulated immune and inflammatory responses in CKD, leading to lower production of intrarenal TGF-β1, IL-1, IL-6, IL-2, MCP-1 and decrease mortality rate. Thus, it is reasonable to suggest that EA and MO could be an additional strategy to be employed in CKD.

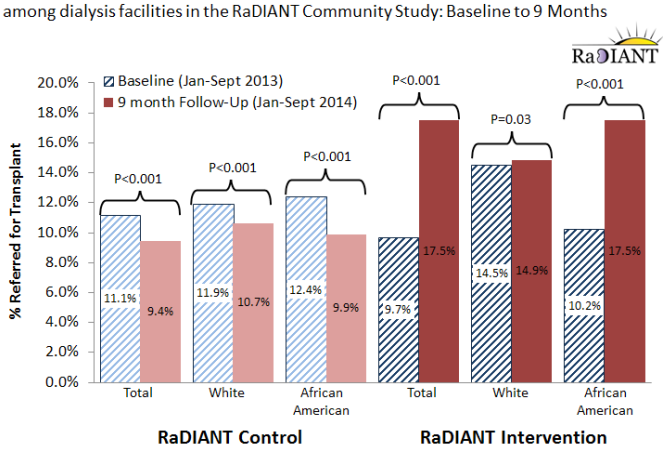
A Randomized Multicomponent Intervention to Reduce Disparities in Transplant Referral: Results from the RaDIANT Community Study Rachel E. Patzer,[1] Leighann Sauls,[2] Jennifer C. Gander,[1] Laura Plantinga,[1] Sudeshna Paul,[1] Eric M. Gibney,[3] Laura L. Mulloy,[4] Stephen O. Pastan.[1] *[1]Emory Univ; [2]Southeastern Kidney Council; [3]Piedmont Hospital; [4]Georgia Regents Univ.*

Background: The Reducing Disparities In Access to kidNey Transplantation (RaDIANT) Community Study is a dialysis facility-level randomized clinical trial to test the effectiveness of a multicomponent intervention in improving kidney transplant (KTx) referral and reducing racial disparities in referral in Georgia.

Methods: In 2013, 134 dialysis facilities were randomized to receive either usual KTx education (n=67) or a multicomponent intervention conducted by, consisting of KTx education and engagement activities targeting dialysis facility leadership, staff, and patients (n=67) over 12 months. Paired *t* tests, overall and by race [white and African-American (AA)], were used to compare referral at 9 months of intervention vs. baseline, in intervention and control facilities.

Results: Facilities that received the intervention had a greater absolute increase in referral over 9 months than facilities that performed usual KTx education (+7.8% vs. -2.5%).

Figure 1. Change in Proportion of dialysis patients referred for kidney transplantation among dialysis facilities in the RaDIANT Community Study: Baseline to 9 Months



A total of 51 of the 67 (76.1%) intervention facilities improved their percentage of patients referred for KTx over the 9 month study period. Intervention vs. control facilities had a greater increase in referral among AA (+7.3% vs. -2.5%) than white (+0.4% vs. -1.2%) patients over 9 months. Among the 26 dialysis facilities that had an AA vs. white racial disparity in referral at baseline, 69.2% no longer had a racial disparity in referral by 9 months.

Conclusions: Data from RaDIANT Community Study intervention facilities suggest that a large, randomized, quality improvement program among dialysis facilities in GA may improve KTx access. Availability of data after 12 months of the intervention will allow final assessment of the effectiveness of the intervention.

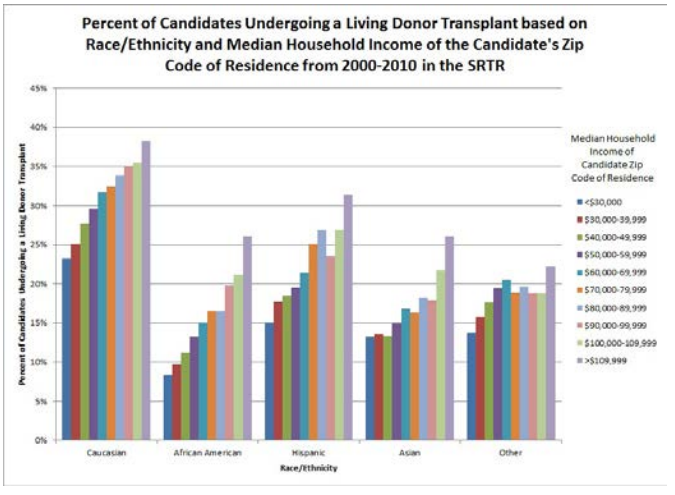
FR-PO1002

Association of Neighborhood Poverty and Living Donor Kidney Transplant Rates by Race Douglas Scott Keith, Angie G. Nishio-Lucar, Gayle M. Vranic. *Medicine, Univ of Virginia, Charlottesville, VA.*

Background: Despite a growing shortage of deceased donor kidneys in the US, living donation (LD) rates have declined steadily since 2004. We sought to understand the impact of candidate socioeconomic environment on living donation rates.

Methods: We identified all candidates listed for kidney or kidney pancreas transplant in the SRTR database from 2000-2010. Data was linked to US census data on median income by zip code. Candidate zip code of residence was used as a surrogate for neighborhood poverty. Univariate and Cox regression analyses were performed to evaluate the independent effects of candidate age, race/ethnicity [Caucasian, African American (AA), Hispanics, Asian, Other], gender, etiology of ESRD, dual listing for pancreas, level of educational attainment, insurance type, PRA, initial listing status (active vs. inactive), dialysis status at listing, first organ procurement organization of listing, year of listing, and median income of zip code by decile. Sensitivity analyses comparing zip code to candidate insurance type and educational status, other markers of socioeconomic status, were performed and yielded similar results.

Results: Increasing median income of candidate zip code was associated with higher rates of LD for all racial and ethnic groups. Overall LD rates were highest among Caucasians followed by Hispanics and Asians. AA had by far the lowest overall LD rates with LD rates of AA candidates living in the wealthiest neighborhoods only slightly higher than rates seen among the lowest quintile median income areas for Caucasians.



Conclusions: Neighborhood poverty is associated with decreased likelihood of LD. This impact was most pronounced among AA. Efforts should be made to remove financial disincentives to living donation to address racial and socioeconomic disparities in access to the life-saving treatment of transplant.

FR-PO1003

Deceased Donor Renal Transplant eGFR at Six Months Has Improved in the Last 13 Years in Spite of Declining Donor Quality Douglas Scott Keith, Gayle M. Vranic, Angie G. Nishio-Lucar. *Medicine, Univ of Virginia, Charlottesville, VA.*

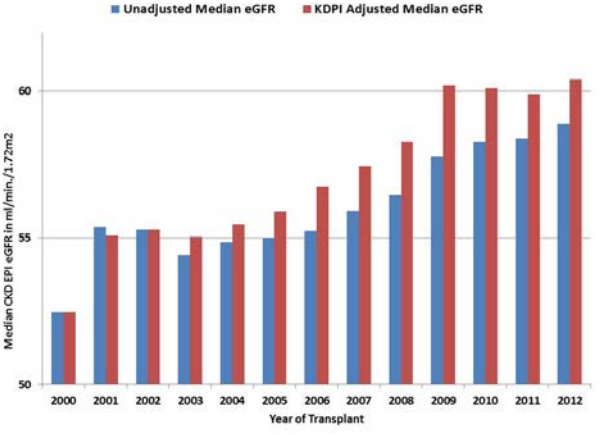
Background: Deceased donor quality has declined in the last decade but long-term graft outcomes are improving. We sought to analyze the trend in graft function at six months post-transplant in relation to this improvement.

Methods: All adult deceased donor kidney transplant recipients with at least six months graft survival recorded in the SRTR databased between 2000 and 2012 were analyzed. The CKD EPI eGFR was determined based on the patient characteristics and serum creatinine at six months post-transplant. KDPI of the donors was also calculated. Linear regression was used to determine the effect of covariates on eGFR.

Results: 111,678 deceased donor recipients were identified. 4918 (4.4%) recipients with no six month creatinine recorded were excluded. The median eGFR improved from 54.5 ml/min./1.72m2 in 2000 to 58.9 in 2012 ($p<0.001$) while the median KDPI increased from 41% to 46%($p<0.001$). The use of tacrolimus/mycophenolate derivative also increased from 33.1% to 89.8%. Every 10 unit increase in KDPI resulted in a 3 ml/min/1.72m2 decline in eGFR.

Linear Regression Analysis	B ml/min/1.72m2	Std. Error
Constant	73.87	0.59
KDPI	-0.304	0.002
Acute Rejection in First Six Months	-10.94	0.23
En Bloc Pediatric Kidney	25.82	0.49
Dialysis in the First Week Post-Transplant	-4.91	0.14
Tacrolimus/Mycophenolate Derivative	1.08	0.58
Neoral/Mycophenolate Derivative	-4.74	0.60
CNI/mTOR	-4.69	0.64
CNI/Azathioprine	-2.93	0.78
Other combination	-2.10	0.60

KDPI adjusted median eGFR increased 13%.



Conclusions: Graft function improved significantly over the 13 year period in spite of declining donor quality and appears to be an important factor in the improvement in long-term graft survival. The transition to tacrolimus/mycophenolate derivative as the dominant maintenance immunosuppression appeared to be an important factor in this improvement.

FR-PO1004

Recipient Age and KDPI Are the Most Potent Predictors of Early Acute Rejection in Deceased Donor Kidney Transplantation Douglas Scott Keith, Gayle M. Vranic, Angie G. Nishio-Lucar. *Medicine, Univ of Virginia, Charlottesville, VA.*

Background: The rate of acute rejection in first six months after deceased donor kidney transplant is now under 10% in the modern era of immunosuppression. We sought to determine the factors predictive of acute rejection in this era.

Methods: All recipients transplanted between 2001 and 2012 in the SRTR database were included in the analysis. Logistic regression was performed to determine the odds ratio of acute rejection in the first six months adjusting for multiple covariates.

Results: The acute rejection rate was 7.1% during the study period. KDPI and recipient age were the most important factors influencing rejection rates with recipients under 30 years old having a rate of rejection more than double that of recipients 60 years or older and recipients receiving donor kidneys with a KDPI over 90% having a 2 fold increase in rejection rate over those receiving a kidney with a KDPI less than 30%.

	Odds Ratio	Lower C.I.	Upper C.I.
Age in Years (Reference 70 or older)			
0-17	2.30	2.00	2.66
18-29	2.18	1.92	2.48
30-39	1.65	1.47	1.86
40-49	1.37	1.22	1.53
50-59	1.19	1.07	1.32
60-69	0.99	0.89	1.11
KDPI Group (Reference 0-9%)			
10-19%	1.00	0.91	1.11
20-29%	1.07	0.96	1.18
30-39%	1.22	1.10	1.36
40-49%	1.33	1.20	1.47
50-59%	1.39	1.26	1.54
60-69%	1.53	1.38	1.69
70-79%	1.52	1.37	1.69
80-89%	1.80	1.61	2.00
90-100%	2.03	1.81	2.28
Other Covariates in model: Recipient gender, race, retransplant, cause of ESRD, duration of dialysis, delayed graft function, pra, HLA mismatch, induction, maintenance immunosuppression, and transplant year			

The only factors in the KDPI determination associated with rejection were donor age, donor hypertension, HCV seropositivity, and black donor race, with age accounting for most of the effect.

Conclusions: KDPI and recipient age are the most important factors associated with rejection. Risk stratification for donor recipient pairs based on age and KDPI should be considered when determining induction and maintenance immunosuppression needs.

Transplantation of Cadaveric Kidneys from Infants and Toddlers into Adults in the Era of Extreme Donor Shortage Jimena A. Blandon,[1] Nader Najafian,[2] Neerja Agrawal.[3] *[1]Nephrology, Cleveland Clinic Florida, Weston, FL; [2]Nephrology, Cleveland Clinic Florida, Weston, FL; [3]Nephrology, Cleveland Clinic Florida, Weston, FL.*

Background: Kidney transplantation is the treatment of choice for patients with ESRD. The number of patients in the waiting list for a deceased donor kidney transplant continues to increase. In this era of extreme donor shortage we present our experience with transplantation of cadaveric kidneys from infant and toddler into adult recipients.

Methods: This was a retrospective study of twelve adult deceased donor kidney transplant recipients from pediatric donors ages 0-5 years. Medical records were reviewed from visits previous to transplantation to the most recent follow up after transplant.

Results: Twelve consecutive adultpatients were transplanted with pediatric en bloc kidneys from donors 0-5 years between February 2014 to February 2015. Ten of the donors were standard criteria brain death (DBD) and two were donors with cardiac dead (DCD), KDPI scores ranged from 47 to 87%, donor age from 6 months to 5 years, weight 6 to 15 Kg. Recipients were equally distributed by gender, average age 56 years, mean BMI 22. All patients were followed in average 6 months to 1 year. In the early post transplant period 9 recipients were noted to have glucosuria with normal blood glucose and mild metabolic acidosis. These findings were noted on average up to 3 to 6 months after transplant and resolved thereafter. Nine patients had follow up renal ultrasound with finding of increase in kidney size 0.3 to 1.2 cm on average at 3-6 months in follow up. There were no perioperative complications, allograft failure, rejection, vascular complications or recurrence of the primary disease. The average serum creatinine remains at 0.89 to date.

Conclusions: We report excellent outcomes after adult kidney transplant from cadaveric donor ages 0 to 5 years of age. Younger age and low weight of the donors did not adversely effect our results. No vascular complications, rejection or allograft loss was noted. All of our patients have excellent allograft function 6-12 months post transplant.

The Role of Dobutamine Stress Echo in Identifying Cardiac Ischaemia, Cardiovascular Events and Role of Subsequent Cardiac Angiography Maria Ventura, Robin Ramphul, Sami Firoozi, Juan Carlos Kaski, Rajan Sharma, Debasish Banerjee. *Renal and Cardiology Depts, St. George's Univ Hospitals NHS Foundation Trust.*

Background: Dobutamine Stress Echo (DSE) is an established method of identifying cardiovascular (CV) risk in patients undergoing kidney transplantation, however the role of coronary angiography (CA) is not clear. The aim of this study was to investigate the role of DSE and CA in predicting cardiac ischaemia and CV events in this population.

Methods: We reviewed data on all patients, 92 out of 233, that were referred between 1/2/2012 and 31/12/2014 and underwent DSE on risk stratification according to our protocol.
